The men who had had influenza in the spring had generally acquired sufficient immunity to resist the more infectious autumn type, while in the ships attacked for the first time, where there had been no immunising previous outbreak, 50 per cent. of the crew at once fell victims. This year (1921) there was an outbreak of influenza among the ships at Portsmouth, the highest attack-rate being 7 per cent.; thus this year it seemed probable that 93 per cent. of the sailors were naturally immune, or had acquired immunity. In a ship the population was so dense and local migration so great that it might be assumed that once a ship was attacked by epidemic influenza, every susceptible on board would get the opportunity of obtaining an effective dose of the specific germ.

There were two types of epidemics in ships attacked in the autumn of 1918. In one the attack-rate was 58 per cent. with many severe pulmonary cases, and 7·5 per cent. case mortality, the predominant organism being a "Gram-positive diplococcus." The other had an attack-rate of 51 per cent. with no deaths or complications of any kind, and influenza-like bacilli were numerous in the sputa. The higher mortality in the first example was probably due to the secondary Gram-positive coccus. The intervals that elapsed between the crests of the two waves of the 1918 to 1919 pandemic was in general longer than that observed ashore in England; for example, 27 weeks elapsed in H.M.S. *Revenge*, 20 in H.M.S. *Royal Sovereign*, and only 16 in London.

Surgeon-Commander Dudley concluded by stating that naval experience and statistics had convinced him that the only sound way of preventing morbidity and mortality in a sea-going fleet was the early and thorough use of a vaccine, combined with the most absolute isolation of infected ships.

Discussion.

The PRESIDENT drew attention to the similarity of the pandemic occurring in 1889 and 1890 to that of 1918 and 1919.

Surgeon Rear-Admiral P. W. BASSETT-SMITH considered that the primary organism made the lung in such a condition as to favour secondary infections. He emphasised the fact that the first wave was mild as compared with the second wave, which was severe. He considered that the first wave conferred considerable immunity in the second wave, and that a mixed vaccine was the most efficacious one in diminishing mortality. In order to ward off an epidemic, immunisation by vaccination should be undertaken widely and early.

Lieutenant-Colonel BERNARD E. MYERS said that in New Zealand dark-skinned persons were first attacked, the native-born New Zealander was the next in the order of attack, while the home-born New Zealander appeared the least susceptible. He considered that a mixed vaccine, containing six or seven varieties of organisms produced a high degree of immunity, that two inoculations were sufficient, and that these should be repeated every six months in order to maintain the immunity.

Squadron-Leader H. E. WHITTINGHAM said that there were three types of influenza attack, as estimated by the leucocyte count. In the first type there was a primary leucopenia, followed later by a leucocytosis; in the second type a leucocytosis was found throughout, while in the third the primary leucopenia persisted. In the speaker's experience this third persistent leucopenic type almost invariably ended fatally.

SECTION OF OPHTHALMOLOGY.

A MEETING of this section of the Royal Society of Medicine was held on May 13th, Dr. JAMES TAYLOR, the President, being in the chair.

Extreme Choroidal Atrophy in High Myopia.

Dr. R. L. REA showed a case of this description in which the fundus was very well seen by Dr. Rayner Batten's instrument. There was a myopia of 30 D. Until he used this apparatus he had had great difficulty in seeing the fine changes in these high myopic fundi; he now had no such trouble.

Treatment of Lacrymal Obstruction.

Dr. D. LEIGHTON DAVIES read a paper entitled "Lacrymal Obstruction: Results of the Anastomotic Method of Treatment (Toti)." He described the operation which Toti was the first to perform for lacrymal obstruction, and set out the circumstances and conditions under which it should be carried out. He had performed the operation 56 times. In 36 patients a complete cure resulted—i.e., there was no epiphora and the canaliculus could be syringed through. In 10 it was partially successful—i.e., the patient was no longer troubled with watering in the eye, yet fluid could not be got through the channel. In 10 the procedure was a failure, for watering of the eye still occurred and there was complete obstruction of the passage. Partial failures were due to contraction of the new opening. It was remarkable that, though an opening was made large enough to admit the tip of the forefinger, this had closed again or become obstructed in three months. This subsequent contraction constituted the weak point in the operation. He had thought it might be due to his having excised too much of the wall of the sac; yet some of the obstructions were not due to the contractions which took place round the mucous membrane, but to a contraction of the inner end of the canaliculus. Every case he had dealt with by operation had been satisfactory for three or four weeks; it was only after this period that contraction began to take place. In comparing this operation with that in which the intranasal route was chosen, he said the latter could have only two features urged in its favour: (1) that it could be done without causing an external wound; (2) that it did not disturb the relations of the sac as much as did the external operation. Against these, however, were the facts that the intranasal operation had to be carried out in a very restricted space, so that it was difficult for the surgeon to see what he was doing: secondly, it often required a preliminary operation to deal with a deflected septum or an enlarged turbinal. It was, in addition, difficult to get through the nasal process of the superior maxilla. Most of the statistics published on Toti's operation gave between 60 per cent. and 70 per cent. of successes. If a case was successful at the end of four months, he felt it would be permanently so; the scar became invisible in two months.

Discussion.—Mr. A. W. ORMOND said he also had found these cases to be unsatisfactory. His experience had been that the less he did the better the result. When pressing over the sac, if there was much muco-pus present, he usually passed a somewhat small probe to ascertain if there was real organic obstruction, and if that was discovered he did no further probing. Many of these cases he regarded as due to strictures which were potential—i.e., caused by inflammation of the mucous membrane and the contiguity, possibly the adhesion, of the walls of the canaliculus to each other. He then instructed the patient to express the sac contents and instil antiseptic drops, such as chloride of mercury and sulphate of zinc. Usually at the end of six weeks of such treatment the discharge had changed from purulent to simply mucoid. If there was still watering and much complaint was made he advised removal of the sac.

Mr. MALCOLM L. HEPBURN thought that in some of these cases there was definite thickening not only of the tissues round the sac, but of bone also.

Mr. W. H. MCMULLEN said the condition in children differed from that in adults in regard to the outlook. His experience had been that the majority of cases due to congenital obstruction opened up spontaneouly in the course of a few weeks or months if the sac contents were expressed and the part was kept moderately clean. When met with in later childhood he had found the treatment of the condition very unsatisfactory: chronic lacrymal dacryo-cystitis in children aged 4 years mostly needed excision of the sac.

Dr. LEIGHTON DAVIES, in reply, said he did not advise the operation unless the patient was very much troubled by the epiphora; he first adopted the means spoken of by Mr. Ormond. Some, however, were so worried by the constant "tearing" that they were willing to submit to anything which promised relief; these he operated upon. He never pressed the operation, because he was not in a position to guarantee success. He believed the so-called "potential" strictures always became organic ones ultimately, though he did not think they became bony. He had not found one case in which this was so in over a thousand dried skull specimens; therefore he thought the stricture was always confined to the soft tissues. He did not think a surgeon was justified in doing Toti's operation on a person under 16 years of age, as it was wrong to interfere with the parts in a growing child. Neither, unless the condition was very troublesome, did he do the operation on old people, because their expectation of life was not very great, and the inconvenience should be borne with.

Aphakia in a Human Embryo.

Miss IDA C. MANN showed a series of remarkable skiagrams and diagrams of a specimen of aphakia in a human embryo of five or six weeks.

The PRESIDENT, Mr. LESLIE J. PATON, and Mr. R. AFFLECK GREEVES congratulated Miss Mann on her exhibit, and the last-named said that in all the congenitally abnormal eyes he had examined a lens or lens capsule was present; he had never seen a case without a lens.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

NAVAL, MILITARY, AND AIR FORCE HYGIENE GROUP.

DEMONSTRATION OF SANITARY APPLIANCES.

A MEETING of this group of the Society of M.O.H. was held on May 6th at the Royal Army Medical College, where a demonstration of sanitary appliances of interest to health officers had been arranged. Lieut.-Colonel H. R. KENWOOD, the President, occupied the chair.

Sir JOHN GOODWIN welcomed the group to the College and to the demonstration which had been prepared for their benefit.

The PRESIDENT spoke of the healthy and happy coöperation which the group by its existence had sustained between medical officers in the services and those in civil employ. The demonstration, organised by the professors of hygiene, tropical medicine, and pathology, was given in the theatre, museum, and laboratories of the R.A.M. College. All exhibits had printed explanatory cards attached and were, moreover, grouped in sections, each in charge of a R.A.M.C. officer, who gave a continuous series of short demonstrations. The sections covered almost the entire range of preventive medicine in its relation to military service under all climatic conditions.

Description of Exhibits.

In the first section there was shown apparatus whereby the energy expenditure of soldiers working under various conditions is estimated, in order to determine the precise food requirements for each stage of training and phase of active operations. An apparatus for ascertaining the effect of load on static equilibrium should be of great value in the prevention of unnecessary fatigue. A fabric impervious to water but freely permeable by air currents was shown as an ideal material for service dress.

The next section, of historical interest, showed all stages in the evolution of means of protection against toxic gases in the field, culminating in the production of the box-respirator.

The section illustrating the life-histories of insect vectors of disease showed the relationship of the mosquito to malaria, while specimens of mosquitoes, blood-sucking flies, lice, fleas, and ticks were so mounted as to facilitate detailed examination. A collection of photographs showed a variety of mosquito-breeding areas, each constituting an especially difficult problem of effective treatment, and each bracketed with its parallel photograph showing the result of the treatment adopted. These afforded striking evidence of the amount of work involved in malaria prophylaxis.

In the section devoted to the prophylaxis and treatment of venereal disease in the army the lethal effect of collosol on living specimens of *Spirochæta pallida* could be followed under the microscope, and the coruscations of the argentum collosol was the subject of an ultra-microscopic demonstration. Photographs from various theatres of war illustrated the clinical appearances of primary lesions of non-genital distribution. The prophylactic packets used in our own forces and those of other nationalities were on view. In other sections demonstrations illustrating the ætiology and pathology of influenza, malaria, Mediterranean fever. kala-azar, oriental sore, dysentery, plague, trypanosomiasis, schistosomiasis, &c., were given. Cultural forms of leishmania and trypanosomes were well shown by dark-ground illumination. The methods of preparation of typhoid-paratyphoid vaccine were illustrated in detail in conjunction with data of the results obtained by it during the recent war. An exhibit of microscopic projection apparatus represented the most recent developments of appliances for instructional purposes. The remaining sections of the exhibition dealt with disinfecting apparatus, the work of the chemical and physical laboratories, field sanitation and army rations.

The Sack Disinfector.

The "sack disinfector" was shown as an apparatus which disinfects and disinfests clothing rapidly and efficiently. It consists of a large steam-tight sack suspended mouth downwards. Clothing is hung from hooks on a detachable wooden disc, which is then drawn by a pulley into the interior of the inverted sack, the mouth of which is partially closed by a purse-string. Steam is generated by combustion of oil in a powerful pressure-stove beneath a small copper boiler, and is led through a flexible tube connected to the upper end of the inverted sack. When a charge of ten suits was placed in the sack, steam emerged from the down-turned mouth after 3½ minutes and thus indicated that disinfection had been completed. Lice placed amongst the articles were found to be killed, and ingenious chemical thermometers placed in the pockets of the garments all indicated that a uniform temperature of 100° C. had been reached throughout the whole charge. The disc having been removed from the sack, the clothing is shaken well and dries rapidly. A portable form of disinfecting apparatus was also shown. It can be carried by bicycle, and can safely be used in the homes of the people, the boiler being placed over the kitchen fire and the sack hung from a support wedged between the door and its frame.

A new departure in the treatment of sullage-water was seen in action and appeared to be giving most satisfactory results, clarification being effected by electrolysis. Amongst the other exhibits was also a Soxhlet for extraction of fat, modified by a device for electric heating. A collection of apparatus for recording temperatures in closed chambers, and a collection of rat poisons were on view.

In the museum were models of a large variety of sanitary appliances used in the field during the war. Another adjacent section showed the "iron rations" of many armies, and the stages of evolution of our own. Samples of various special articles of food (nut-food, anti-scorbutics, &c.) introduced into the ration carried by the members of Shackleton's antarctic expedition on their dash for the South Pole were shown.

The demonstration thus provided an interesting variety of exhibits presented in a convenient form for examination and rapid apprehension.

Intending members of this group of the Society of Medical Officers of Health are invited to communicate with the hon. secretary, Major W. N. W. Kennedy, Town Hall, Croydon.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

OBSTETRICAL SECTION.

A MEETING of this section was held on April 29th, Dr. E. HASTINGS TWEEDY, the President, being in the chair.

Dr. R. E. TOTTENHAM showed a new type of Pelvimeter.

Primary Carcinoma of the Vagina.

Dr. GIBBON FITZGIBBON (Master of the Rotunda) showed a specimen of Primary Carcinoma of the Vagina from a married woman, aged 42, a VII.-para. Last pregnancy, four years ago, was normal. Menses were regular and normal. She was quite well up to two months ago, when slight bleeding from the vagina started and continued. On examination the vulva and perineum were quite healthy. From the right lateral fornix of the vagina there was an ulceration extending slightly on to the posterior wall and down the lateral wall to about an inch and a quarter from the hymen. The ulcer looked very clean, the surface a little irregular and soft, and the edges fairly sharp. There was no evidence of rectal or bladder involvement. The ulcer ran close up to the cervix, but did not encroach on the mucous membrane of it. Per rectum a hard nodule could be felt under the ulcer extending out towards the pelvic wall but mobile. The surface of the ulcer was removed with the curette, and some pieces of the edge were cut away for examination. The pathological report revealed definite cancerous growth showing dense masses of cells.

Operation.—First by the abdomen the ordinary lines of a Wertheim's hysterectomy were carried out until the whole of the vaginal fornices were quite freed. The internal iliac vessels were cleaned and tied at their origins. The patient was then put into the lithotomy position and the vagina divided just inside the hymen all round and separated up, taking as much of the tissue in the ischio-rectal fossæ as possible until the detached upper part was reached, when the whole mass of the vagina and uterus was removed through the vulva. The edges of the vulva were fixed with a few stitches, and the rest of the operation was done by the abdomen. The pelvic peritoneum was closed over a gauze packing. The patient showed a deal of shock, but responded well to a coffee enema followed by small saline enemas during the next 24 hours, and has made an uninterrupted recovery, the abdomen healing perfectly.

A few days before operating on this case Dr. Fitzgibbon operated on another in which the cancer was also primary in the vagina and situated in the lower half, just coming down to the level of the hymen. There was a mass extending out to the ischio-rectal fossa and a hard ring round the vagina, but the ulceration was only lateral. In this case Dr. Fitzgibbon removed the whole vagina from the lesser labium, the edge of the perineum, and the external meatus of the urethra up to the vaginal fornices, and taking the vaginal portion of the cervix. Of the two operations he thought the former was the easier. There was less hæmorrhage owing to the internal iliac vessels having been tied, and the removal of parametrium above the fornices was much more complete and simpler. If he had to operate on cancer of the vagina again he would do the operation—including the removal of the uterus—in three stages, as in this case. It was surprising how little arterial bleeding occurred, only two or three small vessels requiring to be tied, but there was rather profuse venous bleeding for a time, and this was avoided in the case with hysterectomy.

Drs. BETHEL SOLOMONS, D. G. MADILL, and the PRESIDENT spoke, and Dr. FITZGIBBON replied.

Some Notes on the Fibrous and Muscular Attachments of the Vagina.

Dr. LOUIS CASSIDY read a paper on the fibrous and muscular attachments of the vagina. In the course of his communication he showed (by various lantern-slides) that the lower two-thirds of the lateral walls of the vagina are in close apposition with the levatores ani muscles. Interposed between the lateral walls of the vagina and these muscles is a distinct layer of fascia—a portion of the visceral layer of the pelvic fascia—which gains a very definite attachment to the walls of the vagina. This layer is clearly demonstrable, and is intimately blended with the fasciculi of the levatores ani muscles. When followed forwards immediately below the neck of the bladder this fascia will be found to be continuous with the pubo-vesical ligaments; whilst behind it passes into the fascia surrounding the rectum. The surface of this layer of the fascia which rests upon the levatores ani sends prolongations into the muscle to blend with its sheath, thereby indirectly supporting the vagina. The anterior and posterior fascial supports of the vagina resolve themselves into the attachments between the fibrous covering of the posterior wall of the urethra and the anterior fibrous sheath of the rectum behind. The attachment between the wall of the urethra and vagina is a very close one, the structures being morphologically continuous, and is associated with the presence of the dense mass of fibrous tissue which in this region occupies the space left by the disappearance of the female prostate. It is impossible to separate the two structures in their lower two-thirds; the knife must be used. The union of the lower three-fourths with the rectum and anal canal is much less intimate, and permits of easy separation. This relationship between the rectum and vagina is much strengthened at the junction of the rectum and anal canal by the presence of the perineal body. This structure is a wedge-shaped mass consisting of fibro-muscular tissue, and is about one inch in depth, the base of the wedge lying at the skin surface. The vagina pierces the two layers of the triangular ligament and consequently receives firm support from this structure. The muscular attachments of the vagina consist solely of the levatores ani. A transverse section, 4 mm. thick, through the pelvis of a female child, aged 19 months, and taken through the middle of the true pelvis, demonstrates the attachments of fibres of the levatores ani muscles to the lateral walls of the vagina. This relationship is denied by such eminent authorities as Halban and Cruveilher. In conclusion, Dr. Cassidy was convinced that the prevention of a hernial protrusion of the anterior and posterior walls of the vagina will depend on the lateral support it receives from the pelvic fascia and the integrity of the perineal body. He considers this latter structure of paramount importance in the mechanical support of the female pelvic diaphragm. There was one other point to which attention might be drawn—viz., the presence of the transversalis colli, or Mackenrodt's ligaments. These structures can be readily recognised in transverse section through the pelvis of a young female child. That these ligaments do very materially support the upper third of the vagina there cannot be much doubt.

Discussion.

Dr. FITZGIBBON agreed with Dr. Cassidy about the value of the pelvic fascia. Referring to the parietal and visceral layers, he thought that anatomists did not go far enough. He was of opinion that the former merely the covering of the levator ani muscle. actual supports of the vagina were well shown Dr. Cassidy. Dr. Fitzgibbon thought there was as much fascia round the parametrium as in Mackenrodt's ligaments. The parametrium was all muscular, and contained very little fascia, and this was the real support of the vagina.

Dr. BETHEL SOLOMONS was greatly struck by the fact that in Dr. Cassidy's ardent research it had been found that Mackenrodt's ligaments were not the only supports of the vagina. He believed that in further research Dr. Cassidy would find that Mackenrodt's ligaments were probably the most important but not the only supports of the pelvic viscera. The fact that when these ligaments were cut the uterus descended did not prove that they were its only supports, any more than the falling of a body when one leg is removed indicates that it has been supported entirely by the other leg. Dr. Solomons asked Dr. Cassidy what constituted the pillars which were so useful in acting as supports for the bladder in an operation for the cure of cystocele? Did he consider them to be a portion of the pubo-coccygeus muscle with or without fascia, or possibly the detrusor muscle of the bladder?

The PRESIDENT regretted that Dr. Cassidy had not gone further, and demonstrated the attachments of the uterus, but hoped he would do so on a future occasion. In his (the President's) opinion, these fibrous attachments are the supports of the uterus as well as of the vagina. The Master of the Rotunda was right in saying that the strands of fibrous tissue in the pelvis run in every direction, and different names—Mackenrodt's ligaments, utero-sacral ligaments, &c.—have been given to different bundles of these. The theory of the pelvic fascia was fascinating, but it was not "a pelvic fascia." He believed that the uterus is the origin of these strands, which grow out from it in all directions, and they might fitly be described as "uterine tendons." These tendons or ligaments contain muscle, and are under the control of the uterus and, he believed, are its sole support.

Dr. CASSIDY briefly replied.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THE ANNUAL CONGRESS.

THE Annual Congress of the Society was held on May 5th, 6th, and 7th, at the Royal Society of Medicine, and at St. Thomas's Hospital, the event at the latter institution being a demonstration of clinical cases and of apparatus. The chair was occupied throughout by Mr. J. HERBERT FISHER.

Presidential Address: The Personal Equation.

The PRESIDENT, in the course of his address, said the complete ophthalmologist did not, and could not, exist. The subject was wide as the heavens, deep as the ocean; to comprehend ophthalmic science as it now exists it was necessary to enlist as allies the mathematician, the physicist, the chemist, the physiologist, the anatomist, the physician, the surgeon, the urologist, the rhinologist, the dentist, the gynæcologist, the neurologist, the radiologist, the pathologist, the bacteriologist; and within the specialty there was room for every man to exploit to the full the gifts and inclinations with which he was endowed. Perimetry and the examination of the central field of vision for colour defects, absolute and relative scotomata were playing larger parts in investigations, and attention in these matters must be paid to the personal equation. One investigator's charts would rarely be found to coincide with those of another on the same patient: only when a surgeon had stereotyped his own personal equation and controlled that of his patient would his results on the same patient on successive dates be reliable for clinical purposes. Tonometry was tending to replace the digital estimation of intra-ocular pressure, and it was for the younger ophthalmologists to explore its value; but it would not yet quench the older method. The indications for or against operation in a case of chronic glaucoma would never be determined by such variables as the readings on a tonometer or the fluctuations of the blind spot. Too often the ophthalmologist was confronted with the highly myopic sempstress or clerk, incapacitated in later years of their working life by failing vision. A little guidance given to the progressive myope about to embark on the serious business of life might save such a one from a life of misery, ending in shipwreck. Compared with such help the most perfect retinoscopy was of little value. He advocated a closer coöperation with colleagues in general medicine and surgery. The gain from this would be mutual, but ophthalmologists must keep their own house in order: the student must be taught that in dealing with his patients he had responsibilities which he could transfer to no other. Laboratory investigations might supplement his work, but they could not be a substitute for it. The study of disease in the eye could be undertaken only by those who had first been trained in every branch of medicine and surgery; in this there could be no compromise. Ametropia and its results could not be surrendered to the optician. A vision of 6/6 was not proof that there was no disease in the eye.

The address concluded with a sympathetic reference to the recent passing of Charles Higgens and H. E. Juler, and an appreciation of their work. On the motion of Sir ANDERSON CRITCHETT, Mr. Fisher was cordially thanked for his address.

Cyclitis with Glandular Enlargement.

Mr. A. MAITLAND RAMSAY (Glasgow) read a paper entitled: A Case of Cyclitis associated with Swelling of the Parotid Glands. The patient was an unmarried lady, aged 31, who had always enjoyed good health. Strenuous war-work produced ill-health, and one morning her lower eyelids were puffy and her ankles swollen, and the swelling later extended to the knees. The skin was hyperæsthetic, and she had severe intercostal pain. Ten days in bed led to the swelling subsiding, but not the pain, and the latter was only temporarily relieved by large doses of aspirin. The eyes subsequently watered on exposure to light and the sight became dim, and pericorneal injection was obvious, with discoloration of the iris. There were irregularity of the pupil and a deep anterior chamber. There was no impairment of colour-sense, and no gross lesion in the optic disc or retinal vessels, choroid, or retina. Under the idea that it was a deficiency disease, thyroid extract was given, and within a week the sight began to improve. Neither mumps nor diphtheria entered into the problem. Gradually the patient was restored to good health.

Lamellar Cataract with Persistent Pupillary Membrane and Birth Injury.

Mr. J. GRAY CLEGG read a paper by himself and Dr. GORDON RENWICK, entitled Partial Monocular Lamellar Cataract associated with Persistent Pupillary Membrane and Birth Injury. The patient was a boy, whose history had been good. He had an injury at birth, when instruments were used, and on the left eyebrow were three small scars. The lids were much swollen for ten days after birth. The appearances were minutely described with the aid of the epidiascope.

Mr. R. RUSTON JAMES read an interesting contribution under the title: "Sir William Read, oculist to Queen Anne and to George I., Quack, Mountebank," in which he exposed the ambitious claims of Read in the domain of eye diseases.

Flat Neoplasm of the Choroid.

Mr. D. J. WOOD sent, from Cape Town, an account of two cases of Flat Neoplasm of the Choroid. One patient had a widely-dilated pupil, unusual redness of the outer part of the sclerotic, and a detachment of the retina close to the back of the lens. Disease was discovered in the left antrum and in the back part of the lower jaw. There were enlarged glands on the right side of the neck, and a portion excised was thought to be epitheliomatous. X-rays brought about some improvement, but it was evident there was an intra-ocular tumour, as the iris began to bulge on the outer side. Excision of the eye was carried out, and a flat sarcoma was found extending from the optic nerve forward to the iris, with complete detachment of the retina. It went up to the optic nerve, but did not involve it.

Symmetrical Encroachment of the Conjunctivæ on the Corneal Margins.

Mr. WOOD also sent a paper on this subject. The man had been treated by his doctor for cellulitis at the root of the nose; the lids were closed and the eye looked red. After simple treatment, pus was evacuated from the lids, and the condition healed in two weeks, but the eye remained red. The corneal margin was found to be covered by a ring of conjunctiva 2½ mm. wide, and the conjunctival blood-vessels were continued into it. The cornea was dull and covered by a series of reticulated grooves; it was also anæsthetic to a considerable extent. There was neither ptosis nor motor failure; tension was normal. With a fine probe the conjunctiva could be separated from the cornea.

Discussion on the Psychology of Vision in Health and Disease.

Thursday afternoon was devoted to a discussion on this subject. It was opened by

Professor C. SPEARMAN, Ph.D., who dealt with the Retinal Corresponding Points. We see objects in different places, he said, and the question as to the source of this power is one of the most difficult in all psychology. There were two camps of authorities: the "empiricists" and the "nativists." The first of these regarded visual place as the outcome of experience and arising through some such process as "association" or "fusion." The nativists were chiefly physiologists, such as Galen and Johannes Müller, who maintained that this power is essentially innate. According to them, the apparent situation of any visible particle was "specific energy" of the particular nerve fibre stimulated. They claimed that the pathological cases supported their view. The sharp demarcation between the two divisions of thought was now softened down, and it no longer seemed doubtful that our spatial perception was, at any rate partly, determined by factors of a hereditary character. If the origin was to be sought in experience, it must be in some degree that of our ancestors. Wheatstone showed that the pair of images thrown on the two retinæ by a visible particle did not, in general, fall on "corresponding" points of the retinæ; it was, in fact, their very deviation from "correspondence" which furnished our chief criterion of distance and depth. Wheatstone also brought evidence that such a pair of images, though thus falling on "non-corresponding" points, could, nevertheless, be seen as a single image. Straub concluded that the binocular perception of distance must be merely derivative from the far older uniocular perception of it. The present paper offered a new figure in support of Wheatstone's view: *that two retinal points, although truly "corresponding" and normally producing the same visual situation, could nevertheless, under certain circumstances, engender different visual situations.* In fact the spectacle might be presented *of an object moving backwards and forwards, although the place of retinal stimulation remained unchanged.*

Mr. J. HERBERT PARSONS, F.R.S., read a paper on

The Evolution of Visual Perceptions, with Special Reference to the Rôle of Suppression.

Vision was, he said, one of the latest evolved of the senses; it belonged to the group which Professor Sherrington termed "projicient." The earliest evolved *sentient* response to stimuli from the outer world was of the contact order; it had many of the characteristics which had been ascribed to what Head called *protopathic sensation.* Later differentiations were of the epicritic type, leading to more accurate discriminations in various directions. Ophthalmologists were prone to regard the phenomena of binocular vision as themselves sufficient to account for judgments of distance, &c., yet these depended upon standards of posture and direction which were derived from the labyrinth and other parts of the proprioceptive system. Visual sensations could be divided into various kinds, of which the light sense was the most primitive. Peripheral vision was more rapidly fatigued than was central vision; but this rapid fatigue was more than compensated for by the acquisition of heightened mental capacity to appreciate change of local sign; in fact, it might be advantageous. Binocular vision might be regarded as primarily an adaptation in the interests of self-preservation, specially associated with the pursuit and capture of prey, and, to a less extent, in self-defence. Ophthalmology, he said, could not afford to ignore psychology; on the other hand, the only sure foundation for the science of psychology was biology and physiology.

Sir **Robert Armstrong-Jones** related a case of acute melancholia who recovered on being supplied with proper glasses. He had often noted marked hyperæsthesia of the retina accompanying exhaustion. The poison of fevers caused visual rather than any other sensory hallucinations, and the poison of syphilis more often affected the sight than the hearing. In his experience there were far fewer blind than deaf insane persons, and the blind insane were not so suspicious as the deaf, and were more amenable to discipline. He referred to the relief afforded to mental states by appropriate colour-schemes.

Dr. **S. A. Kinnier Wilson** read a communication dealing with psychological peculiarities in certain visual auras in epilepsy, which had been termed by Hughlings Jackson a "*voluminous mental state.*" There were two distinct types which were of interest to the ophthalmologist: (1) the "déjà vu" or "familiarity" type, in which the patient had a strong sense of having seen something new on a previous occasion, with its corollary the "strangeness" type; (2) the "visual memory" type. He related some interesting cases of each.

Dr. **A. S. Percival** also read a paper, in which he dealt with the mechanism of vision.

Amblyopia from Disuse.

Mr. **Frank Juler** read a paper entitled: Amblyopia from Disuse; Visual Acuity after Traumatic Cataract in Children. He said he thought that in certain cases of injury to the lens in young children a line of evidence might be obtained which would satisfy the disputators and perhaps decide whether amblyopia from disuse existed or not. In most cases of traumatic cataract the opacity was rapid, and little light reached the retina after the date of the injury. In some of his cases the lens matter had been evacuated soon afterwards, leaving only an opaque membrane, and in a few an artificial pupil had been made not much later. Even in cases where an artificial pupil had been made, the diffusion of images by the aphakic hypermetropia must be so great that the retinal impulses could not compete with or assist those transmitted from the retinæ of the sound eye, and one would expect these impulses to be neglected, with the *consequent development* of amblyopia from disuse. He had traced a number of cases of juvenile traumatic cataracts, had himself formed a new pupil in some. There was a striking line of difference between the final visual results, depending on the age at which the lens became opaque. None of the eyes which became cataractous before the age of 5 had retained a final central acuity of vision of 6/60. The series showed there is such a disease as amblyopia of disuse, that it affects the eyes of children up to 6 years, that it does not attack eyes after the age of 7 years, and that it causes a real retrogression of the effective power of retinal impulse on the consciousness after the ula has reached an age at which a central vision /8 is normally present.

(*To be concluded.*)

ROYAL MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.

Exhibition of Cases and Specimens.

A meeting of this Society was held in the Faculty Hall on April 15th, the **President** in the chair.

Dr. **Adam Patrick** described a case of

Renal Diabetes.

He said that in the normal person the blood sugar varies from 0·07 per cent. to about 0·15 per cent. or rather more. If the latter concentration is exceeded, sugar appears in the urine. In healthy persons it is difficult to raise the blood sugar above this level. In the diabetic the threshold concentration is habitually exceeded and readings of 0·25 per cent. or much higher may be got. A single reading of this sort is enough to establish a diagnosis of true diabetes. Sugar may also appear in the urine if the renal threshold is lowered, even if the blood sugar does not exceed the normal. In the normal subject the limit of sugar concentration is reached in about an hour, whereas, in the diabetic the maximum is not reached for two or three hours. Dr. Patrick described the case of a man, aged 38, who was found to have glycosuria on examination for life insurance; *five years before sugar had not* been present. The patient's health had been good save for an attack of hæmaturia (cause unknown) 10 years before, when there were no accompanying symptoms. Treatment on the lines suggested by Allen was instituted without great success and the urine only remained sugar-free in a diet approaching starvation. In hospital it was found that on a very restricted diet and with the blood sugar reading only 0·05 per cent., there was a trace of sugar in the urine, and that, on ordinary diet there was abundant sugar in the *urine*, although the blood sugar two and a quarter hours after dinner amounted only to 0·114 per cent. Tested by administration of 25 g. of glucose after a 16-hour starve, the blood sugar curve was normal in type. Dr. Patrick applied the name "renal diabetes" because the glycosuria appeared to be due to a defect in the kidney.

Prof. **J. M. Munro Kerr** *read notes of a case of*

Resection of a Double Uterus

followed by two full-time pregnancies. He also showed the uterus, which had been removed after Cæsarean section. The diagnosis lay between an extra-uterine pregnancy, a myoma complicating a uterine pregnancy, and a pregnancy in the form of a double uterus. The expulsion of the ovum from the right horn of a uterus bicornis settled the matter. The patient had a second miscarriage at a later date from the same horn. Both miscarriages occurred at the third month. The resection of the uterus (bicornis unicollis symmetricus) was done seven months after the last miscarriage. A V-shaped wedge was removed and the two halves of the uterus carefully stitched together. Pregnancy followed soon afterwards and a full-time living child was delivered with the help of forceps, but died owing to injuries sustained at birth. The uterine scar was found to be quite satisfactory on manual examination. Some months later the patient again became pregnant and at full time Cæsarean section was *done and the* uterus removed. Prof. Munro Kerr demonstrated the uterine scar on the anterior and posterior walls of the uterus. These, especially the one on the anterior wall, were satisfactory, but there was a gutter-shaped indenture in the posterior wall over which the placenta was attached. Microscopically much connective tissue was seen in the scars, particularly in the posterior one. The operation has been done on one or two occasions in continental cliniques, but so far as Prof. Munro Kerr knew, not before in this country. The indication for the operation was repeated miscarriages, which seemed to be common in this form of malformation.

DR. JAMES HENDRY described a case of

Amenorrhœa Following Severe Trauma.

In May, 1919, the patient reported three months amenorrhœa without other signs of pregnancy. Her appearance suggested thyroid insufficiency and there was no sign of pregnancy. The disturbances suggesting hypothyroidism were only of recent date. Health previously had been normal. Treatment with thyroid extract was prescribed and continued for a few weeks without improvement, and, in fact, the patient became stouter and stouter and more and more drowsy and apathetic. On again reviewing her history in detail it was discovered that a few weeks before the patient first missed a period she had fallen on the back of her head. Next day her sight was affected and vision was almost lost, but had almost completely returned. Dr. Hendry then thought of a possible lesion of the pituitary gland and administered, orally, tablets of pituitary (whole) gland without any success. By June, 1920, Fröhlich's syndrome had developed — dystrophia adiposo-genitalis, with lethargy and somnolence, and menstruation had returned in a scanty form, lasting one day. A skiagram of the skull to show the sella turcica was obtained and signs of a fracture were seen. The patient could inject 300 g. of glucose without glycosuria. The oral administration of extract of pituitary gland having proved unsuccessful pituitrin administered hypodermically was tried with no success. Five months ago hypodermic injections of antuitrin (Parke, Davis and Co.'s extract of anterior lobe) were commenced and weight is steadily diminishing, although food intake is normal. Regarding sugar tolerance, 120 g. of glucose now produces glycosuria. The special interest in this case is the association of amenorrhœa with hypopituitary function.

Reviews and Notices of Books.

RONTGEN DIAGNOSIS OF DISEASES OF THE ALIMENTARY CANAL.

Second edition. By RUSSELL D. CARMAN, M.D., Rontgenologist, Mayo Clinic; Professor of Rontgenology, University of Minnesota. London and Philadelphia: W. B. Saunders Company. 1920. Pp. 676. 42*s*.

THE first edition of this book appeared in 1917 and was accorded the favourable reception it well deserved, for the work is characterised by a thoroughness and accuracy well up to the high standard of the famous clinic with which Dr. Carman is associated. It has been thoroughly revised in the light of recently acquired knowledge, and new chapters have been added on the hour-glass stomach and the pneumoperitoneal method of examination of abdominal lesions. A valuable feature is the description of those small details of manipulation of the patient during the examination which will best bring out the points most useful in diagnosis. This specially applies to investigations of the stomach and duodenum. The chapter on the X ray diagnosis of gall-stones shows a considerable advance since the publication of the first edition. Throughout the work many new cases are illustrated and described in detail, and the volume is one that cannot fail to be interesting and instructive to medical men who are actively working in abdominal disease from whatever point of view.

A brief passage in the chapter on Interpretation is worth quoting: "The veteran rontgenologist, as well as the novice, is tempted to see too much rather than too little. Once the observer has acquired some familiarity with his work he will find that direct signs of lesions will be manifest quickly or not at all." This comment seems to us significant and well worth remembering.

RADIOLOGIE ET RADIUMTHERAPIE.

By BÉCLÈRE, COTTENOT, and Mme. LABORDE. Paris: A. Maloine et Fils. 1921. Pp. 520. Fr.30.

THIS is the thirty-second volume of a series being published in Paris under the direction of Drs. Sergent, Ribadeau-Dumas, and Babonneix, with the general title, "Traité de Pathologie Médicale et de Thérapeutique Appliquée." An introduction is contributed by Dr. M. Béclère, in which the history and present position of the use of the X rays and radium in medicine is reviewed. X ray diagnosis and X ray treatment are dealt with by Dr. Paul Cottenot, ancien interne des Hôpitaux de Paris, and forms a very complete yet concise treatise on the whole subject. His style is clear and his methods are practical. A number of the radiographs have suffered in reproduction, but this is compensated for by the free use of numerous diagrams, which frequently are more useful for teaching purposes. The section on X ray therapeutics is very complete, forming a sound treatise on a difficult subject, and one that will be of great value to students.

For the final section on radiumtherapie, by Mme. Laborde, we have nothing but praise. The subject is handled with scientific knowledge and thoroughness, and with a clarity that excites our admiration. The volume will be of great interest to those radiologists who like to keep in touch with the work of their French colleagues.

INFANT EDUCATION.

Second edition. By ERIC PRITCHARD, M.A., M.D.Oxon., M.R.C.P. London: Henry Kimpton. 1920. Pp. 226. 6s.

THIS little book originally consisted of lectures which were given to the health visitors of the St. Marylebone Health Society in its earlier days. Since its first edition in 1906, 15 years have elapsed, and during this period its author has seen the wide dissemination of many of the principles therein enunciated and the development of a large school by which they are accepted. Moreover, the rapid and great strides of the infant welfare movement, in which the author has played a prominent part, and the formation of numerous infant welfare centres, have augmented the value of a book which sets out to instruct the lay worker in the elements of infant education based upon considerations of physiology.

From their very nature these lectures of necessity contain a vein of dogmatism. Again, it would be idle to expect that in such a subject the author would be able to steer clear of contentious matter. There emerges, therefore, a book in which there are many statements, clear and definite enough, and admirably expressed, but for which it would be difficult to provide proof and about which there are opinions more conflicting than a perusal would lead the lay reader to suspect.

In the present edition four new chapters have been added, one on the care of the new-born infant, one on the feeding of children at and after weaning, one on the practical details of infant feeding, and one on rickets. The author is an exponent of the caloric method of infant feeding, basing his recommendations as to the total quantities of food to be given at the various months on the supposed caloric requirements of the infant.

There are many who would join issue with regard to this advice. It might reasonably be asked whether we have sufficient knowledge to decide upon the average number of calories required by an infant of a particular age; whether the physiological variations are not too great for the reasoned application of a method so precise in its nature; and whether cow's milk is a food of standard caloric value. "If we wish," writes Dr. Pritchard, "to know, for instance, how much of any particular food should be given to a baby four months old, the calculation can be made in the following manner: On reference to Table. p. 100, we see that the caloric requirements of a child of this age are 612 calories for the 24 hours; from this it is again easy to estimate how much condensed milk, dried milk, or other substitute food must be given in order to supply the required number of calories." Even the adherents of the system, we think, would qualify this statement, for the question of the weight of the baby is omitted and apparently plays no part in the calculation.

Other dicta which we think would provoke criticism from a medical audience is that the food of infants should adhere to the standard of breast milk throughout the first year of life, and that the weaned child requires rather less protein than before weaning. Also that an excessive nitrogenous diet as judged by this standard always leads to pathological results of which "intestinal toxæmia, liver attacks, migraine, neurotic conditions, sleeplessness, offensive breath, muddy complexion, eczema, and a thousand and one ailments commonly regarded as 'gouty'" are cited as typical.

The chapter on rickets includes an exposition of Dr. Pritchard's views on this disorder, long held by him but still awaiting general acceptance. It is an author's privilege to expound his own views in as decisive a manner as he desires, but these few illustrations of the more contentious statements in the lectures—and there are many more of the same category—will serve to show that the lay reader will have no little difficulty in distinguishing how much is accepted as truth and how much is hypothetical.

We hasten to say that the book serves a very useful purpose in stating in simple language and lucid style the principles which underlie infant training, hygiene, and dieting and that any reader who imbibes these principles, even to the written details of their application, will have an eminently safe outlook on the management of healthy infants.

THE GREAT RIDDLE.

The Action and Effects of Natural Forces and Conditions in The Creation. By FRANK HORRIDGE. London: Kegan Paul, Trench, Trübner and Co. 1921. Pp. 98. 3*s*. 6*d*.

WE gather from some reviews and a ballad which are quoted (as an advertisement) in this book that Mr. Horridge is favourably known as a writer of ballads, and the particular one quoted is certainly good. In the volume now before us he has made a new departure and has set about finding a solution to the origin of life, which apparently he considers as "all that we understand under the term creation." His theory is simple enough, but it does not explain the mystery. "We have only to conceive a certain mixture of the elements as having taken place and carbon derived from carbonic acid acting so to speak as the keystone of the physiological arch which constitutes the nucleus and over which the superstructure of organic life in all its various forms is raised and the problem in its initial stage is solved" (p. 25). Mr. Horridge's other thesis is that "every part and organ of the human body or that of any living creature depends for its position, its form, its function and very existence on that which one may term its dynamic environment." Mr. Horridge attributes the transparency of the stratified epithelium of the cornea to the vibratory effects of the rays of light (p. 55), but he does not explain why rays of light beating on other parts of the body do not produce transparency there. On p. 11 he seems to us to use the words "mobile" and "mobility" in the two senses of "easily moved" and, "capable of independent movement." Thus he says "Protoplasm though like air and water in being mobile differs from both in being more complicated," and his conception of the ether seems to us to be extremely hazy. The book is interesting, but we cannot think it of any value as a contribution to knowledge.

DE L'ANAPHYLAXIE À L'IMMUNITÉ.

By M. ARTHUS. Paris: Masson et Cie. 1921. Pp. 361. Fr.20.

IN 1903 Arthus announced that horse serum, harmless to a normal rabbit, causes in a rabbit previously treated with injections of the serum a series of local, general, immediate and remote ill-effects. This fundamental discovery, known since as Arthus's phenomenon, is one of the stones on which the immense superstructure of anaphylaxis has since been reared. The present volume is in no sense an attempt to survey the whole subject with its related topics of protein poisons in general and resistance; it is a synthetic account of the experiments which the author has made himself, most of which have been already described in various periodical publications. The narrative is detailed and the result is more suitable for the technical expert than for the general reader. There are no guinea-pigs with their dramatic deaths from bronchial spasm, but there is an immense amount of information about the effects of different proteins on the blood pressure and respiration of rabbits, data which do not perhaps generally receive the attention they deserve. In an interesting preface the author gives some account of his views on the methods of scientific investigation; he classes theorisers with politicians, though the rest of the book is not nearly as dull as this would lead one to expect. Noteworthy, too, is his belief in the supreme value of solitary meditation—testimony from an old and experienced worker which is of value in these days of ceaseless and restless experimentation.

VETERINARY HYGIENE.

By R. G. LINTON, M.R.C.V.S., Professor of Hygiene, Royal (Dick) Veterinary College, Edinburgh. Edinburgh: W. Green and Son, Ltd. Pp. 429. 26*s*.

HITHERTO veterinary literature has been more concerned with the cure and treatment of disease than its repression and prevention. But there has always been room and need for stressing the lessons of hygiene and for their presentation in comprehensive form. The work under consideration has been written for veterinary practitioners and students and others concerned with the well-being of animals, whilst the requirements of those studying for the Diploma of Veterinary State Medicine have not been forgotten. It may be said at once that Prof. Linton has done his work well, and has, moreover, had the assistance of collaborators who are all experts in their professions.

The book is divided into seven sections, dealing respectively with Water, Meteorology, Sanitation, Air and Ventilation, Building Construction, Preventive Medicine, and Sanitary Law.

The chapter on sanitary law will be of high practical use to the veterinary inspector, as it deals quite comprehensively with all the various Acts and Orders with which he ought to be familiar. The general practitioner will be chiefly fascinated with the chapters on building construction and preventive medicine. Too many men with very imperfect knowledge as to the hygienic requirements of horses, cows, and pigs still have the prime voice in the construction or improvement of their housing. The construction of cowsheds is well discussed in this volume. The reasons given for the adoption of a wide milking passage may be supplemented by the fact that if there is plenty of room dung is less likely to contaminate the milk pail when the attendant passes up and down behind the cows. We may add that the passage should be 3 or 4 inches below that of the cows' beds, as this enables the milker to get more readily at his cows and, moreover, where there is a shallow side to the gutter, the work of shovelling up the manure is rendered easier. We are glad to note that the author lays stress on the need for cleansing and disinfection of premises in cases of swine fever.

Professor Linton shows his knowledge of the conditions met with in practice by the sage remark that "an outbreak of disease is often the only opportunity there is to get a place clean; it is well then to make the most of it." We have not much faith in insect powders either for the prevention or eradication of fleas in dogs or cats, and there are far simpler remedies for lice in horses and cattle than those mentioned by the author, and they are quite as effective.

Professor Linton's book will convince the reader of the importance of adequate representation of veterinary surgeons at the counsels of the Ministry of Health.

HANDBOOK OF OPERATIVE SURGERY.

Second edition, revised and enlarged. By K. K. CHATTERJI, F.R.C.S.I. London: W. Thacker and Co.; Calcutta and Simla: Thacker, Spink and Co. 1921. Pp. 311. Rs.10.

THE author of this handbook does not claim more for it than its title implies. It is necessarily restricted in extent, and many of the operations are described in few words. It is, in fact, rather a summary of operative surgery for the student than a text-book for the practitioner, but to the former it should prove extremely useful. The surgical anatomy of the parts and the indications for operation are clearly and concisely given. The diagrams are good as far as they go. The operations described embody several "author's modifications," but it may be doubted whether these are all original: the methods conform on the whole to the older orthodoxy, and a number of recent modifications of operations other than the author's might have been introduced with advantage. An unusual feature, which should be particularly useful to those for whom the book is primarily intended, is a description of the operations for elephantiasis and tropical liver abscess.

MANUFACTURE OF SUGAR FROM THE CANE AND BEET.

Monographs of Industrial Chemistry. By J. H. P. HERIOT. London: Longmans, Green and Co. 1920. Pp. 426. 24*s*.

IN this interesting and readable volume Mr. Heriot has endeavoured to show that successful practice in the manufacture of sugar is now more than ever dependent on scientific principles, and that these can be studied more effectively outside than inside the factory. Attention is directed to the rather narrow outlook of the British Cane Sugar producer, and it is urged that the student of sugar technology should keep in touch with all branches of sugar production even though he may only specialise in one. This volume will enable him to study the cane and beet sugar industries side by side and to note the progress made in each.

The subject-matter is treated generally and concisely under the following heads. The extraction, composition, and treatment of juice from the cane and beet; the evaporation of water from the juice; crystallisation; extraction of sugar from molasses; by-products; and the refining of cane and beet sugars. A number of good illustrations will be found of material assistance to the reader.

Mr. Heriot has produced a useful volume and it should help in the propaganda which, it is hoped, will result in the development of a beet-sugar industry in this country.

MILK TESTING.

By C. W. WALKER-TISDALE. London: J. North. 1920. Pp. 90. 3*s*. 6*d*.

ALTHOUGH a considerable amount of data have been collected by officers of county councils and other officials bearing on the quality and quantity of milk yielded by cows in herds, it is obviously more satisfactory if the farmer can carry out systematic tests for himself. It is for those connected with the dairy industry who would not describe themselves as analysts, but to whom accurate tests are nevertheless of great importance, that this little volume is intended. The author gives a clear and concise account of the methods usually employed in the analysis of milk. A number of well-selected illustrations will doubtless be an aid to the comprehension of the working details by the non-expert. We think, however, that whilst it is quite possible for the farmer or buyer to learn or to be shown how to work mechanical processes such as the "Gerber" test, he would be wise to leave the chemical technique involved in the examination for preservatives, and in the catalase and reductase tests, to those who are experienced in such matters.

THE ART OF ATTAINING HIGH HEALTH.

Together with Aristology or The Art of Dining. By THOMAS WALKER. Also A Sure Method of Attaining a Long Life. By LEWIS CORNARO. The Pilgrim's Books, No. 5. London: Philip Allan and Co. 1921. Pp. 271. 5*s*.

THESE three essays are rightly included in a series for pilgrims. They set forth ways and means for making the best of our earthly pilgrimage through temperance and the reasoned enjoyments of the pleasures of the table. Health both of body and mind, which connotes a well-spent life and the performance of our duties both to ourselves and to our neighbour, is thus to be attained. The Walker of the nineteenth century and the Cornaro of the sixteenth had both assimilated the old Greek adage of "Nothing too much," and both brought upon themselves the ridicule of acquaintances, but they persevered, and like Bunyan's pilgrim found themselves able to say—

> "Who so beset him round
> With dismal stories
> Do but themselves confound,
>   His strength the more is;
> No foes shall stay his might,
> Though he with giants fight
> He will make good his right
>   To be a pilgrim."

Mr. Walker tells us that during childhood and adolescence, he was scarcely ever free from illness, but one day while reading Cicero's De Oratore some passage suggested to him the expediency of making a study of the improvement of his health. "I rose from my book, stood bolt upright, and determined to be well." And he succeeded to a remarkable degree. He dieted himself and made a practice of taking the air before eating anything—i.e., of going out before breakfast, although he does not seem to have adopted the simple plan of sleeping with his window open. But he attained to such a condition that even when he walked on a dusty road no dust adhered to his feet or shoes or stockings. "By way of experiment I did not wash my face for a week, nor did anyone see, nor I feel any difference. One day I took hold of the branch of a tree to raise my self from the ground, when I was astonished to feel such a buoyancy as to have scarcely any sense of weight." The famous Lord Herbert of Cherbury also attained to a purity of body such that, as he tells us in his autobiography, "the shirts, waistcoats, and other garments I wear next my body, are sweet beyond what either easily can be believed or hath been observed in any one else." Moreover, "I have weighed myself in balances often with men lower than myself by the head, and in their bodies slenderer and yet was found lighter than they." It is but a step from the stage attained by Lord Herbert and Walker to the powers of levitation enjoyed by many holy men both of the West and the East, powers which they could impart to inanimate objects, e.g., in the case of St. Piran, who sailed from Ireland to Cornwall on a millstone.

Mr. Walker having attained high health proceeded to enjoy it with the restraint which is fitting, and hence the discourse upon Dining, which is full of sound sense, although here and there we disagree with him—for instance, where he says that "port-only taken with or without a little water at dinner is excellent." But his remarks upon claret and champagne, together with his insistence on simplicity in everything at table, whether linen, plate, china, glass, or food, with the proviso that everything should be the best of its kind, are outside criticism. One of the good points which he makes is that the fire should be "one of the party," by which he means that no one should have to sit with his back to the fire and the fire screened off, but that the place opposite the fire should be left vacant. Altogether Mr. Walker's papers are well worth reading and remembering, even if the reader may sigh for the days when, in speaking of claret at a famous club, he says, "I would not wish better than that given at the —— at three and sixpence a bottle."

Cornaro's paper has been a classic for centuries, and most of the books upon diet and long life are founded thereon, but we are grateful for a handy reprint.

A Handbook for Nurses.

Sixth edition. By J. K. Watson, M.D. London: The Scientific Press, Ltd. 1921. Pp. 770. 10*s*. 6*d*.

Dr. Watson's Handbook for Nurses is well known to the nursing profession, and the revised edition will be welcomed by probationers and qualified nurses alike. It includes valuable chapters on the Symptoms of Disease, Electricity and Massage, Ear, Nose, and Throat Affections, Skin and Venereal Diseases, whilst every chapter of the former edition has been carefully revised and brought up to date. The number of illustrations has been considerably increased, and an appendix of questions based on the contents of each chapter should prove useful to student nurses.

If the worth of a general text-book may be assessed by its popularity, this book is a valuable contribution to the education of nurses.

Nursing in Eye, Ear, Nose and Throat Diseases.

By A. Edward Davis, A.M., M.D., and Beaman Douglass, M.D. Philadelphia: F. A. Davis Co. 1921. Pp. 346. $2.50.

As a guide, for nurses and students, in the care of the diseases of the eye, ear, nose, and throat, this book is a valuable supplement to a general nursing text-book, and the instruction should be of great help to many who have failed to obtain practical experience in these special branches during their general training. A brief outline of the anatomy and physiology of the special organs treated and a sound chapter on Drugs and Prescribed Treatment should increase the professional interest of the nurse in her duties.

Dr. Davis strongly advocates a general training for all nurses who intend to specialise in ophthalmic nursing.

"Wade In Sanitary."

The Story of a Division Surgeon in France. By Lieut.-Colonel Richard Derby, M.C., U.S.A. London and New York: G. P. Putnam's Sons. Pp. 260. 12*s*.

This is an interesting book, but one which has two great blemishes. First, there is no index, and secondly there is no map, and as the incidents in the book occur in a great variety of places the want of a map is much felt. However, Colonel Derby gives a most graphic account of the work of the American Medical Department, and very good work it seems to have been, especially that for which he was responsible, concerning which he is most modest. It was due to him that the plan was adopted of having a hospital as close up to the firing line as possible. This made it possible for the wounded to be dressed and cared for within some twelve hours or less of the reception of the wound, a practice which resulted in a great saving not only of suffering, but of life. The victims of mustard gas were especially benefited by rapid treatment, and the nearness of the hospital made the surgical practice of complete excision of the wound tract as a preventive of infection practicable, with the result of an enormous diminution in mortality. This plan naturally entailed very rapid evacuation of the wounded and a consequent responsibility upon stretcher-bearers and ambulance drivers, to whom Colonel Derby awards unstinted praise.

Apart from the purely medical and military details in the book, there are a number of remarks upon the social and political aspects of the war and post-war period which are well worth reading, especially in the chapter entitled "Wise in Time," taken from Roosevelt's pregnant motto, "Nine tenths of wisdom consists in being wise in time."

JOURNALS.

Journal of the Royal Naval Medical Service.—From the April issue we learn how important to the fighting service are men with normal binocular vision and binaural hearing. Surgeon Commander W. K. D. Breton tells of the ingenious machine there has been made for him in H.M.S. *Excellent* to measure the degree of stereoscopic vision possessed by men who are to be trained as stereoscopic range-takers. Three needles are arranged in a plane, six metres from the observer and at right angles to the line of sight. The central needle only moves forward or backward, and the small distances through which it can be moved without appearing to the observer to be out of that plane are measured. This may easily be 8 cm. (1·3 per cent.) either way. The smallest error noted in the paper was 5 mm., less than 1 per 1000 of the range, and this range-taker, luckily, also made the most consistent observations. Commander Breton also gives a very clear account of the evolution of stereoscopic vision in animals and in man.—Surgeon Commander E. D. Rutherford tells of the tests that were required in the selection of men to be trained as anti-submarine detectors. They were preferred of ages 18 to 25 (as they trained more quickly), and should have rapid judgment, good hearing, and capacity for localising the direction of sounds and discriminating their intensities. He mentions that of men with enlarged tonsils 90 per cent. failed to reach the required standard of hearing, but only 75 per cent. failed of those who had had their tonsils removed. This paper should be read by all who desire to realise how many and novel were the problems that pressed for immediate solution during the war.—Surgeon Commander A. R. Fisher has a paper on otitis media as it occurred among the cadets at Osborne in the ten years 1910–19. He thinks it a sequela of a "common cold," and to be avoided by the Hancock nose drill. The fauces of the patient are cleaned by a saline douche (glucose, borax, and bicarbonate of soda) at 100° F., from a Higginson's syringe. Such a faucial douche is far more effective than gargles or sprays. In the 10 years quoted there were 303 such cases, and 41 additional in which it was only a complication.—Surgeon-Lieutenant Commander H. E. R. Stephens contributes to the "Naval Medical History of the War" a paper on Immediate Surgery in Fighting Ships. There are no bullet wounds, but the casualties are often large concussions due to the men being hurled by explosions against the sides of the ships. Then there are large ragged contusions by fragments of shell, but these fragments are so often raised to a high temperature in their passing through the sides of the ship that they sear the tissues like a cautery and diminish hæmorrhage. In a pause of the action the wounded can be collected. Then the skin about the wounds can be washed with ether soap, and torn muscle handled, but very gently for fear of the secondary wound shock; this last is best relieved by Bayliss's gum acacia solution. Large vessels must be tied or Cheatle's metal tourniquet applied to the main artery. After checking hæmorrhage, it is best to put a drainage-tube to the bottom of the ragged wound, pack sterile gauze around it, and syringe in eusol every two hours. All burns require to be cleaned up thoroughly under a general anæsthetic; on the completeness of the initial cleansing depends the outcome of the case. Oily applications retard cleaning, and are not recommended for first-aid dressings. But when the burn has been cleaned the best application is carron oil, ℥i., with menthol, gr. 3, and eucalyptus oil, ♏3. Chloroform is the best anæsthetic; for one thing ether is inflammable. This article deals only with immediate surgery; the wounded should then pass to a hospital ship, whose share of the work the next article will consider.

THE LANCET.

LONDON: SATURDAY, MAY 28, 1921.

General Medical Council: The President's Address.

THE summer session of the General Medical Council was opened on Tuesday last, when the President, Sir DONALD MACALISTER, in a short address, reviewed the present position of medical affairs in relation to the special functions and activities of the Council. His address, which will be found in another column, points to the session being both short and business-like, and it is especially good hearing that the disciplinary cases to be inquired into are few and simple. Nothing incites more distrust of the medical profession as a whole, or more ill-informed criticism of the work of the Council, than the consideration of difficult and painful disciplinary cases. And when they are difficult, there must be no thought of economy of time in the desire to elicit the truth, for the marring of a whole professional life may depend on the issue. The debates in such cases produce the wrong impressions. Medical men forget that the disciplinary functions of the Council have been designed to protect the public, and are apt to feel that some of their colleagues are being punished out of all proportion to their offences; the public, assuming the general from the particular, form an unfairly low opinion of professional standards. Therefore it is always good to know that there are few penal cases to be considered by the Council.

The most important part of the President's address deals with medical reciprocity between this country, certain of our own dominions, and certain foreign countries. It is clear that much difficulty attends all laudable efforts towards free trade in medicine throughout the world. During the war this country granted to Belgian practitioners the privilege of practising within British territories, and Belgian medical graduates were made registrable in our British Foreign list. But the Belgian Government having now decided to require British practitioners to obtain a Belgian qualification as a condition of practice in Belgium, that piece of medical reciprocity has come to an end. In actual numbers of practitioners the *rapprochement* was not strong: but it was real, and we can only regret its quick cessation. On the other hand, there seems to be an opening for a professional understanding with Spain, a country which the course of modern history has probably been benefiting. The Executive Committee of the Council is making inquiries as to the position which practitioners, who are registered in the United Kingdom, would enjoy in Spain, and it will be interesting to learn what course of study or what examinations are likely to be required by the Spanish Government from our qualified medical men. Among our own dominions the question of reciprocity is to the fore in India and in South Africa, and, as on the continent, the position is alternately good and bad. For many years the diplomas of certain Indian universities have been recognised by the General Medical Council as affording registrable qualifications in this country, but it has been brought lately to the notice of the Council that at some of these universities the standards both of training and of examination in regard to midwifery have fallen below those which it is necessary to demand for registration. The Council has notified the universities that unless their curriculum in connexion with midwifery is raised to a satisfactory level, recognition in this country will be discontinued. With regard to the Union of South Africa, the story is exactly the reverse. The Union admits to its register medical practitioners who are registered in the United Kingdom, and is desirous that the degrees of its own universities should be accepted as registrable qualifications at home. Owing to the development of medical education in the Union, the Executive Committee of the Council has advised that Part 2 of the Medical Act can now properly be applied to South Africa, when the Council will be free to recognise such South African medical degrees as fulfil the prescribed conditions. The chance of real and widespread medical reciprocity between all civilised nations is as a whole growing stronger, because of the many directions where its institution is now ardently desired. The leaders of medicine will keep their eye on universal reciprocity as an ideal for the future, and we trust the practical sense of doctors to be ranged against any attempt to bolster up inadequate training, so as to secure a too previous entrance into national comity.

The third point to which we would draw attention in Sir DONALD MACALISTER's address is the prominence which he gives, and gives rightly, to dental affairs. The dental profession, though increasing in popularity with students, is still undermanned, and this fact forms one of the great arguments in the public eye why the Dentists Bill, introduced three weeks ago, should promptly become law. The Dental Committee of the Council has had under its consideration all the drafts of that Bill during its preparation in the Ministry of Health, and as a result Sir DONALD MACALISTER considers the projected legislation to constitute a great step towards the removal of dangerous abuses. The abuses are those which have attended the practice of charlatans who have filled the gaps left by the paucity of trained men. The view is one that we have taken in our columns, but the inclusion of a number of additional dentists in a professional roll will not meet the situation in a satisfactory way unless the names of those added are subjected to rigid scrutiny.

◆

Irradiation and Safety.

LIFE cannot be made safe, even for heroes. Youth is too adventurous and, by the time prudence has set in, the seeds of disease have often been sown or habits of body acquired which sooner or later impair health. It is an interesting speculation whether life can ever become safe, for with each new phase of culture fresh risks arise and the means devised for their avoidance, however prompt and ingenious, are necessarily a little behind the risks and never quite catch them up. So it has been with the application of X rays and other rays of short wave-length in medicine and industry. Like any other powerful therapeutic agent, irradiation may damage the healthy cells of the body while directed at diseased cells or parasitic invaders. It is for us to increase the working margin between toxic and therapeutic dose, to ensure the beneficent curative effect and eliminate the harmful by-effects. Much has already been done, and it is a mercy that the searchlight of popular interest has only been turned on the scene in the third or fourth act. The first act of unprotected X ray exposure was on a small scale something very like tragedy. Dr. IRONSIDE BRUCE's lamented death two months ago awoke such startled interest just because in the meantime the use of irradiation had become a commonplace and scores of workers in many lands were using it unscathed on thousands of patients. The public in any case has little to fear since the risk is manifold for the operator.

The time has now come for the standardisation of protective measures and their enforcement wherever X rays and radium are employed, whether in the arts or in medicine. An important committee has been formed composed of radiologists, physicists, pathologists, and others, nominated by the Electro-therapeutic Section of the Royal Society of Medicine, the British Association for the Advancement of Radiology and Physiotherapy, the Rontgen Society, the National Physical Laboratory, and the Institute of Physics, which has come into existence just in time to take its share in a field of work peculiarly its own. The membership of the Committee is as follows:—

Sir Archibald Reid, radiologist to St Thomas's Hospital, and Dr. Robert Knox, radiologist to King's College Hospital, representing the British Association for the Advancement of Radiology and Physiotherapy; Dr. S. Gilbert Scott, radiologist to the London Hospital, and Dr. Stanley Melville (hon. sec.), radiologist to St George's Hospital, representing the Electro-therapeutic Section of the Royal Society of Medicine; Dr. Harrison-Orton, radiologist to St. Mary's Hospital, and Mr. Cuthbert Andrewes, representing the Rontgen Society; Prof. S. Russ, physicist to the Middlesex Hospital, representing the Institute of Physics; Dr. G. W. C. Kaye, representing the National Physical Laboratory; and Dr. J. C. Mottram, pathologist to the Radium Institute.

A preliminary meeting of this X Ray and Radium Protection Committee was held last week at the Royal Society of Medicine, under the chairmanship of Sir HUMPHRY ROLLESTON, when it was decided to issue as soon as practicable a considered statement as to the urgency of affording adequate protection to the worker, indicating the best means whereby this may be carried out. A subcommittee has been set apart for this purpose. The Committee itself proposes the much larger task of collecting data bearing on the effect of irradiation, with particular reference to protection, of carrying out any necessary research, and of acting in a consultative capacity, issuing reports at any useful stage of its investigations.

The Committee is more particularly interested in the question of irradiation as it affects the worker, the patient not being exposed to anything approaching the same risk. It realises that there must always be individual cases in which idiosyncrasy is a danger, and occasional failure of the personal element is hardly to be avoided in a workaday world. The first instalment of information may be expected to bear on such matters as the position of X ray rooms, their cubic content and standard of ventilation, the condition of the blood of workers, and the need for regularisation of work and ample supply of fresh air. In the meantime, any institute which feels anxious as regards the standard of its own protective equipment should apply for guidance to the hon. secretary of the Committee at 9, Chandos-street, London, W.1.

Anaphylaxis and Immunity.

IT was a happy coincidence in the series of independent post-graduate lectures being held at the Institute of Pathology and Research, St. Mary's Hospital, London, that a discourse emphasising the peculiar value of the study of symptoms[1] should be followed by one illustrating the confusion to which consideration of symptoms alone may give rise. If the same protein is introduced respectively into a guinea-pig, a rabbit, and a dog, all having been sensitised by a previous injection, the actual symptoms produced are in each case severe, but differ so widely for each species that, were they not known to have been provoked experimentally by the same agent, no one would suspect their common origin. The guinea-pig dies of asphyxia—traceable to constriction of the bronchioles—after a series of deep gasps for life, which leave the lung permanently distended with air. The rabbit dies of right-heart failure, due apparently to the contraction of the muscular coat of the pulmonary arteries; while in the dog the blood pressure falls to 30 mm., the liver is greatly engorged, and the animal presents a typical picture of intense circulatory shock. Nor are these phenomena even peculiar to anaphylaxis; other substances, various cleavage-products of proteins, and even a simple base, histamine, produce similar symptom-complexes—differing in each species but constant for the same species. Dr. DALE showed that these superficially different complexes could be connected as dependent on the contraction of plain muscle fibre and the poisoning of capillary endothelium, the incidence of these effects being differently localised in the different species. He proceeded to discuss the present position of the theories of the cause and significance of anaphylaxis as derived from experimental research. While the injection of certain toxic substances gives rise to similar symptoms, the characteristic feature of anaphylaxis is its occurrence in connexion with substances not normally poisonous. Dr. DALE gave a succinct and lucid account of the theories of the production of an anaphylatoxin and of the experimental evidence for and against Friedberger's hypothesis of its production as the result of the formation of an antigen-antibody complex in the body fluids, and then explained in rather more detail his reasons for believing that the reaction between antibody and antigen takes place within the body cells in anaphylaxis, and that this location of the reaction is the cause of the symptoms.

The technique which he had devised for studying this reaction consisted in the use of isolated uterine muscle, perfused free from blood, as an indicator. Plain muscle from an anaphylactic animal gives in vitro as specific and delicate a reaction as the animal itself. If to such a preparation suspended in Ringer's solution there is added the antigen to which the animal has been sensitised, the plain muscle contracts promptly and maximally; no other antigen has this effect, nor does the addition of antigen to the muscle derived from a non-sensitised animal give rise to any contraction. The specificity of the phenomenon is thus reproduced in vitro, whereas its delicacy can be estimated by the fact that a solution of 1 in 500,000,000 gives a recognisable reaction. Dr. DALE, after describing the experiments which convinced him that the phenomenon of anaphylaxis was due to a reaction of the precipitin type produced in the living cell itself, whereas excess of the antibody in the blood and body fluids, so that the reaction occurs outside the cells, protects the sensitive structures, showed that this conception elucidates the whole subject of anaphylaxis. Far from being the opposite of immunity, anaphylaxis should be regarded as a protective phenomenon. Anaphylaxis should be regarded as a stage of immunity in which the resisting mechanism is located in the cells. When invasion of the tissues by a foreign protein takes place by natural means, as by an infecting organism penetrating the skin or mucous membrane, the local reaction to cell-injury produces protection against further invasion. When, by the artificial method of the injection needle, the antigen is brought rapidly into contact with all the cells of the body the anaphylactic reaction is the result. Anaphylaxis is thus not only compatible with but may even be a factor in resistance to infection. Dr. DALE pointed out that the only important chemical difference between species lies in the composition of their proteins. Organisms resent the artificial introduction of a protein of molecular pattern alien to their own; this is fundamental, because incorporation of an alien protein cannot be conceived without vitiation of type. To resist this vitiation the cell will die for the individual, or, if all the cells are affected simultaneously, the individual itself has to die in order that the purity of the species may be maintained.

[1] THE LANCET, May 21st, p. 1090.

MEDICAL INSURANCE AGENCY.

AT a meeting of the Committee of Management, held at 429, Strand, on May 12th, the chairman, Dr. G. E. Haslip, presented a report on the working of the Medical Insurance Agency for the year 1920. Substantial progress had, he said, been made in all classes of insurances. A gratifying feature was the large increase in life business. The special booklet prepared last May and circulated to non-members of the British Medical Association had brought in good business, many life, motor-car, and other policies being negotiated, on which the commissions earned by the Agency from this source alone amounted to over £250, practically the whole of the cost of printing and circulating the booklet being borne by the companies. The scope of the Agency is being extended and policies have been negotiated for medical men resident in British Guiana, India, and Mesopotamia. During the year 107 policies in all were taken out, the sums assured under them representing £99,138. A total of £1453 was returned to those insured through the Agency by way of rebates, or £493 more than in 1919. After allowing for rebates and agency expenses the surplus carried to the Medical Benevolent Account amounted to £1959. On this favourable financial situation the committee resolved to make grants of £315 each to the Royal Medical Benevolent Fund, the Royal Medical Benevolent Fund Guild, and the Epsom College Benevolent Fund. Mr. W. E. Warne, the retiring agent and secretary of the Agency, was thanked for his services, and Mr. P. N. Adamthwaite was appointed in his stead.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR.—The report of this institution for the year ending December, 1920, was presented to the annual meeting of governors on March 17th, and has just been printed. The number of patients under treatment during the year was 700, as compared with 879 in the previous year, and the medical statement shows that 84 per cent. of the cases treated gained an average of 7 lb. in weight. The number of cases improved averaged from 80 to 90 per cent. according to the severity of the disease, and of 301 cases selected for treatment by graduated labour 231 were discharged fit for work. Subscriptions to the institution amounted to £1118 17s. 6d., or £375 in excess of any sum received in previous years. The annual expenditure per occupied bed was £177 12s. 3d., as compared with £147 2s. 8d. in 1919.

Annotations.

"Ne quid nimis."

TWO DEVELOPMENTAL ANOMALIES.

AMONG the interesting exhibits at a recent meeting of the Anatomical Society, held at St. Thomas's Hospital, were two which, while their embryological interest was probably unique, may be considered also to possess some import from clinical and pathological standpoints.

A Remarkable Vitelline Duct.—The first was a specimen of persistent vitelline duct continuous with the side of the appendix. It was removed by operation by Dr. P. T. Crymble, of Belfast, from an otherwise seemingly normal and healthy child. The vitello-intestinal duct has been seen and recorded as attached to various abnormal sites, but we believe this to be the first time it has been reported found arising in this way from the appendix. The duct normally loses its connexion with the gut about the fourth to fifth week of embryonic life and quickly disappears, but cases of Meckel's diverticulum, representing its persisting proximal end, are not of very rare occurrence. The cæcum and appendix are developed in the extra-abdominal loop of gut behind the site of attachment of the duct, so that the condition in the case under consideration could not be referred to want of growth of the intervening portion of the loop; it would almost seem as if the first conical cæcal outgrowth had arisen on the proximal side of the duct. There does not appear to be any insuperable reason why the area of continuity between duct and gut should not remain anywhere in that part of the intestine formed outside the abdomen, and in this case the microscopic examination negatived the explanation that the end of a separated duct might have contracted secondary attachments to the appendix lying near it in the umbilical sac. The fact that the conditions in this case, as in many of the other cases of a somewhat similar nature recorded, came under observation because the clinical state called for surgical activities, is an indication that the surgeon has some interest in the embryological conditions which underlie the occurrence of such rare abnormalities.

True Developmental Aphakia.—The other condition exhibited at this meeting was that of aphakia in an embryonic eye, reported by Miss I. C. Mann. Many authorities have doubted the occurrence of true absence of the lens apart from other gross abnormalities, and the very few clinical reports of cases claimed as coming under the definition are mainly unsatisfactory, or worse. There is no doubt, however, about the case we are now considering. The embryo, somewhat shrunk, had been placed developmentally in the "13 mm. stage" by Professor Frazer, to whose collection it belongs. The histological condition is not good, the result apparently of faulty preservation, but no other abnormalities were detected in it. There is total absence of the lens on each side, and nothing to suggest that there ever had been any lens formation. A minute depression of the deep layer of the surface ectoderm represents, possibly, the abortive effort to form a fovea. The eyeball is the same size as that of a normal 13 mm. embryo, but it has a persistent choroidal fissure, not involving the optic stalk; there is thus no indication of microphthalmos, but a possibility of coloboma if maturity had been reached. Normally there is ectodermal thickening at about 4 months, a definite fovea or pit about 5, and a closed vesicle at 7, while at 13 months the elongated cells of the definite lens are well shown, and the whole structure is in the optic cup, separated by a considerable interval from the surface layer. It has been known for several years, on experimental grounds, that the invagination of the optic cup is not due to the formation of the lens, and this case is an interesting demonstration of the fact by Nature herself. Miss Mann's report puts the occurrence of true congenital aphakia, want of development, among the list of undoubted possibilities in ætiological pathology of absence of lens in living patients, for there would seem to have been nothing in the embryo itself to interfere with its survival.

HOOKWORM INFECTION IN BRAZIL.

WE have on former occasions called attention in these columns to the admirable work which has been done, and is still being done, by the International Health Board of the Rockefeller Foundation, more especially in connexion with their world-wide campaign against hookworm disease. In THE LANCET of Jan. 29th of the present year we commented on a report of this International Health Board, which dealt with the prevalence of ankylostomiasis in Egypt, the Malaya Peninsula, and the Dutch East Indies. Another report has now been issued (No. 14 of the series of Monographs of the Rockefeller Institute for Medical Research) giving the results of the investigations of two American experts, Drs. S. T. Darling and W. G. Smillie, sent to inquire into the prevalence of hookworm infection in Brazil. Their work was carried out in 1919 and was primarily directed to ascertaining the degree of infection of the native Brazilians by this helminth, its incidence on various occupations, the influence of race, and the effects of immigration on the introduction from without of fresh infection into Brazil. Efforts were also made to discover a routine method of treatment for hookworms that could be safely applied on a large scale to groups of persons, on plantations, for example, without the necessity of immediate medical supervision. The prevailing kind of hookworm in Brazil is *Necator americanus*, but *Ankylostoma duodenale* was found in every district that was visited by Drs. Darling and Smillie. It is interesting to note that the infection by this latter worm, though slight, is increasing, especially in places which have a changing population and where there is much immigration. The degree of hookworm infection in Brazil varies directly with the proximity of the individual to excrementally polluted soil. It is a disease of the rural districts, and more than 99 per cent. of the rural population of Brazil above the age of 6 years are infected with hookworms. The average number of worms per case in highly-infected districts was 136, though in some instances it was as high as 200 per case. Various remedies were tried with the view of finding a safe method of treatment that could be applied by unskilled subordinate officers on the plantations. The two principal drugs that were tested were beta-naphthol and oil of chenopodium. As a result of experiments the opinion was formed that the standard treatment with 1½ c.cm. of oil of chenopodium, given in two equally divided doses, with an interval between them of two hours, and the repetition of this dosage, after an interval of 10 days, is the best treatment of the disease; it is superior to treatment by 6 grammes of beta-naphthol administered on three successive days, because of greater efficiency in the removal of hookworms and other parasites such as ascaris and of its less toxic effects. The oil of chenopodium is administered in freshly-prepared gelatin capsules; care is necessary in measuring the dose of chenopodium, and this should always be done by means of a pipette and in terms of cubic centimetres. The use of this remedy for children, it is stated, needs careful medical supervision. The following are the details given by Drs. Darling and Smillie of the procedure with the treatment of hookworm patients on plantations in Brazil. The patient receives a light supper but no urge, and on the following morning 1½ c.cm. of oil of enopodium is given, on a fasting stomach, in two ses, with an interval of two hours between them, followed about two hours later by a saline purge of magnesium sulphate in a glassful of water. When the bowels have acted the patient may take his breakfast. As has been said the treatment should be repeated 10 days later. This is generally sufficient to remove the worms; in severe cases, however, a third treatment may be necessary after a further interval, but more than three treatments need never be given. For patients who can be treated in hospital under medical supervision a modification of the above method is used, the patient getting a preliminary purge in the evening and next morning receiving 2 c.cm. of oil of chenopodium, followed by a second purge two hours later. This is reported to be slightly more efficient and gives rise to less discomfort than the first-mentioned method.

THE MECHANICS OF MICTURITION.

THE urinary bladder resembles the heart in being an enlargement of a muscular tube with fluid contents. An interesting comparison of the mechanical functions of the two organs is set forth by O. Schwarz[1] Just as in a cardiogram so in a micturition curve there are three phases: (1) The phase of getting up pressure; (2) the expulsion-time; and (3) the relaxation period. The first phase lasts until the opening of the sphincter, and during this time the bladder executes an isometric contraction. The expulsion-time begins with the opening of the sphincter and ends with its closure, and this phase represents an almost characteristic isotonic contraction. The relaxation period is introduced with the closure of the sphincter, the change of tension taking place under constant volume, the contraction again becomes isometric. In micturition as in systole of the ventricle there is an after-loaded contraction. In the heart the rise of intra-ventricular pressure in the phase of getting up pressure depends on (*a*) the filling of the ventricle (load), (*b*) the muscle tonus, and (*c*) the peripheral resistance (after-load). The same factors obtain in contraction of the bladder. In the bladder the period of getting up pressure depends on the muscle tonus and the fullness (load) of the viscus. The contractile capacity of the bladder can be altered by influencing one or other of the factors—the detrusor urinæ or the fullness of the bladder. The micturition reflex can be favoured by increasing the tonus—e.g., after injection of pilocarpine, or by increased fullness of the bladder. The occurrence of residual urine can, from this point of view, be regarded as a compensatory process; if the fullness of the bladder is greater, the necessary initial tension is more easily arrived at. Besides these analogies there are differences between the heart and the activity of the bladder. The resistance, the after-load, in the case of the heart is represented by the pressure in the circulation; in the bladder, however, by the tonus of the sphincter. The contraction of the heart is first isometric, but after the aortic valves are opened the systole is what is called auxotonic—that is, it contracts against an increasing resistance, as the arterial pressure rises. The intra-ventricular pressure overcomes the peripheral blood resistance purely mechanically, but in the bladder the opening of the sphincter is a reflex phenomenon—a physiological instead of a physical event. The author sets forth his theory of micturition somewhat as follows. The filling of the bladder discharges reflexly a certain detrusor tension. When this tension has reached a certain value, it on its part liberates a higher pre-micturition increase of pressure. The sphincter is opened reflexly (opening pressure), whereby after the beginning of micturition the pressure rises still higher (maximal pressure). These three reflexes associated with the emptying of the bladder have a causal relation one to the other. If all three reflexes act and are unimpeded or not inhibited, then there is automatic micturition.

---

[1] Wiener Arch. f. Klin. Med. 1920.

In voluntary emptying of the bladder the course of each one of the reflexes is inhibited by cerebral influences. The most important inhibition results in relaxation of the detrusor. If the stimulus is stronger than the inhibition there results an involuntary micturition and discharge of urine.

THE PHENOLIPOIDS.

IN THE LANCET of March 27th, 1920, we drew attention to these compounds of carbolic acid, which, according to their discoverer, possess both antibacterial and antitoxic properties. Dr. V. C. Piazza, of the University of Palermo,[1] has now made further researches on these bodies and has produced 13 different compounds of phenol with yolk of egg (lecithin) cholesterin cerebral substance and camphor. He has worked out their chemical relations and biological properties when injected into the veins or peritoneal cavity of rabbits. The most suitable of them for medical purposes are Phenolipoids H, J, and N, composed of phenol cholesterin and camphor, phenol and the ether soluble lipoid of egg yolk with camphor, and phenol and alcohol soluble lipoid of egg yolk with camphor, respectively. They present several characteristics in common, being at ordinary temperatures, mostly of semi-fluid consistence and soluble in ethylic ether, benzol, chloroform, xylol, olive and essential oils. Solutions in chloroform give an emerald-green colour reaction with concentrated sulphuric acid, changing to a more or less intense red. They are all stable compounds, and exhibit a parasitotropic action by inhibiting the development of bacteria after a certain period of contact, and an antitoxic action by neutralising typhoid anaphylotoxin and the toxins of tetanus and diphtheria. The clinical application of these compounds has been taken up by Dr. F. Aliquo,[2] who has made experiments on 46 rabbits by producing septicæmia with injections of virulent cultures of *Staphylococcus pyogenes aureus*, and then observing the action of the phenolipoids on the morbid process produced. The phenolipoid was administered subcutaneously and in some cases by intravenous injection either at the height of the infection, or simultaneously with the inoculation of the staphylococcus, or else as a preventive measure. These experiments were rigorously controlled and hæmocultures made from blood were taken direct from the heart; thus 9 of the rabbits were controls, and of the remaining 37 there were 14 deaths and 23 recoveries. From a purely clinical point of view Dr. V. Guercio[3] administered Phenolipoids H and N by subcutaneous or intramuscular injection in many cases of influenza with pulmonary complications, and claims that the results obtained were much superior to those of other methods and in severe and prolonged cases were not only brilliant, but unexpected. It appears to us that these new compounds deserve considerable further investigation, both from an experimental and clinical standpoint; apparently, in this country, they have failed to attract the attention they seem worthy of.

AN EXPERIMENT IN POOLING SURGICAL RECORDS.

IN the last issue of *Acta Chirurgica Scandinavica* (1921, Vol. LIII., Fasc. V.) there is an editorial notice which marks a departure from the familiar paths of medical journalism. The notice begins with reflections on the present state of affairs, which permits of much waste of good material. Valuable observations often fail to get further than the surgeon's note-book or case papers. He may realise that to publish an interesting case it is desirable for him to study the literature of the subject, and for this he may have no time. Or he may defer publication of an interesting case in the hope that a similar case may turn up; this hope may never be realised, and the oblivion to which the first case was temporarily condemned becomes permanent. There are also innumerable isolated observations over which it hardly seems worth while to rush into print, although when grouped with other observations they may be of incalculable importance. With a view to drawing on these hitherto unexplored sources of knowledge the editorial staff of *Acta* proposes to constitute itself as a clearing house for odds and ends of surgical information, and once a year to publish a résumé in which the names, addresses, and nationality of the authors of this information will be given. Their contributions will be sorted out into anatomical or clinical groups, and will be reproduced in extenso or edited so as to fit in with similar observations from other quarters. It is hoped that the result of these labours will be a concise as well as a comprehensive digest, and that authors will gain rather than lose by pooling their knowledge. This yearly digest is to be published in English and will be supervised by Gunnar Nyström, surgeon to the Sabbatsberg Hospital in Stockholm. All three Scandinavian countries, as well as Finland, are represented on the staff of *Acta*, and this notice is addressed to surgeons of all four countries. It will be interesting to follow the evolution of this scheme, which, if successful, will doubtless be copied in other countries. Obviously much depends on the tact and judgment with which this surgical pool is stirred, and the sponsors of the scheme are to be congratulated on securing the services of Dr. Nyström for a very delicate task.

OPERATION FOR STRANGULATED HERNIA IN THE AGED UNDER LOCAL ANÆSTHESIA.

Dr. Martin T. Field[1] has recently made a strong plea for local anæsthesia in operations for strangulated hernia in the aged, as it eliminates many of the dangers incurred under general anæsthesia. Statistics from the larger American hospitals show that the operative mortality incident to acute intestinal obstruction, excluding strangulated hernia, has not been greatly reduced in the last 10 or 15 years, while that of strangulated hernia has. This Dr. Field attributes to earlier diagnosis, less manipulation, and operation under local anæsthesia. The last condition is particularly suitable for local anæsthesia, as, unlike other forms of obstruction, there is no need to search for the point of obstruction and it is readily accessible. In cases of inguinal hernia Dr. Field infiltrates the skin and subcutaneous tissue along the line of incision with 0·5 per cent. of novocaine and then plunges the needle down until it overcomes the resistance of the external oblique aponeurosis. About ½ oz. of solution is deposited beneath this structure in the position of the ilio-inguinal nerve. A little is also injected in the region of the external ring. After waiting a few minutes the incision is carried down to the external oblique. This structure is carefully opened near the internal ring and the flaps raised, exposing the ilio-inguinal nerve which lies on the internal oblique muscle. The nerve, which controls nine-tenths of the sensation in this region, is at once blocked by injecting it. The aponeurosis is now cut down through the external ring and also above the internal ring, exposing the ilio-hypogastric nerve, which is also blocked. The only nerve which can then convey sensation is the genital branch of the genito-crural, which lies in the posterior part of the cord. It can be blocked later, or the same result can be attained by injecting the upper part of the cord, care being taken not to puncture a vein. No more novocaine is required, except a little to render the parietal peritoneum insensitive when tying the sac. The radical operation is then performed, with or without removal of the testicle. In old persons, especially with recurrent hernia, the removal of the testicle

---

Atti della R. Acad. delle Sc. Med. in Palermo, 1920.

[2] Annali di Clinica Medica, Anno x., Fasc. iv.

[3] Riv. Sanitaria Siciliana, Anno ix., 1921, No. 2.

[1] Boston Medical and Surgical Journal, April 21st.

helps to prevent recurrence. In femoral hernia there are so many branches of nerves from all sides that the infiltration method is necessary. Gimbernat's ligament is cut or stretched with a small retractor, and when the tissues about the neck of the sac are freed the hernia can generally be reduced. After injecting a little solution about the neck the sac is tied off and resected. It is allowed to retract within the abdominal cavity, and Poupart's ligament is sutured to the pectineus muscle and fascia, including in the bite of the needle all the tissues down to the pubic bone. The wound is closed without drainage. Dr. Field reports eight consecutive cases of strangulated hernia in patients of ages varying from 67 to 90 years which he operated on with success by this method. He is certain that he could not have obtained this result with general anæsthesia. In none of the cases was resection of the bowel performed, which Dr. Field thinks should not be done unless urgently needed, as statistics show that nearly all primary resections in old people are fatal. If the bowel is hopelessly damaged it is better to drain and repair later. In some of the cases in this series there was considerable doubt as to the viability of the bowel, but in all convalescence was uneventful.

DIRECT COLOUR PHOTOGRAPHY IN MEDICINE.

THE demonstration of coloured lantern-slides at the Section of Dermatology of the Royal Society of Medicine showed the possibilities of this new method for purposes of illustration and teaching. Uvachrome diapositive lantern-slides are made from the original films employed in a new process of natural colour-photography in which no screen is employed; the minutest details can thus be projected upon the sheet without the loss in accuracy caused by disintegration of the colours. The dyes used in the preparation of the films reproduce the original colours with remarkable accuracy. The process does not lend itself to mass production, but it is found to be of the greatest value for scientific purposes.

The slides are at present prepared by the Austrian State Institute of Photography, which keeps expert photographers at the disposal of the Viennese hospitals and clinics, so enabling accurate colour photographs to be made of cases of special interest. The negatives provide a record for the hospital archives, and furnish medical lecturers with the slides of individual subjects which they need. It is proposed to carry out the same work in England for the benefit of medical authorities in the hospitals and universities. If, as the makers claim, the films can be satisfactorily reproduced on paper, they should prove very valuable for use in text-books and in original articles on rare diseases.

THE DIAGNOSIS OF TUBERCULOSIS IN CHILDHOOD.

IN a paper read on April 12th at a meeting of the London Association of the Medical Women's Federation on the subject of Tuberculosis in Children of School Age, Dr. Jane Walker gave instructive figures and interesting comments thereon. In a report on these figures in THE LANCET of April 23rd a clerical slip occurred, and it should be noted that of the 807 children referred to 8·4 per cent. (not 62 per cent.) were sputum-positive. Even more important than her statistics was the broad and philosophical spirit in which she approached her subject. In science, as in religion, the best guarantee of fitness to advance is a broken and contrite spirit. Dr. Walker tempered her candid agnosticism with shrewd hints on how to emerge from this healthy but barren state. As her survey showed, the incidence of tuberculosis among school children has been variously estimated at 0·7 per cent. to 96 per cent. An intermediate calculation is that made by Sir Robert Philip, who considered that not less than per cent. of school children bear the stigmata of erculosis. We may to a certain extent whittle this glaring disparity by regarding the lowest figures as indicating actual disease, and the highest as referring only to infection without great morbid change. But such an arbitrary expedient for conciliating contradictory statistics is plausible only on the surface; it soothes too much and stimulates too little. If we accept the outside figure of 96 per cent. as being the measure of tubercle infection among school children at the age of 12, we are still as much in the dark as ever in forecasting the ultimate fate of these children. All we can say for certain is that the majority will not succumb to tuberculosis. Even for the remaining 4 per cent. who, at the age of 12, are, biologically speaking, "virgin soil" we can cast no accurate tuberculosis horoscope. The next generation will be better off in this respect, for in a few decades valuable information should be available as to the expectation of fatal tuberculosis for each person who has been periodically tuberculin-tested since infancy. Meanwhile it is the obvious duty of all concerned with the medical supervision of children to make and preserve careful tuberculin records, so that in due time we may clearly read into the tuberculin tests diagnostic, therapeutic, and prognostic knowledge which is at present withheld from us. Even now there are aids to diagnosis which can be interpreted with considerable clearness, and in emphasising the importance of the X rays, Dr. Walker consciously or unconsciously censured the many large institutions in this country which are satisfied to continue dispensing with this important weapon.

BENIGN GASTRIC ULCER IN SYPHILIS.

Dr. W. Frank Fowler,[1] of Rochester, New York, remarks that in spite of the publication of numerous papers on the various phases of gastric syphilis no case has hitherto been recorded of non-specific ulceration in the stomach of a syphilitic, although several writers such as Einhorn, Niles, Eusterman, and Morgan have indicated the possibility of this occurrence. The gross lesions of gastric syphilis have been classified by Eusterman into (1) gummata in various forms, (2) diffuse syphilitic infiltration. The degeneration of gummata gives rise to specific ulceration, the symptoms of which differ from those of benign ulcers, chiefly in the absence of relief of pain by food and alkalis, less periodicity, anacidity, vomiting with good appetite, excessive loss of weight, and improvement in the gastric function under specific treatment. Apart from operation the diagnosis usually rests on a past history of syphilis, the presence of signs of late syphilis, a positive Wassermann reaction, and the therapeutic test. On the other hand, it must be borne in mind that a negative Wassermann reaction does not exclude syphilis, and that a positive reaction does not prove that a gastric lesion is specific. The therapeutic test though usually reliable is not infallible, as antisyphilitic drugs sometimes favourably influence non-specific conditions. X ray evidence is not conclusive, as we may have close simulation of carcinoma. Even exploratory operation may not be decisive, and cases are on record where gastro-enterostomy has been performed for the relief of syphilitic gastric ulcer. Microscopical evidence consists in characteristic syphilitic obliterative endarteritis and perithelial lymphocytic infiltration with atrophy of the mucous membrane, and hypertrophy of the submucosa and muscularis. Dr. Fowler's case was that of a woman aged 26, who had been suffering from symptoms of gastric ulcer for eight years and presented evidence of secondary syphilis. The Wassermann reaction was 4 +, and she was given a course of specific treatment. No improvement, however, followed, and gastro-jejunostomy was performed with the result that relief was obtained for seven months. The symptoms then recurred and laparotomy was again performed. A large callous ulcer of the usual benign type was found on the posterior wall of the stomach adherent to the pancreas. The pyloric half of the stomach was removed, and the old opening in the jejunum was anastomosed to the gastric stump. Uncomplicated recovery took place.

EARLY DIAGNOSIS IN DIPHTHERIA.

THE importance of early diagnosis in diphtheria and of the administration of effective doses of antitoxin as soon as possible is generally recognised. It comes, therefore, as a surprise to find that Dr. Frederic Thomson, of the North-Eastern Hospital, Tottenham, in the interesting letter published in THE LANCET last week, has noticed that for the past two years many patients have been arriving at his hospital rather later in the disease than was formerly the rule and often without antitoxin treatment. He suggests that this delay in sending patients to the special hospital is largely due to practitioners waiting for the results of bacteriological examination, and he strongly deprecates this being done. He urges that antitoxin should be given without delay if the clinical evidence favours diphtheria. He points out that failure to find the bacillus in cultures taken early is not uncommon, that cultures taken on the first day even from cases of the several faucial diphtheria are frequently negative, also many of those from purely laryngeal cases. On the other hand, a positive result may be due to the case investigated being a diphtheria bacillus carrier. Dr. Thomson's letter is worthy of the special attention of our readers, since the advice he gives is of practical importance, and the point he raises in regard to the bacteriological evidence is one of great interest. There is a tendency in the minds of some practitioners to regard the evidence afforded by laboratory investigation as incontrovertible and infallible, whereas it should be assessed in the light of the other evidence and its indications placed in their true perspective. The importance of Dr. Thomson's suggestion is emphasised by his statement that the death-rate among his cases in 1919 and 1920 was higher than it had been for many years, while he is not prepared to admit that the type of the disease had been much more severe.

MATCH-BOX DERMATITIS.

THE substitution products employed in Germany during the war and still in use have given rise to a number of hitherto unknown skin diseases to which must now be added match-box dermatitis. This condition, of which Dr. Herbert Stranz,[1] of Breslau, has seen sixteen examples during the last six years, is most frequent in the male sex. His cases occurred exclusively in heavy smokers who were in the habit of carrying a match-box in their trouser pocket. In typical cases the eruption begins on the upper third of the front of the left thigh, occasionally on the right thigh or both thighs at once, as well as on the adjacent part of the hypogastrium and hips, and then attacks the backs of both hands and the face. Experiments made by Frei, in Jadassohn's clinic at Breslau, showed that the dermatitis was due to the presence of the sesquisulphide of phosphorus, which has been used as a substitution product on the striking surface of the match-boxes since the beginning of the war. The warmth of the body sets free the irritating substance in the form of a vapour which attacks the skin lying beneath the trouser pocket, and the backs of the hands and the face subsequently become affected. The clinical picture of match-box dermatitis varies with the extent and age of the lesions and the special sensitiveness of the individual. Occasionally only a slight circumscribed erythema is seen resembling erysipelas. But in many cases an exudation takes place with the formation of crusts. In one of Dr. Stranz's cases the œdema was very pronounced. In long-standing cases the condition resembles chronic lichen. Even in mild cases there is very severe itching and burning pain, and the patient suffers generally owing to loss of sleep. Unless the cause is recognised the condition is liable to last for years. Treatment consists in applying compresses of 1–2 per cent. boric or resorcin solution. Dr. Stranz has also obtained good results from the use of X rays owing to their anti-pruriginous action.

HOSPITAL PHYSICIAN AS SANITARIAN.

THE retirement of Dr. William Hunter from the active honorary staff of Charing Cross Hospital gave his colleagues and friends opportunity to express, not only their warm personal regard, but their ungrudging admiration for his services to his hospital and medical school, to medicine, and to the public health. The occasion was a complimentary dinner given at the Imperial Restaurant on Friday, May 20th, at which Mr. George Verity, chairman of Charing Cross Hospital, presided. Dr. Hunter's association with the hospital covers the period during which financial difficulties were met and overcome, and his term of office as dean initiated a similar period of prosperity in the medical school attached to the hospital. His work on oral sepsis established its importance as a forerunner of chronic ill-health, an association now generally recognised. Fortunately it has been given to many hospital physicians to combine fruitful clinical and experimental work with administrative achievement, but to Dr. Hunter's credit is a third exploit in a larger field, when within a few months he was instrumental in ridding the Serbian army in the field of typhus and relapsing fever, and this by means of simple appliances of universal application. The recent exhibit of sanitary appliances at the Royal Army Medical College (see page 1133), it may be noted, included a sack disinfector which carries the principles of Hunter's Serbian barrel into the home. Medicine is one and indivisible, and the equipment of a successful clinician, medical administrator, and sanitarian is not dissimilar in essentials.

URBAN VITAL STATISTICS.

(Week ended May 14th, 1921.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate population estimated at 18½ million persons, the annual rate of mortality, which had been 12·5, 12·5, and 12·1 in the three preceding weeks, was 12·5 per 1000. In London, with a population of 4½ million persons, the annual rate was 11·6, against 11·5 per 1000 in the previous week, while among the remaining towns the rates ranged from 4·7 in Dewsbury, 5·7 in Grimsby, and 5·9 in Walthamstow, to 20·0 in Oldham, 21·2 in Exeter, and 21·9 in Barnsley. The principal epidemic diseases caused 227 deaths, which corresponded to an annual rate of 0·6 per 1000, and comprised 71 from whooping-cough, 50 from diphtheria, 48 from infantile diarrhœa, 13 from measles, 11 from scarlet fever, and 1 from enteric fever. Measles caused a death-rate of 1·3 in Sunderland and in South Shields, and 1·4 in Barrow-in-Furness, and whooping-cough of 1·1 in Liverpool and in Oldham, and 1·5 in Burnley. There were 3238 cases of scarlet fever, 2281 of diphtheria, and 1 of small-pox under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 3195, 2313, and 1 respectively at the end of the previous week. During the week ended May 7th 6 cases of encephalitis lethargica were notified in the County of London, from Camberwell, Chelsea, Hammersmith, Southwark, Stepney, and Wandsworth respectively. The causes of 28 of the 4434 deaths in the 96 towns were uncertified, of which 10 were registered in Birmingham and 3 in Gateshead.

Scottish Towns.—In the 16 largest Scottish towns, with an aggregate population estimated at nearly 2½ million persons, the annual rate of mortality, which had been 14·6, 15·0 and 14·7 in the three preceding weeks, fell to 14·3 per 1000. The 339 deaths in Glasgow corresponded to an annual rate of 16·1 per 1000, and included 25 from whooping-cough, 3 from measles, 2 each from diphtheria and infantile diarrhœa, and 1 from scarlet fever. The 101 deaths in Edinburgh were equal to a rate of 11·8 per 1000, and included 3 each from whooping-cough and diphtheria, 2 from infantile diarrhœa, and 1 from measles.

Irish Towns.—The 137 deaths in Dublin corresponded to an annual rate of 16·9, or 1·8 per 1000 below that recorded in the previous week, and included 1 from infantile diarrhœa and 1 from diphtheria. The 121 deaths in Belfast were equal to a rate of 15·0 per 1000, and included 9 from whooping-cough, 2 from infantile diarrhœa, and 1 from diphtheria.

SOME EFFECTS OF ALTITUDE ON THE HUMAN BODY.

By A. REEVE HEBER, M.D., CH.B. BRISTOL.

SINCE the year 1800 a good deal of work has been done on testing the effects of altitude on the human body, and during the war the choice of men for the Flying Corps has made such work most important. The writer having lived for about six years at an altitude of 11,500 ft. in Leh, the capital of Ladak, one of the provinces of Kashmir, found himself able to test the chronic effects of residence in altitudes.

The country in which I worked is situated in the Himalayas, and is very cold during the winter and very hot during the summer, but both cold and heat are less felt on account of the extreme dryness of the atmosphere. During the summer the power of the sun is immense; an ordinary thermometer exposed to the sun on an ordinary day (30/7/20) at 12.15 P.M. registered 108° F. The report of the Meteorological Department of India gives the following temperatures for the year 1914:—

Mean temp. of year	37·5° F.
Mean maximum temp.	54·5° ,,
Departure from normal of year	0·9° ,,
Mean minimum	29·8° ,,
Departure from normal	0
Yearly mean of mean between max. and min.	42·2° ,,
Departure from normal of year	0·4° ,,
Mean daily range of temp.	24·7° ,,
Highest temp. observed during year	86·3° ,,
Lowest temp. observed during year	1·2° ,,
Absolute range during year	87·5° ,,
Mean monthly absolute range	42·4° ,,

With regard to the extraordinary dryness, the Indian Meteorological Report for 1914 gives the following figures:—

Mean humidity of year	0·53
Departure from normal	0·1
Rainfall for year	3·84 inches
Normal rainfall for year	3·26 ,,

There is very little wind in the winter and the air is very calm, but during the spring we get what are called the "Spitlung," which, coming from the snow regions, are bitingly cold. The prevailing wind is from the south, and has a comparatively great average speed.

The barometric pressure is the most important factor in determining the effects of altitude on the human body. The figures for Leh for 1914 are as follows:—

Elevation of bar system above sea-level	11,503 ft.
Highest pressure recorded during year	19·984 in. Hg.
Lowest pressure recorded during year	19·340 in.
Absolute range during year	0·644 in.
Mean monthly range of pressure	0·579 in.

It will be noticed that in Leh the glass is fairly stable. The boiling-point is lowered proportionately, and for Leh is 183·6° F., a fact soon realised when trying to make a good cup of tea. By comparison with Major J. L. Birley's second Goulstonian lecture,* the proportion of oxygen at this altitude should work out at about 13 per cent., and shows its effects chiefly as one would expect, in the respiratory, circulatory, and nervous systems.

The people among whom I worked were mostly Ladakis, who are really Tibetans, but I was also able to test a fair number of Yarkandis, down-country Indians, and about four English men and women (two of each), all of whom were resident in Leh for longer or shorter periods. The religions of these various people were almost equally diverse, as they belonged to the Buddhist, Mahommedan, Hindu, Christian, and Sikh persuasions.

It is most difficult to arrive at merely an approximate figure for the population of Ladak as no census has been taken for many years. There would be about 8000 inhabitants in Leh and about 150,000 inhabitants in the whole of Ladak. The greater number of these are Buddhists, but about 300 are Mahomedans, which enumeration closely adheres to the Mahomedan custom of not counting their women. Most Ladakis are farmers, though in Leh itself one finds a few traders and a small number of artisans.

General Considerations.

During short stays in altitudes the European seems to be fairly healthy, but it seems to me that the "altitude of happiness" varies for each individual. I am quite comfortable at 11,000 ft., a good deal less so at 14,000 ft., but on going higher feel fitter again. In 1913 Sir Filippo de Filippi brought a scientific expedition to Leh. His second-in-command never felt well in Leh, but on getting higher was quite fit. This fact was also noticed by Barcroft, who says, "Why did I become acclimatised at once on Monte Rosa when I did not at Teneriffe? and, secondly, why did Douglas acclimatise at Teneriffe when I did not do so?" This fact is rather difficult to explain, for although acclimatisation may have a good deal to do with it, yet in the second instance quoted above there was ill-health, even after several weeks' time in Leh, during which acclimatisation should have taken place, yet immediately on going higher, when such adaptation had not been obtained, improvement occurred. Europeans living in Ladak are usually very fit physically, and even after prolonged residence would be quite healthy, if only their nervous systems were equal to the strain, but this is the weak link in the chain. It has also been noted that the longer the European stays in Leh the more he feels the cold.

The natives are generally very healthy, but when serious disease of any kind does supervene collapse and death occur very rapidly and suddenly. They are not quite as long-lived as the lower-living races. The infant mortality is appalling, and the writer found that of 848 children born 310 died, a mortality of over 36·5 per cent.; but this is due mainly to neglect and not primarily to altitude, for among the few European children who have lived in Leh the mortality is a good deal less. It is simply impossible to establish the cause of death, which is generally stated to be "fever." The heights of about 160 Ladaki men and women was measured, and it was found that they are on the whole shorter than English men and women of the same ages, but it takes the Ladaki about the same time to attain his full stature, and while the Englishwoman's height tends to decrease after the age of 22 years, her Ladaki sister steadily increases in height until she reaches her fortieth year.

Respiratory and Circulatory Systems.

The power of "holding one's breath" is seriously curtailed, and in 52 cases this was found to vary between 40 and 19·7 seconds, the former figure being for the writer himself, and the average for all working out at only 27 seconds. This is all the more surprising when Major Birley found that at an altitude of 10,000 ft. a man should be able to hold his breath for 71 seconds.[1] One wonders whether this is directly due to prolonged residence in altitudes. It was further found that the European who has lived for some time in Ladak, and the native born there, find breathing distinctly easier than those who have just arrived in the country. It is also interesting that the statement "all men are mouth-breathers above 12,000 ft." is not true of people who have spent some time in the heights. I have crossed the Kardong Pass, which is 17,400 ft., and, except during and immediately after exertion, breathed through the nose. This is due, no doubt, to the fact that the lungs themselves expand to meet the altered physical conditions. I heard that a former doctor in Leh had definitely stated that his chest had enlarged during his stay in the country. Dr. Kathleen Heber found that during her first two years there her thoracic outlet had expanded 2 in., although her actual body was thinner. The same kind of statement is made by almost every European who has lived there. During 1920 I accompanied a lady from Srinagar (5000 ft.) to Leh and took measurements of her chest just under the axillæ, immediately below the nipples, and at the thoracic outlet, and again five weeks later after a three weeks' stay in Leh (11,500 ft.) and found that during this time her chest had expanded ½ cm. in each position. Although one cannot base any conclusions on this one case, yet it does show the tendency. In this connexion it is of interest that the chests of the natives measured (over 150 cases) were on the average smaller than those of the Europeans. This expansion of the chest is evidently consequent on an expansion of the lungs, for in the 160 cases examined it was found that the area of superficial cardiac dullness is distinctly lessened—viz., the upper border is shifted down to the fourth intercostal space or even the fifth rib, its left border moves in to 2½ and 2 inches from midsternum, and although the right border is found at the left border of the sternum, yet even here there is a tendency to overlapping of the heart. In the examination of hearts in Ladak, it is striking that in so comparatively few cases the apex beat of the heart is seen, which would also be accounted for by increase of lung tissue. The liver, too, seems to be pushed down a little; in the greater number of cases examined the upper anterior border was found at about the sixth rib. The rate of respiration is increased, and for corresponding ages in England varied from a quarter to three and a quarter breaths per minute, whilst the proportion of respiration- to pulse-rate is a little higher than 1 : 4—i.e., the respiration-rate has increased slightly more than the pulse-rate.

---

* THE LANCET, 1920, i., 1205.

The fact that anoxæmia causes periodic breathing has long been known, and is found to exist even when Europeans have lived in the country for some years, especially when ascending the mountains. My little hill pony, which was born in Zankskar, the most highly situated province in Ladak, exhibits it when going up steep hills. The pulse-rate also tends to be a little higher than in England, varying from 2–12 beats per minute. Dr. Kathleen Heber noticed that her own pulse averaged ten beats quicker in Leh than in Srinagar, which is over 5000 ft. lower. It had often seemed to the writer that the pulse-rate increased much more rapidly with increase of the temperature than in England, and he therefore investigated his temperature charts, but found that for every rise in temperature of 1° he got on an average an increase in the pulse-rate of 7·2 beats per minute, which is about normal even for England.

In respect to blood pressure, tests made on about 200 patients gave the interesting result that between the ages of 22 and 65 years the average blood pressure is even lower (118·9 mm. Hg) than the minimum (120 mm. Hg) which is usually given for Englishmen. At other ages the figure is somewhat higher, but as these only represent about 15 per cent. of the subjects tested, they are not nearly so reliable as the figures for the ages 22–65 years. This fact harmonises well with the findings on airmen that prolonged flying in altitudes tended to lower blood pressure. The pulse pressures obtained in Leh showed a definite increase, and this was more marked in the women than the men, this increase being 8·6 higher for men, to 12 mm. Hg for women, as compared with those in England. This is chiefly due to a fall in diastolic pressure, and again agrees with conditions found in our airmen in France.

The heart itself is not enlarged upwards nor to the left, but there were quite a number of cases in which the heart had enlarged to the right (of the 160 cases tested 27 per cent. had enlarged to half an inch to the right of the right sternal border), which is not surprising. As the atmosphere contains less oxygen the heart has to pump more blood into the lungs, but the blood pressure being lower in Ladak the left heart does not need to enlarge in order to eject a larger blood stream. Red blood counts were done on over 50 people, consisting of Ladakis, Downcountry Indians, and five Europeans. The average blood count for all the men of these is 6,816,454 per c.mm., which is somewhat below the figure at which Major R. W. G. Hingston arrived in his investigations in the Pamirs. The Ladak figure is slightly smaller than his on account of the striking fact that the men born in the country had a lower count than the Downcountry Indians and Europeans. Among the women the same is true, and in both male and female there were over a million more red cells per c.mm. than in those born in the country. We can state, therefore, that altitude raises the blood count, but to a lesser degree in those born in the country than those from lower altitudes. Leucocyte and differential leucocyte counts did not show much variation from the normal for England. When, however, the investigations on the hæmoglobin percentage were begun, it was thought that the results would prove a good deal higher than in England, and it was all the more surprising to find that the percentage was well below 100. This was true of all sorts and conditions of men and women in the country, and, whether born there or in the lowlands, the figures approximated very nearly to 90 per cent., the former being just over and the latter just under. It is difficult to account for this, and it may be suggested that a *prolonged* stay in altitudes tends to destroy hæmoglobin.

The human body, therefore, seems to respond to decreased oxygen-tension in the atmospheric air of altitudes by a small increase in the rate of both respiration and pulse, whilst the lungs and, in consequence, the chest, expand; further, the heart tends to enlarge to the right, the work of the left ventricle being made lighter by a decreased blood pressure. An increase in the oxygen-carrying powers of the blood is made possible by an increase in red blood corpuscles, which is greater in the downcountry man than in the native inhabitant. Finally, the first response to a rapidly decreasing oxygen pressure consists in periodic breathing.

Nervous System.

The European on first arriving in Ladak feels most extraordinarily fit—he sleeps well, he eats well, and feels himself equal to almost anything. The journey itself, which is accomplished in 16 short stages, either on horseback or on foot, tends to cause this exhilaration. But, sooner or later, it gives place to a terrible weariness of the brain, sleep becomes difficult to obtain, interest in food is lost, and even a short day's work produces great weariness, especially if that work is mental, and in spite of the fact that the rest of the system is in good order. But even when this condition has been reached, there is still a short period during the morning in which the brain is keenly active, and during which work is a real pleasure. This deterioration is, however, not as serious as that in one's temper and all the other subjective functions of the brain. It is astonishing how even the most decisive man slowly and insidiously loses the power of decision and becomes unwilling to bear responsibility. Things are not improved by the fact that the memory suffers also, and sometimes it almost seems as if morals were affected too. Peripherally, altitude showed its effect on the nervous system of Europeans by causing numbness and tingling of the limbs much more rapidly than at home.

Alimentary System.

That the human body needs more sugar and butter when in altitudes is a well-established fact, and even the native needs and obtains these by drinking endless butter tea and eating cereals. All Europeans suffer from the most appalling intestinal flatulence which it is difficult to explain, unless the decreased oxygen pressure stops the intestines from breaking up the foodstuffs into their end-products. One of the commonest of native maladies is sthenic dyspepsia, which must in great part be due to the fact that the boiling-point of water (183·6° F.) is insufficient properly to break down the starch granules.

Reproductive System and Special Organs.

The European birth-rate does not seem to be much affected. In passing, the writer would like to remark upon the rapidity with which delivery occurred. He had to conduct three confinements of Englishwomen up there, and found that the two primiparæ took three and a quarter and four hours, whilst one multipara took five hours. The native women marry early in life, the average age in 730 women being 14·1 years. The Ladaki birth-rate is extremely low; thus, 828 women between them only had 848 children. This is, in the author's opinion, not primarily due to altitude, but to syphilis. One would think that early marriage would lead to early menstruation, but, as a matter of fact, the average age at which 799 girls began to menstruate was 15 years, whilst with 195 women the menopause set in at 39·2 years, thus greatly shortening the bearing age of Ladaki women.

The Ladaki is, on the whole, very hairless, although actual alopecia is practically unknown. On account of the extreme dryness of the air, the skin desiccates badly and cracks, especially during the winter months. The hair becomes straight and lustreless and tremendously electrical. Eczema and chilblains, on the other hand, are very rare.

Notes on the Incidence of Disease.

Although "rheumaticky" pains are very abundant, yet true rheumatism or rheumatic fever is practically unknown. Again, coughs and colds have to be treated almost continually, and yet accute lung disease is comparatively rare, whilst tuberculosis hardly ever occurs. This can be accounted for by the fact that the air is so dry and free from micro-organisms. The manifestations of syphilis are peculiar, for, whilst the first stage is common, and also the skin manifestations of the second, it does not go further, and the later secondary and tertiary symptoms do not occur. Since the writer first went to Leh he has never seen a case of gumma there. One wonders whether the lowered blood pressure has anything to do with this. It was noticed that almost always those who registered merely relatively high pressures had suffered from syphilis. Furthermore, the parasyphilitic manifestations practically never occur. Similarly one sees a good deal of gonorrhœa, but strictures do not often result. In Kashmir, osteomalacia is very common, but in Ladak it does not occur.

Conclusions.

1. High altitude makes for health in both native and European, until in the latter the nervous system begins to break down. 2. The most serious effects of a long stay in altitudes are felt by the nervous system, and correspond with the acute effects observed in airmen. 3. Altitude has a tendency to enlarge the right but not the left side of the heart. 4. Altitude decreases the blood pressure, but increases the pulse pressure. 5. In altitudes the thorax expands and the lung tissue increases. Breathing is somewhat accelerated, whilst the power of holding one's breath is much curtailed. 6. In altitudes an increase of red blood corpuscles occurs, but this is more marked in those who have come from lower altitudes than in the indigenous population. The white blood count and the differential blood count remain much the same as in England. 7. Prolonged residence in altitudes does not increase, but rather decreases, the hæmoglobin percentage. 8. In Leh human fertility is decreased, whilst menstruation begins later and ends earlier.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Government Grants and the Health Services.

LAST summer, in view of the refusal of many local authorities in Ireland to strike rates for the purpose of meeting claims made on account of malicious injuries, the Government obtained power from Parliament to withhold Government grants ordinarily payable to local authorities, and to devote the funds thus held to meeting the claims for malicious injuries. At the same time many of the local authorities had debarred themselves from receiving grants by refusing to submit their books to audit by the Local Government Board. It was hoped that if they consented to the audit the grants would be forthcoming, and only last month the Vice-President of the Local Government Board assured a medical deputation that, so far as he knew, the refusal of audit was the only obstacle in the way of local bodies receiving their grants. Last autumn both the Irish Public Health Council and the delegates' meeting of the medical profession had put forward the suggestion to the Government that in any dispute which might arise with local authorities the health services should be immune and that grants ordinarily devoted to care of health should not be diverted to other purposes. The suggestion was treated with scanty consideration by the Chief Secretary, and last week the Government carried its threat into effect. By an Order made under the Restoration of Order in Ireland Act, it is directed that "with a view to making provision for the immediate payment of amounts recovered by decrees" against certain local authorities, no payment is to be made to these local authorities out of the Local Taxation (Ireland) Account, or out of any Parliamentary grant, or out of any fund administered by any Government department or public body. The names of over 250 local authorities of various classes are included in the Order.

This Order makes it clear that the funds are no longer merely held up pending an audit, but that they are to be definitely diverted to other than their customary purposes. The position as regards many of the health services becomes at once precarious. Out of the Local Taxation Account comes a State subvention toward the salaries of Poor-law officers including dispensary doctors. The subvention was originally supposed to pay half the salaries of the dispensary doctors, but as the Local Taxation Account has dwindled, and the salaries have increased, of recent years it only paid about one-fifth. The deprivation of even a fifth of his salary is, however, a serious blow to an already ill-paid doctor, who is entirely blameless as regards the genesis of the present state of disorder. It will be interesting to see whether, now that the Government has repudiated any responsibility for the payment of Poor-law officials over the greater part of the country, the Local Government Board will continue to attempt to exercise control over their performance of duty. Up to the present it has, regardless of the personal danger to which obedience would expose a dispensary doctor, continued to press him to make the usual formal returns to the Board.

The National Relief Fund and Irish Hospitals.

Out of the residue of the National Relief Fund granted to hospitals in the United Kingdom, £63,000 have been allotted to Ireland. Its distribution was in the hands of an influential committee of eight, presided over by the Rt. Hon. the Master of the Rolls. After deliberation the committee decided to adopt as a principle of distribution the relative number of "free beds" maintained by the several hospitals. The principle appears fair, but there must be considerable difficulty nowadays in defining a "free bed," since all patients are expected, as far as they are able, to contribute to the cost of their maintenance.

Dublin University Election.

The nomination of candidates to represent Dublin University in the Parliament of Southern Ireland took place on May 13th, and, four candidates only being nominated, they were declared elected. They are Mr. E. H. Alton, a Fellow of Trinity College and a classical scholar of distinction; Sir James Craig, King's Professor of the Practice of Medicine and President of the Royal College of Physicians; Mr. G. FitzGibbon, K.C., of the Irish Bar; and Mr. W. E. Thrift, a Fellow of the College and Professor of Natural and Experimental Philosophy. These four gentlemen had been requested by the teaching staff of the College and University to permit themselves to be nominated and electors will probably feel grateful to them for their willingness to serve their university in a difficult position. At the same time, electors are likely to hope that in future the teaching staff will not by any collective action attempt to influence the freedom of choice of the constituency.

Students at Irish Universities.

A Blue-book issued last week gives some information as to the number of students attending the National and Belfast Universities. The total number of students is 3130, distributed as follows: Belfast, 995; Cork, 608; Dublin, 1268; and Galway, 250. Of this total more than half—1752—are studying medicine or dentistry.

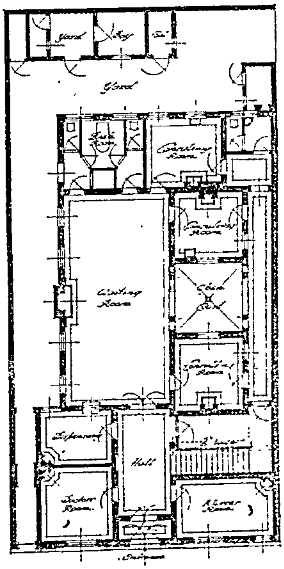
THE JOHANNESBURG SCHOOL CLINIC.

SINCE the inception of medical inspection of schools in the Transvaal in April, 1914, the necessity for an up-to-date school clinic for the largest urban area in the Province has been recognised by the Education Department. Sanction for the establishment of such a clinic was given early in 1915, but the interruption caused by war conditions and the excessive increase in the cost of building material, added to the fact that it was exceedingly difficult to obtain a satisfactory central site, necessitated the postponement of the original scheme. In 1918, however, a suitable site was obtained, within easy access of the schools and yet centrally situate, and plans were drawn for the building by Mr. Cleland, of the Public Works Department. Owing to the limitations of the site—100 by 50 feet only—the design had to be carefully considered in order to obtain the maximum working accommodation and amount of light and air. The clinic is claimed to be the finest of its kind in existence, and is probably the only one in Africa. The building, now completed, is a double-story block, of brick and reinforced concrete, with stone facings and a simple but dignified Georgian façade facing Jepe-street. The roof is of tiles, with square tiled chimneys at both ends; the flooring in all consulting- and work-rooms is of magnesite composition; in the corridors and hall it is of tiles, and the operating room has a floor of cement. The inside walls and ceilings are painted throughout with non-absorbent porcelain white, and the building is fireproof.

On the ground floor a small entrance porch gives access to a lobby which opens into the large waiting-room, which will also be used as a lecture and demonstration room. On the right of the entrance lobby are a nurses' common room (also to be used as a work-room), a fireproof record room, and the open staircase leading to the first floor. On the left are a doctors' sitting-room and a small dispensary. On the right of the waiting-room are three large consulting-rooms, each with a door opening on to the outside corridor, so as to give separate entrance and exit to patients. At the end of the waiting-room are lavatories and bathroom for patients and a private lavatory for the staff. Separate from the main building, in the small yard behind the block, are the native servants' quarters, with bed- and bathroom, the store room, coal shed and boiler room. On the first floor are large and exceedingly well-lighted operating rooms. one for the dental inspectors and the other for nose and throat operations. Between them is a small anæsthetist's room. Next to the main operating room is the eye room, which is flanked by a small linen room. A main corridor, terminated at the north end by a safety staircase, runs the length of this floor. On its right are two consulting-rooms, a kitchen, scullery and larder; on the left are a nurses' bedroom, and a small four-bedded ward for emergency cases, with bathroom and lavatory accommodation. The attached plan shows the general design of the building.

As the latter is flanked on the right by a three-storied block of residential flats, which cuts off much of the light, it was somewhat difficult to obtain adequate lighting and ventilation in the large waiting-room. The difficulty has been largely overcome by converting half of the available space on the right, between the two consulting-rooms, into an open porch. Ample window space has been provided in all rooms, the austral type of window being used, and additional light has been obtained by whitening all walls. The building is heated by open fireplaces in all rooms, but provision is also made for central heating if necessary. Furniture for the clinic is being made locally, and as teakwood has been exclusively used in the building, all wooden furniture will be of teak. Equipment has been ordered from Europe, and the Education Department is indebted to Dr. J. A. H. Brincker, of the Public Health Department of the London County Council, and to Mr. N. Bishop Harman and Mr. G. F. C. Wallis for help in selecting such equipment.

It is intended that the clinic shall be the staff headquarters of the school medical inspection service, and, as such, a central bureau for inspection and treatment. Dr. Anne F. Cleaver, assistant medical inspector, will be in charge of the clinic, and Nurse Hassall, assisted by 10 school nurses, will have charge of the nursing arrangements. A psychological clinic has been arranged for under the direction of Dr. J. M. Moll, the departmental psychiatrist, and other branches of clinic work will be a maternity department (prenatal clinic), a baby clinic, and a department for advising leavers and dealing with physically defective children. The treatment clinic will, in the terms of the arrangement made with the profession in 1915, be staffed by a panel selected by the practitioners on the Rand, the dentists selecting a similar panel. Treatment will be given free to all necessitous patients for defects of the eyes, teeth, nose and throat, and for minor ailments, practitioners being paid a nominal honorarium calculated on the basis of one guinea per hour of work. These arrangements are, however, subject to modification if the profession prefers that part-timers—as is at present the case—should be employed. The clinic will be open during vacations as well as during term, and it is hoped to make it a propaganda centre for social and public hygiene. For that purpose the waiting-room has been specially fitted up to enable the kinematograph to be used for lectures.



Johannesburg School Clinic: Ground-floor plan.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE opening of the summer session of the General Medical Council took place on May 24th, under the presidency of Sir Donald MacAlister.

The President's Address.

Sir DONALD MACALISTER commenced his address by referring to the deaths since the last session of two former members of the Council, Sir Frederick Taylor and Dr. R. J. Pye-Smith, the lives of both having been shortened by the sorrows and labours of the great war. He continued:—

Medical Reciprocity.—Through the Privy Council we have been in correspondence with certain foreign countries and dominions of the Crown on this subject. *Belgium*, which, during the war, granted to British practitioners the privilege of practising within its territories, was by Order in Council accorded corresponding privileges under Part II. of the Medical Act, 1886. Its medical graduates were accordingly made registrable in the British Foreign List, and some 101 were duly registered. The Belgian Government has now decided to reinstate its former medical regulations, which require our practitioners to obtain a Belgian qualification as a condition of practice. The conditions of reciprocity being therefore no longer maintained, His Majesty in Council has issued an Order revoking the application of Part II. to Belgium, and Belgian practitioners will in future be registrable only in respect of British qualifications. Those already registered will, however, retain their status in this country.

In *Spain*, the law has hitherto provided that individual foreign practitioners may, under certain conditions, obtain special permission to practise in that country. A change in the law is, however, in contemplation, and the British Ambassador has suggested that His Majesty's Government may see its way to granting reciprocity. The Executive Committee has requested that inquiries may be made as to the privileges which would be granted in Spain to practitioners registered in the United Kingdom, and as to the course of study and examinations prescribed for obtaining medical degrees and diplomas in Spain. We await the result with interest.

The *Union of South Africa*, which admits to its Medical Register practitioners registered in the United Kingdom, has within the last few years made much progress in developing its own system of medical education. Its universities have obtained power to confer degrees in medicine and surgery, and the Union is desirous that these degrees should, in due course, be recognised as registrable qualifications at home. The Executive Committee, to which the Council has delegated the supervision of such matters, has had no difficulty in advising the Lord President that Part II. of the Medical Act may properly be applied to South Africa, and it is probable that before long the necessary Order in Council will be issued. The Council will then be free to recognise South African medical degrees which fulfil the prescribed conditions.

For many years the medical diplomas of the *Indian Universities* have been recognised by the Council as conferring a registrable qualification to practise medicine, surgery, and midwifery in this country. Recent inquiries by the Executive Committee have, however, caused the Committee to raise the question of their present sufficiency in respect of midwifery. The information received from India has satisfied the Committee that in most, if not all, of the Indian Universities the prescribed courses of study and examinations in this important branch do not now furnish (in the words of the Medical Act, 1886) "a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice" of midwifery in the United Kingdom. The Committee has communicated its opinion to the Indian Universities, and intimated that unless within a year the standard of their requirements in midwifery is raised to a satisfactory level, recognition must be discontinued. The Council is charged under the Act with ascertaining, not the sufficiency of Indian qualifications for the needs of practice in India, but their sufficiency as conferring a registrable title to practise all three branches of the profession in this and other non-Indian parts of the Empire.

Work of Special Committees.

The Pharmacopœia Committee has had under consideration the Draft Regulations proposed by the Home Office for giving effect to the recent Dangerous Drugs Act. The Committee pointed out to the authorities various particulars, suggested by its members and by other members of the Council, in which amendment of the Draft was necessary in the public interest. The Chairman and Secretary, on behalf of the Committee, have had interviews with the officials concerned, and have by request given information on the subject to a special committee set up by the Home Secretary for the purpose of considering the numerous amendments to the Draft Regulations that had been proposed by medical and pharmaceutical bodies. It is understood that a detailed revision of the original text has been undertaken by the Home Office, with a view to removing, so far as the Act permits, the objections urged against the Draft. We have not yet received copies of the Regulations as amended, but we understand that effect will be given to our representations.

The Departmental Committee, appointed by the Ministry of Health to consider and advise upon the administrative measures to be taken for the control of the quality of certain therapeutic substances, such as serums, vaccines, salvarsan, &c., which cannot be tested by direct chemical means, has issued its Report. The recommendations give effect, in what appears to be a satisfactory manner, to the wishes of the Council, as expressed in a communication made to the Lord President in 1909. They will be considered in detail by the Pharmacopœia Committee, and reported on by the Council at this Session.

The Dental Committee also has been active during the recess in considering and advising on the successive drafts of the Dentists Bill, during the course of its preparation by the Ministry of Health. As it was made abundantly clear that the Bill would have little prospect of passing into law unless its provisions were generally agreed to beforehand by the various bodies concerned, a number of conferences have taken place at which the views of the Council, and those of representative members of the dental profession, were discussed with the officers of the Ministry. The Bill is now before Parliament, and has been read a second time in the House of Commons. While it embodies many of the points on which the Council has from time to time laid stress, it contains one or two that have not yet been considered by the Dental Committee or endorsed by the Council. On these it is possible that the Council may have further instructions to give to its representatives. But the Bill makes so great a step towards the removal of the dangerous abuses revealed by the Departmental Committee's Report that, though we may regret its imperfections, we may be prepared to welcome it as an earnest of wider reforms. I may mention that, at the instance of the Lord President, a clause has been introduced to give effect to your resolution of Nov. 27th, 1917, whereby three additional members of the Council, who are registered graduates or licentiates in dental surgery, and members of the new Dental Board, are to coöperate with the Council when dealing with dental matters. The additional or dental members are to be appointed by the Privy Council.

Finance and Registration.

Sir Donald MacAlister, after regretting that no progress had been made in Parliament with the Bill for simplifying, with a view to economy, the procedure at the election of Direct Representatives, briefly reviewed the finances of the Council for the year 1920. These he showed to be satisfactory. There is an aggregate surplus of income over expenditure and the expenses of the regular inspections have been met out of reserve. A general increase in receipts for registration accounts for this position. He continued:—

The registration of medical students, which in 1919 rose to 3120, in 1920 fell to the more manageable number of 2531; but this number is still higher than in any year prior to 1919. In my opinion, it would be in the interest of sound professional education were the numbers still further reduced. They impose a severer strain, educational and financial, on the schools and hospitals than the necessary recruitment of the profession demands, and in present circumstances the teaching institutions are less able to meet the strain. To raise the educational standard for admission, and to increase the fees for professional tuition, would thus seem, from all points of view, to be prudent and justifiable.

In respect of dentistry, a profession which still needs a large accession of fully trained recruits, the registrations in the Dentists Register number 217, as compared with 128 in the year before. They still fall short of the annual number before the war. New dental students, however, number 560. This, though somewhat less than in 1919, is (except for that year), the highest entry yet recorded. The small addition to the ranks of qualified dentists accounts, no doubt, for the unfavourable position of the Dental Fund. Last year it showed a deficit of £517. Should the Dentists Bill become law a new position will be created, and comparison with the present statistics will no longer be practicable. It is for this reason that I have ventured to bring to your notice the figures relating to what may be the final stage of the régime which has lasted since 1878. The finances of the Dental Board will have other resources to draw upon and other charges to reckon with under the new conditions.

The Medical Curriculum.

The procedure which you authorised in November for the investigation of the medical curriculum has been duly carried into operation under the direction of the Education Committee. In connexion with each Branch Council, four subcommittees have been set up, including many men of eminence in the sciences bearing on medicine and in its practice. These have readily lent their valuable aid to the Council's inquiry, and our thanks are due to them for their helpful coöperation. A number of preliminary reports and memoranda on different branches of the subject have been prepared and circulated to members. Before long joint meetings and conferences will be arranged for the coördination of these proposals, with a view to the elaboration of considered conclusions and recommendations for presentation to the Education Committee and ultimately to the Council.

The President said that the reports of the inspectors and visitors of the qualifying examination in the United Kingdom were practically ready for consideration by the Examination Committee, and he took the opportunity of acknowledging gratefully, for the Council and himself, the valuable services which had been rendered. In this expression he particularly included the name of Dr. Bruce Low, who has inspected the Public Health examinations. This task is complete and some of the results of the inspection will be available at once for the revision of the curriculum. Sir Donald MacAlister closed his address with the welcome information that the disciplinary cases would be few and simple.

Obituary.

SIR ROBERT WILLIAM JACKSON, L.R.C.P., F.R.C.S. IREL., C.B.,

DEPUTY SURGEON-GENERAL (RETD.).

Deputy Surgeon-General Sir Robert William Jackson, whose death at the advanced age of 91 was briefly announced in our Service columns last week, was probably the oldest medical man in Ireland. He was born in 1826 and qualified for the medical profession in 1851 with the licentiateship of the Royal College of Surgeons in Ireland, and three years later obtained his first commission in the Army. In the Crimea, whither he was immediately sent, he served throughout the whole of the campaign, and was present at the siege and fall of Sevastopol, obtaining the medal with clasp and the Turkish medal. Later he went to India during the Mutiny, where he assisted at the relief of Lucknow and was present at the battle of Cawnpore. In the operations during the Ashanti War, 1873–74, he served with distinction and took part in the capture of Coomassie. For his services he was mentioned in dispatches, received the medal with clasp, and was awarded the C.B. He was also mentioned in dispatches during the South African War of 1879, and in 1882, soon after reaching the rank of Brigade Surgeon, he joined the Egyptian Expedition and was present at the battle of Tel-el-Kebir. He was again mentioned in dispatches, received the medal with clasp, the bronze star, and the third class of the Medjidie. He was knighted on retirement after nearly thirty years of active service with the rank of Deputy Surgeon-General.

After his retirement Surgeon-General Sir Robert Jackson took up his residence in his native country and occupied himself with religious, social, and municipal activities. He was a warm supporter of the Young Men's Christian Association, and a promoter of all efforts in behalf of the poor and suffering. Sir Robert Jackson was twice married and of his four children, three sons and one daughter, a son was drowned some twenty years ago through the foundering of a ship on which he was serving as surgeon. Notwithstanding his age, Sir Robert Jackson was in full possession of his faculties when he died, and he will be greatly missed by his many friends and colleagues who were attracted by his modest and charming personality.

Correspondence.

"Audi alteram partem."

THE ÆTIOLOGY OF PSEUDO-COXALGIA.

To the Editor of THE LANCET.

SIR,—In his letter in THE LANCET of Feb. 19th Sir Henry J. Gauvain says: "Sundt and Legg both consider that trauma is the cause and that the condition is not due to infection." This, as far as I am concerned, is a misunderstanding. In my work entitled "Undersoekelser over Malum Coxæ Calvé-Legg-Perthes,"[1] I have insisted that the cause of this disease is not one but several. First among the causal factors comes *trauma*. In 10 of my 75 cases—i.e., in 53·3 per cent.—there was a history of trauma, in most cases acting directly on the hip, a shorter or longer time before the appearance of the first symptoms. Frequently these appeared immediately after the trauma.

Next to trauma *infection*, principally the so-called *rheumatic* infection, apparently plays a part. Cases of mal. c. C.-L.-P. have been recorded, in which the disease has developed directly or some time after acute polyarthritis (Brandes, Taylor and Frieder, Flemming-Moeller, Elmslie), five cases in all, to which may be added my two Cases (11 and 27). In my first case, as in Elmslie's, there was chorea minor, as well as acute polyarthritis. In another case of mine (case 32) "tic convulsif" appeared when the patient grew up. In other and rarer cases a C.-L.-P. apparently can at once or later follow acute osteomyelitis of the hip. Such a case was described by Perthes,[2] and probably one described by Preiser,[3] which appeared as a result of an acute "Säuglingsarthritis" of the hip. Some cases may result from a chronic infection with weakened virus, as Borchard and Eden suppose in the case of arthritis deformans.

Syphilis.—In nine recorded cases Wassermann's reaction was carried out and was always negative. The same was the case with 30 of my patients. The only exception was a patient (Case 22) who, however, never presented any symptom of syphilis. Wassermann's reaction was negative in the mother.

Tuberculosis.—All writers seem now to agree that the disease has nothing to do with tuberculosis. In 59 of my cases, in whom v. Pirquet's reaction was carried out, it has been positive in 18 cases, negative in 41—i.e., v. Pirquet's reaction was negative in 69·5 per cent. of my cases.

Of particular interest is the case of a girl, 9 years old, who developed slight diphtheria and was injected with serum on the outside of the left hip. Fourteen days afterwards she developed a serum-exanthem, with fever, delirium, swelling, and excessive sensitiveness in the various joints, especially those of the left leg. The fever continued for three days; the swelling of the joints did not vanish till eight days afterwards. When she got about again she could not move or lift her left leg on account of pain in the hip, in which typical mal. c. C.-L.-P. developed.

Rickets.—Calvé[4] decidedly associated pseudo-coxalgia with rickets. This view is also shared by Guye and Soederlund, whilst Perthes mentions that rickets in none of his cases could be considered the cause of the disease. Among 94 published cases, including my own, there was a history of rickets only in 32 cases—i.e., in 34 per cent. Among 120 scrofulo-tuberculous children at the Coast Hospital at Fredriksvern I found one or more signs of latent rickets in 36·7 per cent. If rickets was a frequent cause of mal. c. C.-L.-P. one would expect to find it coupled with the typical form of the rachitic coxa vara. This is, however, not the fact. In my material there is only one such case (Case 65), a girl, who in infancy had been medically treated for rickets. When she was 8½ years old there was a coxa vara on both sides, combined on the left side with mal. c. C.-L.-P. The patient had never limped nor shown any symptoms till after a trauma one year earlier. Immediately afterwards she had begun limping and complaining of pain in the left knee.

[3] Zeitschr. f. orth. Chir. Bd. xxi.

[4] Revue de Chirurgie, 1910.

Mal. c. C.-L.-P. can appear in a previously completely normal joint, as Sinding-Larsen, among others, has maintained,[5] and as one may also find examples of in my casuistic.

Frommé's hypothesis that "Spätrachit" is the cause of the disease is not generally applicable. This does not, however, exclude the disease being in some cases an expression of "tardive rachit." This, I think, to be the case with two patients of mine, described in my work (Cases 22 and 66), as well as with two later cases. All these four patients were boys whose disease had attacked both sides. All had suffered from rickets which had put its stamp on their entire habitus.

I suppose the chances are that in all four cases the cause of the disease was founded on a rachitic basis. This I think to be the case with three other bilateral cases examined by me (Cases 18, 47, 54). Taken all in all, I suppose that bilateral disease developing either spontaneously or after a trauma in patients with a history of rickets is to be considered as determined by rickets, and when the disease does not appear till four years afterwards, it is to be considered as a "tardive rachit."

Calot has lately, on a basis of 150 observations,[6] denied the existence of any mal. c. C.-L.-P. in saying categorically, "La maladie de Perthes (ou Legg) n'existe pas. Les containes des cases cités sont autant de subluxation congenitales larvées et meconnuées." The very fact that the disease as mentioned mostly appears in a previously quite normal hip disproves sufficiently Calot's theory. The subluxation which is not rare in the course of the disease is secondary, unless it depends on alterations of the acetabulum of a rachitic nature.

Lenormant, in 1913,[7] and later Delitala,[8] maintained that the disease depends upon a dystrophia cong. The same can be said against this as against Calot's theory, but on the other side his hypothesis cannot be rejected when the symptoms of the disease have been present ever since the child began walking. Such a case is No. 57 in my material.

Though there are thus several causes of the disease all have this in common, that they bring forth a disturbance in the joint's state of nutrition. As in nearly all cases the clinical and X ray picture is the same and the course of the disease is uniform, it is likely that the causal factors mentioned are only accidental and exciting, and the actual predisposing cause is to be sought in more fundamental circumstances. Note the development of the disease at a particular age, its predilection for one sex, its at times familiar appearance, and its alternation within the same family with other diseases of the hip (one can find mal. c. C.-L.-P. on one side and luxat. c. cong. on the other in the same individual). I have thought the most fundamental cause of the disease to be disturbances of certain endocrine glands or of the interaction between them. One must in this connexion remember the relation of osteomalacia to the ovaries, particular forms of arthritis deformans to the thyroid gland, and Axhausen's interpretation of these and other diseases as "Knochendystrophie" brought about by alterations in the secretion of the intern glands. Læven, in examining a skeleton of a cretin, found a pronounced mal c. C.-L.-P. on both sides,[9] and Erkes has found the disease in a patient with a pronounced *typus adiposogenitalis*.—I am, Sir, yours faithfully,

HALFDAN SUNDT,
Medical Superintendent of Fredriksvern
Coast Hospital, Norway.

Fredriksvern, Norway.

WARMING ETHER VAPOUR FOR INHALATION.

To the Editor of THE LANCET.

SIR,—May I draw attention to what I consider a danger with regard to some intratracheal anæsthesia apparatus recently described in your columns[1]—viz., the method of heating the ether-laden air by an electric incandescent lamp? Dr. W. J. McCardie has described[2] an accident caused, almost certainly, by a minute spark in the bulb fittings which fired the ether, and it seems not to have been a unique occurrence. The temperature required for the ignition of ether is considerably higher than for coal-gas, but, once alight, the vapour burns fiercely, the flame licking up outlying streams. Mixed with a proper proportion of air it may explode with violence. Moreover, heating gases and vapours with the object of administering them warm is generally futile. Their specific heat is so extremely low that, while they can be heated with the utmost ease, passage through a foot or two of rubber tubing, even with moderate rapidity, will effectually reduce them to its own temperature, nor does the temperature of the tube become appreciably raised. For example, the temperature of air blown by a foot-bellows through 20 feet of copper tubing in hot water, appeared to be 110° F., while, blown only through a few fittings, equal to about 8 or 10 inches of the hot tubing, it was 108° F., and many experiments gave consistent results. Again, where the temperature of a room was 62° F. ether-laden air blown through a tube immersed in water at 152° F., which heated it efficiently, and then through 18 inches of rubber tubing about 9/32 inch in diameter for five minutes, registered 68° F., while five minutes after the hot water had been removed it registered 65° F.; showing, it would seem, that the temperature of the room largely controlled the result. There are fallacies in connexion with taking the temperature of gases in movement. They invalidate the reading of a thermometer placed in the space underneath a lint-covered Schimmelbusch frame, where it will act much as the wet bulb in a hygrometer.

Possibly a useful way of warming vapour for inhalation would be to pass it through a short length of rubber tubing—18 inches would suffice—placed on the patient's chest, beneath the clothing, and thence by the shortest route to his nose and mouth.—I am, Sir, yours faithfully,

K. B. PINSON,
Anæsthetist, Manchester Royal Infirmary.

May 16th.

EARLY DIAGNOSIS IN DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—If in all cases of diphtheria antidiphtheritic serum could be administered sufficiently early, and in efficient dose, then the disease could be regarded as comparatively innocuous. This, I believe, is the steadily growing and considered opinion of those in the profession in a favourable position to judge. And now if this statement of opinion is granted as correct, then the continued considerable death-rate in this disease is a reproach. Ideally, serum ought to be administered at once on the first reasonable suspicion of diphtheria, then a swab should be taken from the throat. If the result of bacteriological examination of the latter is positive then valuable time in treatment has been gained, and if negative, the patient's condition has not been prejudiced. Too often it is found when the case arrives at the isolation hospital that serum has not been administered at all, or that valuable time in treatment has been lost by waiting on the result of bacteriological examination before administering serum. The important point to be noted here is that during this lost time *toxins* are rapidly becoming *fixed* in the patient's nervous tissue, with irreparable damage to the prospects of subsequent treatment and consequently also to prognosis.

The following practical steps to give the all-important earlier administration of serum suggest themselves to me:—

(1) Health visitors, under the M.O.H., should be instructed how to take swabs and administer serum.

(2) The practitioner in attendance should send, by telephone or otherwise, immediate notice to the Health Office of cases of sore throat, in which there exists a reasonable suspicion of the existence of diphtheritic infection, with a request that the health visitor be sent at once to administer an initial dose of serum in such quantity as the practitioner may order.

(3) A swab could be taken by the health visitor at the same time, and the result of bacteriological examination awaited.

(4) Free access to fresh serum and swab outfit should be given to the practitioner at all times to provide for the following contingencies: (*a*) the practitioner wishing to administer the initial dose personally, or (*b*) to allow of the practitioner giving it personally, where unnecessary delay would otherwise arise through the health offices being closed, as at night-time, week-ends, or public holidays.

It should, however, be noted that, not infrequently (and this especially applies to working-class areas), the delay in the application of serum treatment has arisen through parents not considering it necessary to seek early medical advice in cases of sore throat in their children, and this is especially dangerous in the presence in the district of diphtheria in epidemic form. Parents, and the public generally, might be made more alive to the sovereign virtue of serum administered early in diphtheria, and to the serious consequences to the patient that may arise through omission of such early administration. This could be done by educative propaganda, say by the public health authorities.

If this letter helps in any way the efforts to reduce a preventable mortality it will have accomplished its purpose.—I am, Sir, yours faithfully,

J. EWING ADAM, M.D., F.R.C.S. Edin., D.P.H.,
Medical Superintendent, Mogden Isolation Hospital, Isleworth.
May 23rd, 1921.

To the Editor of THE LANCET.

SIR,—The letter from Dr. Frederic Thomson in THE LANCET of May 21st indicates the responsibilities of directors of bacteriological laboratories.

When I had charge of the bacteriological laboratory in the borough of Southend-on-Sea, in reporting on swabs submitted I was in the habit of issuing a printed report of the result of examination, at the foot of which I warned the practitioner that a negative result did not necessarily mean that the case was not one of diphtheria. Another sentence emphasised the importance of giving antitoxin when diphtheria was suspected, without waiting for the bacteriological result.

The Norfolk County Council has recently started a County Laboratory, and naturally I am adopting the same precautions in my reports.

I am, Sir, yours faithfully,
J. T. C. NASH.

The Shire House, Norwich, May 23rd, 1921.

THE WEANLING.

To the Editor of THE LANCET.

SIR,—The babies of the poor country Arabs in Upper Egypt have no intermediate stage. They receive a slab of coarse wholemeal bread while they are still on the breast, and when weaned many of them get little or no milk because of their parents' poverty. These children, fed chiefly on the real staff of life—water, raw fruits, and raw vegetables—also with lentil soup, grow into fine men and women with good teeth and powerful jaws. In fourteen years no case of appendicitis, no case of gastric ulcer, no case of cancer either of breast or stomach was seen at the hospital. Yet the Egyptian surgeons inform me that they see a fair number of cases of appendicitis amongst the children of the rich in Cairo. The country native if promoted to be the servant of a house in Cairo loses his good teeth, though I think that the large amount of raw fruit he still eats tends to prevent their decay. The poor native takes his sugar only in the form of the fibrous cane or in other fruits. What I should like to know, Sir, is this: How many cases of appendicitis, gastric or duodenal ulcer, and cancer of the stomach arise in those favoured few of our population who have never suffered from dental caries? Surely the first thing is to concentrate on the prevention of dental caries; at any rate it is my firm belief that with the return of sound teeth the diseases above-mentioned will almost disappear.

I am, Sir, yours faithfully,
W. E. NICKOLLS DUNN.

Bath Club, Dover-street, W., May 13th, 1921.

HELIOTHERAPY IN SURGICAL TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—It is no exaggeration to state that heliotherapy is to-day, at least on the Continent, recognised as the treatment par excellence of surgical tuberculosis. The success of Rollier at Leysin and others on the Riviera testifies that the medical profession and the public at large are becoming more and more aware of the great value of a systematised sun cure. Thus no one need nowadays despair of ever bringing back to perfect health, and at times with absolute restoration to its primitive function, a chronically inflamed tuberculous joint. That eminently desperate condition, morbus coxæ, even if suppurating, and that no less discouraging affection, Pott's disease, when not too advanced, both yield to the all-powerful and healing effect of the sun. Again, chronic adenitis, whether the glands be enlarged singly or in groups, whether suppurating or not, can be and is always cured by heliotherapy.

As Rollier says, few cases of local tuberculosis are more susceptible to the treatment, and this without resorting to aspiratory methods, injection of antiseptic substances, and still less to excision. Thus a cure is obtained without reinfection, so constant after operative treatment, and without scars. On the Riviera, where we have treated a large number of cases by sun cure, we have further obtained excellent results in tuberculosis of the abdomen, in all manners of chronically inflamed conditions of bony surfaces, tuberculous or otherwise, in tuberculosis of the uro-genital tract, pleuro-pneumonia, neuritis, neuro-arthropathies, callous ulcers with varicose enlargement, staphylococcic infections, and in the convalescence from abdominal operations, especially those connected with the bowels. To sum up, heliotherapeutics not only shows itself particularly efficacious in all forms of local tuberculosis, when not too advanced, but is also the ideal form of treatment for a large variety of diseases where a general impairment of health has led to an imperfect action of the kidneys and of the skin, and where symptoms of chronic intoxication by toxins dominate the scene.—I am, Sir, yours faithfully,

G. A. CASALIS DE PURY.

Weymouth-street.

SURGICAL SHOCK.

To the Editor of THE LANCET.

SIR,—In surgical shock, uncomplicated by severe hæmorrhage, either external or internal, or by toxic substances capable of dilating capillaries, there appears to be an intense contraction of the whole vascular system, arteries, veins, and capillaries, as stated by Mr. John D. Malcolm. Granted the existence of a contracted vascular system, this becomes no longer capable of containing all the blood, and the volume of blood is reduced by migration of the blood-fluids from the vessels into the tissues, with the result that the blood in actual circulation is greatly diminished. Appropriate methods may be expected to demonstrate, if they have not already done so, the presence, in the tissues, of the missing blood-fluids. The foregoing explanation, being strictly in accord with clinical facts, is, in my opinion, far more convincing than is the assumption that the blood must be in some part of the vascular system, and therefore, "the dilatation of arteries and veins having been ruled out, it could only be in the capillaries."

I am, Sir, yours faithfully,

Plymouth, May 21st, 1921 C. HAMILTON WHITEFORD.

PUBLIC HEALTH AND THE COAL DEADLOCK.

To the Editor of THE LANCET.

SIR,—Perhaps the most remarkable thing about the coal deadlock is the good state of the mental public health. Nobody seems to be getting hysterical. We may be heading for destruction, but we seem to be doing so in a philosophical, good-humoured manner. We learned to put up with restrictions during the war, and have gone back to them quite placidly. For the ordinary public there has been no food difficulty as yet. The difficulty about domestic fuel comes at a time of the year when it is not much felt. A hot dinner once, twice, or thrice a week instead of every day is no great deprivation. Butter is cheaper, vegetables plentiful, and up till now there has been no difficulty about the delivery of milk. We can take to a simpler dietary and a simpler life with probable benefit to our health. A little discomfort on necessary railway journeys is nothing to make a fuss about. The curtailing of tram services may do some of us good, and the reduction of gas and electric lighting is more of an inconvenience than a danger to health. The use of baths is curtailed, and with it the cult of swimming. This will be a relief to those ear and nose specialists who regard the public baths as a source of much ill. The Briton is proverbially fond of his ".tub," but many millions got used to fewer tubs during the war. Many people who have been used to hot baths find the change to cold ones exhilarating. There is no evidence that the public health has suffered as yet. The air of our industrial towns is cleaner. We are conserving our supply of coal at a time when it cannot be disposed of profitably. Fortunately, the necessary sanitary services, such as the collection and disposal of refuse, are very little dependent on coal. Perhaps the deadlock will even give a fillip to the movement for recovering the millions of tons of available fuel from our dustbins.

Provided the strike funds and relief are wisely administered and spent, there is no reason why the public health should suffer, except in so far as the extension of unemployment brings fresh sections of the population below the poverty line. In London the number of necessitous children requiring meals in elementary schools was in December, 1920, double what it was in December, 1919, and the number has increased week by week ever since. It is not nutrition with which we are specially concerned at the moment. All through the trouble a spirit of cheerful optimism has prevailed. I met a man a week ago who prophesied that in three weeks the coal deadlock, the German trouble, and the Irish trouble would be practically settled. He is only typical of many. If you travel in a railway compartment crowded with reservists just called up the one thing which strikes you is their imperturbable good humour. I deduce from all this that the mental public health is in a sound state. It is not that people "don't care"; it is that they realise that they are up against trouble that has to be seen through, and they are determined to see it through cheerfully and without unnecessary "grousing." I do not want to minimise the seriousness of the situation, but as grumbling does not help its absence is all to the good.—I am, Sir, yours faithfully,

May 21st, 1921. M.O.H.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—As the result of the special and ordinary Primary Fellowship Examination held from May 3rd to 14th, for which 171 candidates presented themselves, 58 candidates were approved and 113 were rejected. The following are the names and medical schools of the successful candidates:—

L. H. Appleby, Kingston and London; D. C. G. Ballingall, Cambridge and St. Bart.'s; F. G. Beatty, Trin. Coll., Dublin; A. Blackstock, King's Coll.; C. E. Bond, Cambridge and Univ. Coll.; G. A. Brookes, Sydney and London; H. A. Brookes, Edinburgh; G. G. Bruce, Aberdeen; J. T. Burrell, Cambridge and London; G. M. Cameron, Toronto and St. Mary's; C. H. Carlton, Oxford and St. Mary's; S. M. Cohen, Cardiff and St. Bart.'s; J. R. M. Collie, Dalhousie and St. Mary's; R. S. Corbett, Cambridge and St. Bart.'s.; R. C. Davenport, St. Bart.'s; C. O. Davies, Liverpool; S. N. Deboo, Bombay and Guy's; M. R. Flynn, Sydney and Middlesex; G. N. Golden, London; L. B. Goldschmidt, King's Coll.; W. D. Hart, Otago and St. Mary's; G. T. Henderson, Cambridge and Guy's; C. A. Horder, St. Bart.'s; L. G. Housden, Guy's; M. V. Hurley, Cork and London; S. P. Jacobson, Cape Town and Guy's; J. Jemson, Guy's; A. R. Jones, Cardiff and Middlesex; N. A. Jory and N. E. Laurence, St. Bart.'s; M. A. Lautré, St. Thomas's; K. W. Leon, St. Bart.'s; A. R. Lister, Cambridge and London; C. A. Lupton, Cambridge; Gladys Helen Marchant, Calcutta and Lond. Sch. Medicine for Women; J. Maxwell, St. Bart.'s; Ruth E. Millar and W. Miller, Edinburgh; L. Morris, Manchester and Middlesex; T. D. Overend, Oxford and Middlesex; J. A. Panton, Manchester; C. M. Pearce, St. Bart.'s; N. A. M. Petersen London; J. E. Purves, Edinburgh and St. Mary's; B. T. Rose, Birmingham; J. P. Ross, St. Bart.'s; Violet Iono Russell, Lond. Sch. Med. for Women; J. R. Smith, Cambridge; M. J. Smyth, Dublin and Middlesex; W. O. Stevenson, Toronto and Univ. Coll.; Hilda North Stoessiger, Lond. Sch. Med. for Women; G. C. Swanson, Glasgow and Univ. Coll.; D. B. Walker, Otago and Royal Free; A. D. Wall, St. Bart.'s; E. C. Warner, Guy's; F. W. Watkyn-Thomas, Cambridge and St. Bart.'s; H. B. White, St. Bart.'s; and S. H. Woods, Trin. Coll., Dublin.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following candidates having passed the requisite examinations have been admitted Diplomates in Public Health:—

Robert B. Watson, Robert B. Stewart, Cecil C. Brown John S. Elliot, John B. Primmer, Donald A. Cadman, Andrew I. Meek, Jamit Singh, John C. Simpson, Norman S. R. Lorraine, Colin Milne, George G. S. Johnston, David T. Macleod Large, George P. Taylor, and Jane Elizabeth Hay.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College held on May 18th the following candidates, having passed the requisite examinations, were admitted Fellows:—

John P. Blockley, John W. Burns, Arthur G. Clark, William A. Cochrane, Thomas Colley, Cyril C. H. Cuff, Charles W. Graham, John M. Hyde, Victor J. F. Lack, Thomas Lindsay, Helen Meldrum McMillan, Walter Mercer, Mabel Lida Ramsay, George C. Scantlebury, Stuart Scoular, George H. Stevenson, and Stanley G. Whitfeld.

The following candidates, having passed the requisite examinations, received the Higher Dental Diploma: Grantley Smith and James A. S. Wright.

At the same meeting the Bathgate memorial prize, consisting of bronze medal and set of books, was, after a competitive examination in Materia Medica, awarded to James Maitland McLintock, and the Ivison Macadam memorial prize in Chemistry, consisting of bronze medal and set of books, was awarded, after competitive examination, to John Harkness.

HARVEIAN SOCIETY.—The annual dinner will be held on Wednesday, June 22nd, at 7.30 P.M., at the Café Royal, Regent-street, London, W.

ROYAL INSTITUTION OF GREAT BRITAIN.—The Friday evening discourse on June 3rd, at 9 P.M., will be delivered by Mr. Leonard Huxley, editor of the *Cornhill Magazine*, on Chronicles of the Cornhill.

GREAT NORTHERN CENTRAL HOSPITAL.—A bazaar in aid of this hospital will be held at Crewe House on June 2nd and 3rd.

THE PEOPLE'S LEAGUE OF HEALTH.—Lady Curzon held an At Home at 1, Carlton House-terrace, on May 24th, to inaugurate her office of Appeal Director of the People's League of Health. The speakers included Viscount Burnham, the Bishop of Birmingham, Sir Bruce Bruce-Porter, and Sir Johnston Forbes-Robertson.

UNIVERSITY OF LONDON.—*Hygiene.*—A course of four advanced lectures on Recent Developments in Legislation for the Prevention of Disease will be given by Dr. Charles Porter at University College, Gower-street, London, W.C., at 5.30 P.M. on May 30th and June 3rd, 6th, and 10th.

Pharmacology.—A course of four advanced lectures on Some Actions of Foodstuffs in the Production and Treatment of Disease will be given by Prof. Edward Mellanby at the Royal College of Surgeons, Lincoln's Inn-fields, London, W.C., at 5 P.M. on June 6th, 7th, 13th, and 14th.

Embryology.—A course of three advanced lectures on Recent Advances in Experimental Embryology will be given by Prof. E. W. MacBride, F.R.S., at the Royal College of Science, Exhibition-road, London, S.W., at 5 P.M. on June 7th, 8th, and 9th.

Medicine.—An advanced lecture on Permeability in Physiology and Pathology will be given at the Royal Society of Medicine, 1, Wimpole-street, London, W., by Dr. H. J. Hamburger, at 5 P.M. on June 8th. This lecture, which will be delivered in English, is the last of a series of six arranged under the scheme for the exchange of lectures in medicine between England and Holland.

A course of four advanced lectures on the Therapeutic Use of Digitalis will be given by Prof. F. R. Fraser, in the Surgical Lecture Theatre, St. Bartholomew's Hospital Medical School, West Smithfield, London, E.C., at 5 P.M., on June 13th, 15th, 17th, and 20th.

All these lectures are addressed to advanced students of the University and to others interested in the subject Admission is free, without ticket.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—At the quarterly meeting of this Association on June 7th, Sir Frederick Mott will deliver the second Maudsley lecture, at 4.30 P.M., at the Maudsley Hospital, Denmark Hill, London, S.E.

ROYAL SOCIETY OF ARTS.—On Monday, May 30th, at 8 P.M., Sir Kenneth Goadby will read a paper on Industrial Disease and Immunity at the house of the Society, John-street, Adelphi, London, W.C. The Rt. Hon. John R. Clynes, M.P., will preside, and the paper will be followed by a discussion.

RONTGEN SOCIETY.—An exhibition of Radiographs will be held by the Rontgen Society in the Royal Photographic Society's rooms, 35, Russell-square, London, W.C., during the month of June. The exhibition will be open daily, Sundays excepted, from 10 A.M. to 5 P.M., and all who are interested are invited to attend.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—At a meeting of this society held on May 20th Dr. W. J. Howarth, medical officer of health for the City of London, was elected president of the society for the session 1921–22. Dr. Howarth will take office in October next. At the same meeting the honorary fellowship of the society was conferred on Dr. Alfred Hill, formerly medical officer of health for the City of Birmingham, "for long and distinguished services to preventive medicine and public health administration." Dr. Hill, who has just entered his 96th year, was president of the society in 1886 and 1887.

MEDICINE IN THE SOUTHERN PARLIAMENT OF IRELAND.—A large number of medical men have been returned unopposed to the Southern Parliament. The following names occur Sir James Craig, Dublin University; Mr. R. F. Hayes, East Limerick and City of Limerick; Mr. V. J. White, Waterford and East Tipperary; Mr. P. McCartan, King's and Queen's Counties; Dr. J. Ryan, Wexford; Dr. Cusack, Galway; Mr. J. Crowley, Mayo; Dr. Ferran, Sligo; Dr. J. P. McGinley, Donegal; Dr. Ada English, National University. Of these members five are in jail, three of them without any charge being preferred against them.

THE LATE MR. W. H. ELLIS.—William Henry Ellis, M.R.C.S., L.S.A., who died at Bradford on May 8th, was consulting surgeon to Sir Titus Salt's Hospital, Shipley, and well known as a medical practitioner in the West Riding. He received his medical education at Cambridge and at St. Bartholomew's Hospital and qualified in 1866. For a time he held a house appointment at the Great Northern Hospital, London, and afterwards started practice at Shipley, for which town he became M.O.H., and was later appointed certifying surgeon under the Factory and Workshop Acts, and a medical referee. He retired from practice in 1910, when he was placed on the commission of the peace for the Riding. Mr. Ellis was the chairman of the Salt Trust Board of Governors, a member of the Shipley School Board, and, in the early days of the Volunteer movement, held a commission in the Volunteer Force. The part which Mr. Ellis took in the public life of the community among which he practised will make his loss keenly felt by many.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.—A course of lectures, free to medical practitioners, is being held at this hospital on Thursdays at 4 P.M. The next lecture will be delivered on June 2nd by Dr. G. Still on Some Urinary Disorders. Subsequent lectures will be announced in our Medical Diary. Clinical instruction is also given by the members of the staff at their visits. The fee to post-graduates for three months' attendance is £5 5*s.*, and for perpetual attendance, £10 10*s.* Clinical clerkships and dresserships are open to students—fee, £1 1*s.* per month.

DALRYMPLE HOUSE, RICKMANSWORTH.—We have received the thirty-seventh annual report of this institution, which is under the management of the Homes for Inebriates Association. During the year 56 persons have been admitted as private patients and 23 under the Inebriates Act; these figures do not include readmissions. The fact that culture and education do not protect a man from over-indulgence is seen clearly by the list of occupations of those who since the opening of the home have been driven to seek its help, for professors, librarians, solicitors, architects, &c., are all included. Even those whose business it is to preach against indulgence themselves sometimes fall, as 31 clerks in holy orders have been admitted; and a scientific knowledge as to the danger of taking alcohol is not a complete safeguard, for 116 medical practitioners have sought relief. The medical superintendent, Dr. F. S. D. Hogg, reports that he uses a variety of methods in the treatment of his patients, and is able to give a large measure of freedom to almost all of them after two to four weeks' residence; the most important aid to recovery he finds to lie in the strengthening of the patient's will-power and determination, and a realisation that total abstinence from alcohol (or from the drug to which he has been addicted) is an absolute necessity.

THE LATE DR. J. M. ROGERS-TILLSTONE.—John Monkhouse Rogers-Tillstone, L.R.C.P. Lond., M.R.C.S., who died at Surbiton on May 16th, at the age of 52, came of a family long associated with Brighton. He studied medicine at St. Bart.'s and qualified L.R.C.P., M.R.C.S., in 1891, practising at East Malling in Kent and later at Chalford in Gloucestershire. Dr. Rogers-Tillstone, after retiring from practice, spent some years at Maidstone. Always interested in the Volunteer movement, he took an important part in the formation of the 1st H.C. Field Ambulance, eventually commanding the unit, and went out to France in December, 1914. He went through the first battle of Ypres, and was mentioned in dispatches for the initiative he showed in evacuating a hospital installed in a ruined building in the town shortly before it was destroyed by fire. Afterwards, a shell burst in front of him and he was thrown from his horse and badly injured. Subsequently he held appointments at Canterbury, Margate, and Colchester. In 1919 he attained the rank of colonel and was transferred from the R.A.M.C. to the Army Medical Service. In 1920, Dr. Rogers-Tillstone became chief of the Home Counties Pensions Board at Guildford, and was holding the appointment at the time of his death.

DEATH OF DR MARTIN DEMPSEY, F.R.C.P.I.—Dr. Martin Dempsey, senior physician to the Mater Misericordiæ Hospital, Dublin, and professor of materia medica in University College, Dublin, died on May 19th. He had been in failing health for some time, and contracting pneumonia he succumbed. He was a little over 50 years of age. Dr. Dempsey, after a distinguished course in the Royal University, took his medical degrees in 1890, and his M.D. degree with gold medal in 1893. He had the reputation of being a sound and wise physician, and a clear and attractive teacher. For many years he enjoyed a large practice as a consultant. Personally he was a man of much charm and wide culture, devoid of show or pretence and much esteemed by his friends.

THE LATE DR. J. S. FERRIS.—Dr. John Spencer Ferris died at Ealing on May 17th at the age of 79 years. After studying at King's College Hospital, London, and in Paris and Germany, he qualified M.R.C.S. Eng., in 1863, taking honours at the M.B.Lond. three years later. He commenced practice in Uxbridge in partnership with the late Dr. Macnamara, and lived there until his retirement in 1910. At first he visited his patients on horseback, but later adopted a high gig with red wheels, his partner's equipage having yellow wheels. He became medical officer and hon. colonel to the Uxbridge Yeomanry, and it is recorded that there was some difficulty in obtaining a horse big enough for him. He was a great friend of Linley Sambourne, who lived near him, and afforded the cartoonist material for some of his inimitable sketches of the yeomanry. At one time Dr. Ferris was an active member of the Uxbridge urban district council, easily heading the poll at the election. Dr. Ferris, who was buried at Great Malvern, is survived by one son, who is in the Navy, and a daughter, his wife having predeceased him.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surgeon Lieutenant-Commanders to be Surgeon Commanders: H. F. Briggs, A. G. Malcolm, H. C. Devas, and H. Burns.

Surg.-Lieut. G. W. Woodhouse to be Surgeon Lieutenant-Commander.

A. C. Esmonde to be Surgeon Lieutenant.

ARMY MEDICAL SERVICE.

Lieut. Col. R. J. W. Mawhinny, from R.A.M.C., to be *Colonel.*

ROYAL ARMY MEDICAL CORPS.

Temp. Capt. (acting Major) H. G. Hobson to be Captain.

Lieut. (Temp. Capt.) T. B. H. Tabuteau to be Captain.

Temporary Captains relinquishing their commissions: Acting Major C. C. Chance (granted the rank of Major), and H. Stanger (retains the rank of Captain).

TERRITORIAL FORCE.

Capt. F. J Morris to be Captain.

Capt. H. B. Logan (late 1st South Middlesex Brigade, (R.F.A.) to be Lieutenant, and relinquishes the rank of Captain.

Lieut. R. Price (late R.A.M.C.) to be Lieutenant.

DEFENCE FORCE.

The following temporary appointments have been made:—

Assistant Directors of Medical Services: Temp. Cols. F. W. Higgs (D.F.) and J. G. Martin (D.F).

Deputy Assistant Directors of Medical Services: Capts. O. Teichman (D.F) and S. S. Greaves (D.F.).

To be temporary Colonels: F. W. Higgs and J. G. Martin.

To be temporary Major: C. V. Bulstrode.

To be temporary Captains: H. Drummond, O. Teichman, and J. D. G. Stewart.

1st East Lancs Field Ambulance (D.F.)—To be temporary Lieutenant-Colonel: T. B. Wolstenholme.

To be temporary Captains: J. F. O'Grady and T. Hamilton.

1st Highland Field Ambulance (D.F.)—To be temporary Lieutenant-Colonel: A. S. K. Anderson. To be temporary Lieutenants: I. S. Thomson, J. I. Moir, G. Burnett, and D. R. Macdonald.

3rd Highland Field Ambulance (D.F.)—To be temporary Captains: D. Roger and W. E. A. Buchanan.

3rd Lowland Field Ambulance (D.F.)—To be temporary Lieutenant-Colonel: F. A. E. Crew. To be temporary Captains: J. A. L. Loudon and C. G. Lambie. To be temporary Lieutenants: O. H. Wild, E. H. Ponder, and R. K. S. Lim.

52nd Lowland Division Sanitary Section (D.F.).—To be temporary Captain: M. Wilson.

1st East Anglian Field Ambulance (D.F.)—To be temporary Major: W. S. Forbes.

1st South Midland Field Ambulance (D.F.).—To be temporary Major: F. G. Hobson. To be temporary Captain: W. D. Gardner.

2nd South Midland Field Ambulance (D.F.).—Temp. Capt. W. W. Newton to be temporary Major. To be temporary Captains: W. W. Newton and Temp. Lieut. N. C. Cooper.

2nd Northumberland Field Ambulance (D.F.).—To be temporary Lieutenant-Colonel: D. L. Fisher.

To be temporary Major: V. Wardle. To be temporary Captains: D. Roberts, F. C. Pridham, and W. McK. Wilson.

49th West Riding Division Sanitary Section (D.F.).—To be temporary Captain: H. L. Robinson.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel to be Colonel: (Bt.-Col.) R. Heard.

The King has approved the retirement of Lieut.-Col. S. Evans. The King has approved the relinquishment of their commissions by Temp. Capt. Banwari Lal Gupta, Temp. Capt. Shapoor Dinshaw Vania, and Jamshedji Nasarwanji Duggan.

DONATIONS AND BEQUESTS.—The Chelsea Hospital for Women has received £250 from the Trustees of Smith's (Kensington) Charity and £166 1*s.* 7*d.* from the Estate of the late R. I. Campbell.—The British Home and Hospital for Incurables, Crown-lane, Streatham, has received £10 from the Surrey County Football Association.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Wednesday, June 1st.

SECTION OF SURGERY: at 5.30 P.M.

Papers: Mr. Charles A. Pannett: The Treatment of the Imperfectly Descended Testicle.

Dr. A. Goodman Levy: Cardiac Massage.

Thursday, Friday, and Saturday, June 2nd, 3rd, and 4th.

SECTION OF LARYNGOLOGY: Summer Meeting.

THURSDAY.—Papers, 2.30–6 P.M.

FRIDAY.—Papers, 10 A.M.–1 P.M.
Demonstrations, 2.30–4 P.M.
Clinical Meeting, 4 P.M.
Dinner, 7.30 P.M.

SATURDAY.—Visits to Hospitals.

Friday and Saturday, June 3rd and 4th.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

The Council desires to call the special attention of Members of the Section to the British Congress of Gynæcology and Obstetrics to be held at the Queen's Hotel, Birmingham, on June 3rd and 4th.

FRIDAY, June 3rd: at 9.30 A.M.

Papers: Dr. W. E. Fothergill and Dr. F. H. Lacey: The Results of Plastic Vaginal Operations for Genital Prolapse.

Dr. A. Donald: The History and Technique of Colporrhaphy.

The following Resolution will be moved by Dr. Fothergill, seconded by Dr. Lacey:—

That in the opinion of the Meeting, operations by the abdominal route are quite unnecessary for the treatment of genital prolapse.

At 2.30 P.M.

Specimens will be shown by—Dr. Clifford White, Dr. Ewan Maclean, Dr. H. Chapple, Dr. G. I. Strachan, and Professor H. Briggs.

Short Communications will be given by—Dr. F. J. Browne, Mr. Gordon Luker, Dr. Walter Swayne.

SATURDAY, June 4th: at 9.30 P.M.

Operations at Birmingham Hospitals.

N.B.—Members desiring further information should apply to Mr. Beckwith Whitehouse, 52, Newhall-street, Birmingham.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY, June 3rd.—Adjourned Meeting. Papers:—Lt.-Col. H. Kirkpatrick, I.M.S. (retd.): Some Points on Trachoma. Dr. Carlo Franca: An Early Portuguese Contribution to Tropical Medicine.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

MONDAY, May 30th.—8 P.M., Paper:—Sir Kenneth Goadby: Industrial Disease and Immunity.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, May 30th.—12.15 P.M., Dr. Burnford: Pathological Demonstration. 2 P.M., Dr. Simson: Diseases of Women. 2.30 P.M., Mr. Baldwin: Visit to Surgical Wards. 5 P.M., Lecture:—Dr. Arthur Saunders: Gastric Disorders in Children.

TUESDAY.—10 A.M., Mr. Steadman: Dental Department. 11 A.M., Dr. McDougal: Electrical Department. 12 noon, Mr. Tyrrell Gray: Demonstration of Fractures. 2 P.M., Dr. Pernet: Skin Department. 2.30 P.M., Mr. Addison: Demonstration of Cases, Surgical Wards. 5 P.M., Mr. Banks Davis: Clinical Lecture:—Throat, Nose, and Ear.

WEDNESDAY.—10 A.M., Mr. MacDonald: Genito-Urinary Department. 12 noon, Mr. Sinclair: Surgical Diseases of the Abdomen. 2 P.M., Dr. Morton: X Ray Department. 2 P.M., Mr. Gibb: Eye Department. 2 P.M., Dr. Owen: Medical Out-Patients.

THURSDAY.—10.30 A.M., Dr. Simson: Gynæcological Demonstration. 12 noon, Dr. Scott Pinchin: Diseases of the Heart. 2 P.M., Mr. Bishop Harman: Eye Department. 2 P.M., Mr. Baldwin: Orthopædic Department. 5 P.M., Special Lecture:—Dr. W. H. Willcox: Toxic Conditions of the Liver (open to all medical practitioners).

FRIDAY.—10 A.M., Dr. Grainger Stewart: Neurological Demonstration. 10 A.M., Mr. Dudley Buxton: Dental Department. 2 P.M., Dr. Burnford: Medical Out-Patients. 2 P.M., Mr. Banks Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Mr. Addison: Demonstration of Surgical Cases, Surgical Wards. 5 P.M., Lecture:—Mr. MacDonald: Retention of Urine.

SATURDAY.—9 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Arthur Saunders: Medical Diseases of Children. 2 P.M., Dr. Sinclair: Surgical Out-Patients.

Daily:—10 A.M. Visit of Post-graduates to Wards. 2 P.M., In-patient, Out-patient Clinics and Operations.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, June 2nd.—Lecture:—Dr. Still: Some Urinary Disorders.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, W.C. 1.

MEDICAL SCHOOL.

MONDAY, May 30th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Lecture:—Dr. Aldren Turner: Psycho-neuroses.

TUESDAY, May 31st.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Lecture:—Dr. Risien Russell: Myelitis.

THURSDAY, June 2nd.—2 P.M., Out-patient Clinic: Dr. Farquhar Buzzard. 3.30 P.M., Lecture:—Dr. Kinnier Wilson: Tumours of Spinal Cord (I.).

FRIDAY, June 3rd.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Lecture:—Mr. Sargent: Surgical Treatment of Cerebral Compression.

NEUROLOGICAL OPHTHALMOLOGY.

WEDNESDAY, June 1st.—3.30 P.M., Mr. Leslie Paton: Optic Atrophy.

Fee for Post-Graduate Course £7 7s.

C. M. HINDS HOWELL, Dean.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Turner-street, Mile End, E.

Courses of Lectures:—

A Course of Fourteen Lectures on Psycho-Neuroses, to be given by Dr. M. Culpin in the Clinical Theatre of the Hospital. Open to Students of the Hospital and to Members of the Profession.

TUESDAY, May 31st.—5.15 P.M., Lecture IX.:—Symptomatology.

Advanced Lectures in Physiology, to Students of the University and to others interested in the subject.

A Course of Eight Lectures on Reception of Sensory Stimuli, to be given by Prof. H. E. Roaf in the Physiology Theatre.

THURSDAY, June 2nd.—4.30 P.M., Lecture IV.

A Course of Lectures on Child Physiology, to be given by Dr. W. M. Feldman, in the Physiological Theatre.

MONDAY, May 30th.—5 P.M., Lecture.

The Schorstein Memorial Lecture in the Anatomical Theatre of the College.

FRIDAY, June 3rd.—4 P.M., Dr. A. G. Gibson: Chronic Inflammatory Diseases of the Spleen.

ST. BARTHOLOMEW'S HOSPITAL (UNIVERSITY OF LONDON), West Smithfield, E.C.

A Course of Eight Advanced Lectures in Physiology, to be given in the Physiological Laboratory, to Students of the University and others interested in the subject.

TUESDAY, May 31st.—4.30 P.M., Lecture V.:—Prof. J. B. Leathes: Tyrosine.

UNIVERSITY COLLEGE (UNIVERSITY OF LONDON), Gower-street, W.C.

A Course of Four Advanced Lectures in Hygiene to Students of the University and to others interested in the subject.

MONDAY, May 30th, and FRIDAY.—5.30 P.M., Dr. C. Porter: Recent Developments in Legislation for the Prevention of Disease. (Lectures I. and II.)

ROYAL LONDON OPHTHALMIC HOSPITAL (Moorfields') at the Royal Society of Medicine, 1, Wimpole-street, W.

MONDAY, May 30th.—5.30 P.M., Dr. L. Llewellyn: Miners' Nystagmus.

TUESDAY.—Dr. C. G. Symon: Injuries to the Eye from Metallic Foreign Bodies.

WEDNESDAY.—Dr. T. M. L. Squire: Diseases of the Eye and the Workmen's Compensation Act.

MIDDLESEX HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON).

FRIDAY, June 3rd.—3 P.M., Dr. C. H. Bond: Psychiatry.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, E.

A Course of Post-Graduate Clinical Lectures and Demonstrations in the Board Room of the Hospital, free to Medical Practitioners and Students of Medicine.

MONDAY, May 30th.—4 P.M., Mr. N. C. Lake: Juxta-Epiphyseal Strain and its Sequelæ.

TUESDAY.—4.30 P.M., Dr. E. Pritchard: The Dietetic Treatment of Wasting Babies.

THURSDAY.—4 P.M., Dr. P. Parkinson: Demonstration of Heart and Lung Cases in the Wards.

FRIDAY.—2.30 P.M., Mr. J. Taylor: Surgical Tuberculosis other than that of Bones and Joints.

TAVISTOCK CLINIC FOR FUNCTIONAL NERVE CASES, 51, Tavistock-square, W.C.

A Course of Ten Lectures on Elementary Psychotherapy, to be given by Dr. H. C. Miller, at the Kingsway Hall, Kingsway, W.C.

FRIDAY, June 3rd.—5.15 P.M., Lecture V.:—Emotional Development; The Child and the Adult; Sex Characteristics; Adaptation.

INSTITUTE OF PATHOLOGY AND RESEARCH, St. Mary's Hospital, in the Lecture-room of the Bacteriological Department.

A Course of Lectures on Pathological Research in its Relation to Medicine, open to all Members of the Profession and Students.

THURSDAY, June 2nd.—4.30 P.M., Prof. G. Dreyer: A New Departure in the Serum Diagnosis of Syphilis.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.

TUESDAY, May 31st.—4.30 P.M., Lecture:—Sir William Milligan: Endoscopic Examination of the Food and Air Passages.

MANCHESTER FRENCH HOSPITAL POST-GRADUATE LECTURES, 24, Acomb-street, Whitworth Park.

Special Course of Lectures in Gynæcology.

WEDNESDAY, June 1st.—11 A.M., Demonstration Operations.

THURSDAY.—4.30 P.M., Lecture VIII.:—Dr. A. C. Magian: Pelvic Peritonitis.

Appointments.

DICKSON, K., M.B., B.Ch. Cantab., M.R.C.S., L.R.C.P. Lond., Clinical Assistant to the Hospital for Sick Children, Great Ormond-street.

GOTHE, WERNER, M.R.C.S., L.R.C.P., Head of the Massage and Medical Gymnastics Department at Queen Mary's Hospital for the East End.

KENNON, R., M.D. Liverp., F.R.C.S. Eng., Honorary Assistant Surgeon to the Royal Infirmary, Liverpool.

MORRISON, M., M.B., Ch.B. Edin., D.T.M. Eng., Medical Officer, West African Medical Staff, Nigeria.

REYNOLDS, R. J., M.B., B.S. Lond., Adviser in Radiology to the Ministry of Pensions and Physician in Charge of the Department of Radiology and Electro-Therapeutics at Charing Cross Hospital.

STOCKS, P., M.D. Camb., Medical Officer in connexion with the Department of Applied Statistics and Eugenics in the University of London.

TIMBRELL FISHER, A. G., F.R.C.S., Eng., Surgeon with charge of Out-Patients at the Dreadnought Hospital, Greenwich, in succession to E. T. C. Milligan, F.R.C.S. Eng., who has been promoted to the Senior Staff.

YOUNG, W. A., M.R.C.S., L.R.C.P. Lond., Pathologist to St. John's Hospital for Diseases of the Skin.

Jessop Hospital for Women, Sheffield: KING, W. W., F.R.C.S Edin., Honorary Surgeon; STACEY, J. E., M.B., Ch.B Sheffield, Registrar.

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne District Infirmary.—Res. Surg. O. £250.

Adelaide University.—Professor of Zoology. £1100.

Bedford County Hospital.—Asst. H.S. £150.

Bethlem Royal Hospital, Lambeth-road, S.E.—Jun. Asst. Phys. £350.

Birmingham General Hospital.—H.S. £100. H.S.'s to Special Depts. £125 each.

Birmingham, Queen's Hospital.—Hon. Obst. Officer. Surg. Registrar. £100.

Birmingham University.—Demonstrator of Anatomy. £300.

Bradford Royal Infirmary.—H.S. £200.

Buxton, Derbyshire, Devonshire Hospital.—H.P. £250.

Cardiff, King Edward VII. Hospital.—H.S. £200.

Charing Cross Hospital, Agar-street, W.C.—Asst. Phys.

Chester Royal Infirmary.—Asst. H.S. £175. Also Hon. Asst. S.

City and County of Bristol.—Asst. Res. M.O. at Ham Green Isolation Hospital and Sanatorium. £300.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—H.P. £125.

Colchester, Essex County Hospital.—H.S. £200.

Colchester, Severall's Mental Hospital.—Asst. M.O. 7 gs. per week.

Durham, County Sanatorium, Holywood Hall, Wolsingham.—Asst. M.O. £400.

Evelina Hospital for Children, Southwark, S.E.—Phys. to Out-patients.

Finsbury Dispensary, Brewer-street, Goswell-road, E.C.—Phys. £50.

Glasgow, Anderson College of Medicine.—Chair of Practice of Medicine.

Gloucester County Asylums.—Locum Tenens. £7 7s. weekly.

Hampstead General and North-West London Hospital, Haverstock Hill, N.W.—H.P. H.S. Each £150.

Harrogate Infirmary.—H.S. £150.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S. £100.

Hull Royal Infirmary.—Asst. H.S. £150.

Lanarkshire Joint Committee on Venereal Diseases.—Ven. Dis. Officer. £750.

Leicester Royal Infirmary.—H.S. £200.

Leith Hospital.—Res. M.O. 50 gs.

Liverpool Royal Southern Hospital.—Two H.P.'s and three H.S.'s. Each £100.

Liverpool Stanley Hospital.—Three H.S.'s Each £120.

London Lock Hospital, 91, Dean-street, W.—Clin. Assts.

London Temperance Hospital, Hampstead-road, N.W.—Res. Cas. O. £125.

Maidstone, West Kent General Hospital.—H.S. £220.

Manchester, County Asylum, Prestwich.—Locum Tenens. £8 8s. per week.

Manchester University.—Lecturer in Morbid Anatomy and Morbid Histology. £700. Lecturer in Bacteriology. £700. Lecturer in Chemical Pathology. £700.

Miller General Hospital for South-East London, Greenwich-road, S.E.—Res. Cas. O. £150.

Newport, Royal Gwent Hospital.—Hon. Radiologist.

North Middlesex Hospital, N.—Anæsth. 75 gs.

Norwich, Norfolk and Norwich Hospital.—H.P. £200.

Oldham Royal Infirmary.—First and Second H.S.'s. £250.

Orkney, Eday Parish Council.—M.O. £5 per week.

Preston and County of Lancaster Royal Infirmary.—H.S. £200.

Prince of Wales's General Hospital, Tottenham, N.—Hon. P. and Hon. Asst. P.

Queen Mary's Hospital for East End, Stratford, E.—Cas. O.

Rotherham Hospital.—Jun. H.S. £150.

Royal Naval Medical Service.—Surg.-Lieuts. 26s. 6d. per diem.

Royal Waterloo Hospital for Children and Women.—Hon. Phys. for Out-patients.

St. Helens Hospital, Lancashire.—Res. M.O. £250.

Southampton Free Eye Hospital.—H.S. £200.

Southampton, Royal South Hants and Southampton Hospital.—Sen. H.S. £200. H.P. £150. Jun. H.S. £150.
South Uist, Parish of.—M.O. and Public Vaccinator. £170.
Staffordshire General Infirmary.—H.S. £250.
Stamford, Rutland and General Infirmary.—H.S. £250.
Sunderland Royal Infirmary.—H.S. £200.
Swansea County Borough.—Asst. M.O. £500.
Taunton and Somerset Hospital.—Sen. and Jun. H.S.'s. £200 and £150.
Throat Hospital, Golden Square, W.—Hon. Registrar.
University College Hospital.—Part-time Anæsth. £150.
Wigan Education Committee.—Female Asst. Sch. M.O. £500.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Athlone, Brecon, and Sedgeley.

Births, Marriages, and Deaths.

BIRTHS.

REYNOLDS.—On May 17th, at Palmerston-place, Edinburgh, the wife of Dr. A. O. P. Reynolds, of a son.

MARRIAGES.

FOX—WALDING.—On May 20th, at Holy Trinity Church, Plymouth, Edward Lawrence Fox, M.D., M.R.C.P., to Elizabeth Clare Walding, youngest daughter of the late Thomas Walding and Mrs. Walding, of Harrow-on-the-Hill.

IRVINE—CARR.—On May 6th, at Nairobi, Dr. Archibald Clive Irvine, Church of Scotland Mission, Tumu Tumu, Kenya, to Margaret Joyce, eldest daughter of Mr. and Mrs. Ernest Carr, Woodlands, Nairobi, late of Wigton Hall, Cumberland.

LILEY—GOOZEE.—On January 11th, at the British Consulate, Tangier, Dr. James Liley, of the North Africa Mission Hospital, Tangier, to Edith, only child of the late Mr. and Mrs. Thomas Goozee, of New Malden, Surrey.

TATHAM—BARKER.—On May 19th, Arthur Leopold Tatham, M.B., B.C., to Ellinor Gertrude, widow of Brigadier-General Randle Barnett Barker, D.S.O.

TUCKER—GEDDES.—On May 12th, at St. Marylebone Church, Donald Leslie Tucker, B.A., M.R.C.S., L.R.C.P., to Margaret Gordon, only child of the late Brigadier-General J. G. Geddes, C.B., C.M.G., R.A., and Mrs. Geddes, of North Warnborough, Hants.

DEATHS.

CAMPBELL-HORSFALL.—On May 18th, Charles Edward Campbell Horsfall, M.B., Ch.B.

CREMONINI.—On May 20th, suddenly, at Penzance, John Cremonini, M.R.C.S., L.S.A., late Medical Superintendent Hoxton House Asylum and Government Asylum, Auckland, N.Z.

FERRIS.—On May 17th, at Warwick Dene, Ealing, John Spencer Ferris, M.B., aged 79 years.

WEST.—On May 19th, at St. George's-road, S.E., William Goldsborough West, M.D., M.R.C.S., L.R.C.P., aged 55 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE AVAILABLE REMEDIES IN IMMUNE THERAPY.[1]

BY SIR THOMAS HORDER, M.D., F.R.C.P. LOND.

Specific and Non-specific Measures.

WHEN faced with a case of disease due to microbic infection we think of the employment of (1) measures for assisting the patient's general functions (nervous, circulatory, respiratory, digestive, and eliminative) during the extra strain put upon them, and (2) measures for helping the special function, or mechanism, of immunity against the particular infection. The treatment given under the first head is termed non-specific; under the second, specific.

I have recently urged the importance of non-specific measures in the treatment of many infective processes. The stimulus lately given to specific therapy by the advances made in bacteriology, and especially by the introduction and popularisation of bacterial vaccines, has led to a good deal of disregard of general measures of proved utility. It behoves us to be as prompt and thorough in maintaining a patient's general resistance to infection as in the use of any specific remedy which has experience or experiment, or both, to recommend it.

The Principles of Immune Therapy.

Let us first briefly re-state the basic principles underlying all attempts at immune therapy, without subscribing to any doctrine as to the exact nature of the immune process. In diseases of microbic origin the process is the expression of an interaction between the infecting agent and the body tissues. The immediate contributions to this interaction on the part of the micro-organism are the specific chemical poisons—*toxins*—incidental to the life of the microbe in the body. Toxins are of two kinds—exotoxins, produced in the medium in which the bacterium thrives, and endotoxins, those existing in the cell of the bacterial element itself, and set free only by the disintegration of the cell element. Microbic diseases fall into two groups, according as the poisons leading to the symptoms of the disease are chiefly exotoxins or are chiefly endotoxins. Of the first kind are tetanus and diphtheria; of the second, cholera, typhoid, and diseases due to the pyogenetic cocci (streptococcus, pneumococcus, &c.). But these two forms of toxin are not the only contributions made by the infecting agent to the interaction; there are the essential structural constituents of the bacterial cell itself, which, as soon as the cell is destroyed by the tissues of the host, become agents in the interaction.

So much for the contributions of the microbe. What are the contributions of the infected host? A protective substance termed generically *antibody* is formed in response to the stimulus of the various microbic factors already mentioned and which are generically called *antigen*. Knowledge of the various properties exercised by this hypothetical substance called antibody has led to the postulation that antibody comprises a number of different substances. If the exotoxin is neutralised we speak of antitoxin; if the endotoxin is neutralised, of anti-endotoxin; if bacteria are agglutinated, of agglutinin; if precipitated, of precipitin; if they are directly destroyed we call the specific substance, or the property of the antibody, bacteriolysin; if leucocytes are stimulated to phagocytosis, we speak of opsonin.

Experiments have shown that in the interaction an intermediary substance is necessary, without which antigen and antibody are unable to assume any very intimate chemical relations with each other. This third substance, which is present in healthy blood and tissue-fluids, is termed *complement*. Complement is certainly necessary for the neutralisation of toxin with antitoxin; to what extent, or if at all, it is essential for the complete interaction of other forms of antigen with corresponding forms of antibody we do not clearly know.

Now specific therapy has as its object the artificial increase of antibody. Incidentally, it has a secondary object—the maintenance of efficient complement. The artificial production of antibody may be attained in two very different ways: *passive immunity* may be conferred upon the patient with ready-made antibody, or *active immunity* may be produced by stimulation of the patient to manufacture his own antibody on a larger and more efficient scale than he is already doing. Immunised serum derived from animals (e.g., the horse) is most commonly used to confer passive immunity; active immunity is most commonly produced with bacterial vaccines. The two methods may be combined in certain diseases.

---

[1] Abstract of address delivered before Torquay Medical Society.

Available Means of Employing Specific Therapy.

(1) The use of immune serums: (*a*) Antitoxic serums, which chiefly act by the neutralisation of exotoxin formed by bacteria in the body; (*b*) bactericidal serums, which chiefly act by destruction of the bacteria, thereby preventing the increase of endotoxin.

(2) The use of bacterial vaccines, which serve to stimulate the natural mechanism of immunity.

(3) The use of immune serums and vaccines conjointly, either as separate remedies or in the form of sensitised vaccine.

(1) Antiserums: (*a*) Antitoxic serums remain the most strikingly successful, as they are historically the earliest, of all the remedies used in specific therapy, and this applies especially to antidiphtheria serum, less so to antitetanus serum, but the more limited success of the latter remedy is undoubtedly due to the difficulty entailed by the path of infection of the virus rather than to lack of potency in the serum.

(*b*) Bactericidal serums have never yet attained anything like the same degree of success as antitoxic serums, having hitherto lacked a sufficiently rich content of antibody to lead to any uniformly good results. Another difficulty in preparing these serums is connected with the fact that most of the bacteria against which they are manufactured exist in groups, and a serum prepared against one group is by no means specific in respect of antibody for another group. The attempt made in the case of streptococci to produce "multivalent" serum has not proved successful; more hope appears to lie along the line of producing univalent serums against the different groups.

(2) Bacterial vaccines are at present the chief type of immunising substance employed in combating nearly all infections by known micro-organisms possessing powerful endotoxins.

(*a*) The earliest form of vaccine remains the one in most common use—a simple suspension of the killed microbe in normal salt solution. Most bacteriologists appear to kill the bacterial elements by heat; some prefer autolysis—allowing the micro-organism to undergo auto-digestion in the warm incubator after counting. Others, believing that heat interferes with the efficacy of the vaccine, rely upon some such antiseptic as tri-cresol. If we knew exactly what are the initial processes going on in the human body when living microbes invade it, we should be better able to decide how best to prepare the cell-element before we inject it in the form of a vaccine. It seems reasonable to suppose that undue heat and the presence of chemical agents are both to be avoided if the tissue is to digest the bacterial cell and manufacture antibody of use against the living micro-organism.

(*b*) "Sensitised" vaccines ("sero-vaccines") are made by bringing a bacterial emulsion into contact with the appropriate immune serum (e.g., a *Streptococcus pyogenes* is mixed with a univalent *S. pyogenes* serum). The specific antibody in the serum becomes "fixed" by the bacteria, and the combination is termed a "sensitised vaccine." Some authorities doubt whether this sensitisation of vaccines adds to their therapeutic value, and this question is still unsettled.

(*c*) "Live" vaccine has been used by Alcock and others in some cases of gonococcus infection, and in one or two other infections. No special results appear to have been obtained—certainly none which counterbalance the obvious risks that might be run if such a system became generally adopted.

(*d*) "Phylacogens" are prepared with special effort to render the cell-body, which constitutes an essential part of the vaccine material, easily assimilated by the tissues into which it is injected. It is very pertinently argued that valuable time may be lost during the preliminary effort of the tissues to digest or disintegrate the bacterial cell element in order to start the specific interaction resulting in the formation of antibody. An endeavour is therefore made, "partly by appropriate temperatures and partly by chemical agency," to get the bacterial cell structure into solution. During this process there is inevitably added to the solution a certain amount of the exotoxin of the bacteria—an amount depending, no doubt, upon the nature of the medium; but as this medium is invariably fluid the amount of exotoxin cannot be negligible, and it perhaps accounts for the very sharp reaction sometimes seen after the use of this class of remedy. On general principles, as the object in view is not to add more exotoxin to the patient's burden, this must be regarded as a point against the method. To what extent the endotoxin of the bacterial cell goes into solution it is not possible to say, because unfortunately we have no chemical means of measuring this substance; but it seems fairly certain that in the preparation of phylacogens a more successful effort has been made in this direction than hitherto.

(*e*) The most modern of all remedies of the bacterial vaccine type are the detoxicated vaccines. These we owe to Dr. David Thomson, who argues that it is an advantage to get rid of the endotoxin of the bacterial cell, if that were possible, partly because of the known difficulty of producing anti-endotoxin experimentally by the injection of the whole cell element and partly because, with the endotoxin removed, it would be possible to use much larger doses of the vaccine, and thus obtain proportionately larger responses in the way of cell-destroying antibody. Thomson considers that he has devised a means of removing the endotoxin without, at the same time, altering the nature of the bacterial cell substance, which is then left for purposes of inoculation. As yet it is too early to judge of the value of these detoxicated vaccines.

Choice of Remedies.

The choice of the particular remedy to be employed in any case of infective disease depends upon (*a*) the nature of the infection, (*b*) whether it is local or general, (*c*) its acuteness or chronicity, and (*d*) the stage at which the infection has arrived. Let it be noted that there are two important differences between serums and vaccines arising out of their mode of action as already outlined: (1) Immune serums act rapidly, but their action is transient; vaccines act slowly, but their action is more prolonged; (2) immune serums supply important substances that are lacking in the body, and do not require much active response on the part of the tissues in order to produce their effects; vaccines depend for their action upon a latent power in the tissues of producing antibody when specifically stimulated to do so. It may be said that the more acute and generalised the disease-process and the more ill the patient, the more likely is immune serum to prove efficacious; the more chronic and localised the disease-process and the less ill the patient, the more likely is a suitable vaccine to do good. It is often advisable to begin the treatment of a severe case of infection by immediate and liberal use of an appropriate serum, and to follow up any advantage thus gained by inoculation with a vaccine prepared in the meantime.

Results and the Future.

The fact that so many remedies are available for inducing immunity stimulation in the patient proves how far we still are from standard measures of treatment and results showing any sort of uniformity. There are difficulties in connexion with immunity research; no subject calls for greater imagination combined with meticulous technique. There are difficulties in connexion with the practical use of the substances offered for exploitation to the practitioner. What argument can be more difficult or more complex than the therapeutic argument? It is full of pitfalls and possible fallacies. Patients get well at times in spite of our treatment, and they die at other times when the remedies seem to possess the hall-mark of precision. *Post hoc* and *propter hoc* dog us wherever we go, and properly to assess the part played by any remedy in the recovery of the patient is easy only to the ignorant.

It will not be surprising if some of the present clumsy technique is shortly superseded by more exact methods of preparation of immunising substances. The war, wasteful of time and brains as well as of human life and money, has no doubt delayed development; we must now exploit the remedies that are at our disposal as well as we can—not, by the way, adding to them in an amateurish fashion of our own.

We should understand what we are trying to do, and, so far as is possible, the nature of the materials with which we work. These principles of practice are not only essential to our own development, they are part of the duty which we owe to our patients. The preservation of mental clarity is a most important asset in the practitioner's attitude towards these things. Once he loses it he no longer controls his remedies: they control him.

MEDICAL AND SANITARY REFORMS IN MESOPOTAMIA.

A "Review of the Civil Administration of Mesopotamia," is the title of the paper recently presented to Parliament, giving an account of the civil administration during the British military occupation down to the summer of 1920, when, a mandate for Mesopotamia having been accepted by Great Britain, steps were being taken for the early establishment of an Arab Government. The preparation of the Report was entrusted by the Acting Civil Commissioner to Miss Gertrude Bell, C.B.E., Assistant Political Officer, Baghdad, who speaks Arabic fluently, is noted as a traveller and explorer in Asiatic Turkey, and has by her work and writings gained the Founder's Medal of the Royal Geographical Society. Subjoined is the substance of those portions of her report which relate to medical and sanitary matters:—

> Closely connected, from one aspect, with the land—that is to say, with its capacity for production—is the provision of medical and sanitary facilities for the civil population. If man-power is the primary asset in the national economy of every community, in Mesopotamia the problems connected with its preservation and increase present themselves in an acute form. The vast development of which the country is capable waits upon a substantial addition to the number of its inhabitants. . . . The population of the 'Iraq, though scanty, is prolific, but the absence of medical

arrangements and an all-prevailing ignorance of the laws of health and sanitation have combined to keep it down. If infant mortality were arrested and the children given a better prospect of reaching adult life it might not improbably be doubled in the next 30 or 40 years.

Public Health during the Military Occupation and in the Transition to a Peace Footing.

From a military point of view care of public health and the sanitation of the towns were necessary precautions if the troops were to be kept free from disease. A civil dispensary was opened in Basrah immediately after the occupation, while the Deputy Military Governors took steps to secure the cleanliness of the town. A civil hospital was started in 1915 and additional dispensaries opened in 'Ashar. A civil surgeon superintended these establishments, and was put in charge of sanitary arrangements in Basrah, and an army medical officer controlled the sanitation of 'Ashar. The sanitation of the gaol and the health of prisoners received careful attention. Lunatics could not be provided for locally and were sent to India for treatment. The attendance at the dispensaries and hospitals was greater than had been expected. The people accepted inoculation and other precautions against plague, and were eager for vaccination. After the occupation of 'Amarah a hospital and dispensary were opened there under a British army doctor, and they proved as popular as in Basrah. Similarly at Nasiriyah the services of a military doctor were lent to the civil hospital and dispensary.

After giving credit for the zeal and tact of the medical officers and praising the Indian dispensaries and medical staff, the Report goes on to state that during 1916 there was a notable advance in the sanitation of the towns, and that infections diseases were checked. At Sug, owing to shortage of medical staff regular work was not started till 1917. The absence of a dispensary was regarded by the inhabitants as a grievance, though under the Turkish regime no such institution would have been dreamed of. Apart from their special use the hospitals made a most valuable form of propaganda work.

During the process of demobilisation it was necessary to assure the continuance of adequate health and medical services when the military authorities could no longer give assistance. By the middle of 1918 there was a civilian hospital or dispensary in each military station of any importance with either a civilian surgeon in charge or a military officer who undertook civilian work in addition to his military duties with the help of an assistant, usually an Indian subassistant surgeon. Native and Turkish doctors were also employed wherever possible, though, generally speaking, their sphere of usefulness was limited by lack of training.

Coördination of Civil Institutions.

The civil institutions had not been coördinated, owing to the absence of any central organisation, but in August, 1918, this was remedied by the appointment of a Civil Deputy Assistant Director of Medical Services, who worked in the office of the Military Director of Medical Services and acted as a liaison officer. In February, 1919, he became administrative head of the civil medical department, and in March, with the more complete organisation of the health department, he was appointed Secretary for Health. There were then in existence some 50 civil hospitals and dispensaries, three-quarters of which were run by a civil staff, though in nine of these supervision was undertaken by military medical officers. Arrangements had been made with the base medical stores before the end of 1918 to maintain sufficient supplies to meet all the requirements of the civil medical service for the year 1919, and the nucleus of a civil medical depôt had been formed in Baghdad.

By arrangement with the Red Cross Society, which demobilised in March, 1919, this depôt had the first option on all the Red Cross stock in the country. As regards sanitary work, locally trained inspectors and gangs replaced sanitary sections in the towns in which they had been employed, and the care of public health began to pass everywhere into civil charge. It includes the inspection of prisons, markets, noxious trades, and slaughter-houses, the provision of chlorinated water, measures to ensure general cleanliness, and the destruction of rats, mosquitoes, and flies. The civil surgeon of a provincial town, who is also health officer, is overwhelmed with administrative work in addition to his medical work, and it is only by unceasing labour that he can accomplish his task. The devotion shown by the officers of the Medical Service, and their tact and skill in handling the native population, have been beyond praise.

Hospitals and their Staff.

Immediate steps were taken to enlist what medical personnel was available in Mesopotamia and to recruit at home such additional staff as was required, with the result that it has been possible to supply urgent needs. There are now hospitals in Baghdad, Basrah, and Mosul, nursing sisters tend the civil hospitals, and both Baghdad and Mosul have hospitals set apart for women and children. The women's hospital in Baghdad has an interesting history. It is lodged in an excellent building, which was in Turkish times the civil hospital of the town. A small staff of French nuns had been employed by the Ottoman Government as nurses; they had endeared themselves to the people, and their community had earned our lasting gratitude by the services they had rendered to British prisoners during the war. It was decided to ask the nuns to continue to serve in the hospital under the new arrangements, and employment was offered to an additional number of trained sisters who are being brought from France. To see these admirable women carrying on their work with every advantage that the British Medical Service can supply carries conviction that all is not wrong with the world.

In Basrah, where the house used as a civil hospital is not suitable, a new building will be erected out of funds subscribed voluntarily by the inhabitants in memory of General Maude. Nasiriyah also boasts a Maude Memorial Hospital. The British and French nursing sisters undertake the training of native girls, not only to serve in the hospitals, but also with the object of creating a body of trained nurses to work among the native population. The better-class women of Baghdad readily admit the need of trained midwives, for, as they observe, the existing midwives bring disease instead of combating it. ...... Depôts for medical stores have been instituted both at Basrah and at Baghdad, and in the latter place, besides the women's hospital, there is a civil hospital for men, an isolation hospital, an X ray institute taken over from the army, a dental institute, two dispensaries, a nursing home for officers and their wives, and a venereal hospital for women. The terrible scourge of venereal disease receives special attention at other centres.

Prevention of Infectious Diseases.

The prevention of infectious diseases is being dealt with effectually, perhaps, the most gratifying achievement having been the checking of an epidemic of plague in 1919 by a whole-hearted resort on the part of the local population, male and female, to inoculation with plague vaccine. Over 80,000 people were inoculated. A vaccine lymph depôt, started by the military authorities at 'Amarah, ensures a supply of calf vaccine throughout the occupied territories. In the Mosul Wilayat the most serious problem which confronts us is the universal presence in the hills of malaria of a violent type. The condition of the villages is deplorable: some, indeed, are reported to be uninhabitable. In most areas occupied or traversed by our troops careful malarial surveys by specialist officers have been made, and it is hoped soon to preserve these records by making them available in condensed printed form so that they be accessible to all concerned.

Danger of infectious disease is notably increased by the influx of pilgrims to the Shi'ah shrines. During the war the pilgrimage was necessarily intermitted; permission to renew it was given in 1919, and exceptionally large numbers availed themselves of it. An average of 7000 pilgrims a month passed through the frontier town of Khanigin. No attempt has been made to imitate the Turkish quarantine arrangements, which were as burdensome as they were inefficient, but careful measures are taken to ensure the cleanliness of Khanigin, and a dispensary for the treatment of pilgrims will be opened at railhead. In the holy towns the pilgrims entail much additional sanitary work, but the precautions which have been taken cannot yet be considered to suffice.

Quarantine for the Dead.

The Report concludes with some account of the measures taken by the Health Department for the prevention of infection by the dead. Bodies brought for burial to Karbala and Najaf are quarantined under regulations which have been drawn up by an international commission controlled through the International Quarantine Board, but the control of both corpse and pilgrim traffic are difficult and delicate matters. It is hoped that in the future the subject may receive consideration by a committee consisting of the various interests concerned—transport, political, and medical. Finally, the Report says ;—

> It may be said with assurance that in few directions has more rapid progress been made since the occupation than in the case of public health. In Baghdad, Basrah, and Mosul the increase in the number of beds is as notable as is the increased efficiency of the present hospitals compared with those that existed in Turkish timse. But it is, perhaps, in the provinces that the greatest change has been effected. Provincial hospitals and dispensaries were rare under the Ottoman regime, and even where they were to be found they were of little value. At Nasiriyah, for example, the staff consisted of a single doctor, who frequently shut the dispensary and went away, leaving all work at a standstill. The Turks made no attempt to win the confidence of the tribesmen, and the bulk of the population was thus left without medical aid of any kind. In the villages sanitary precautions were non-existent and in the provincial towns they were grossly insufficient.

The efforts of political officers and civil surgeons have brought about improvements which are indeed remarkable.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

Sir Alfred Pearce Gould presided at the annual general meeting of this Society, held on May 18th, at 11, Chandos-street, London, W. The report for 1920 showed that during the year 11 new members had been elected and 6 lost owing to death and resignation. The Society consists at the present time of one honorary, 163 life, and 137 ordinary members, making a total of 301. The income from investments amounted to £4682 odd, £373 received from subscriptions and donations, and the working expenses were £299. During the year two widows came upon the funds and three died. The sum of £4584 was distributed among the annuitants, comprising 52 widows and 6 orphans. Membership of the Society, which is one of the richest of its kind in the United Kingdom, is open to any registered medical practitioner who at the time of his election is resident within a twenty-mile radius of Charing Cross. Relief is only granted to the necessitous widows and orphans of deceased members of three years' standing and of life members. At the present time the widow who has an income of not more than £100 a year receives a grant of £50 per annum, and each orphan, up to the age of 16, a grant of £43 per annum. In speaking to the report the acting treasurer drew attention to the fact that the working expenses were about 5 per cent. of the total income. The next election of members will be on July 6th.

G. Ll. J. asks for suggestions in treating a case of acute nephritis following Henoch's purpura in a boy of 13. The febrile period lasted six weeks and left the urine loaded with albumin, blood, and epithelial casts.

The Relation of HEART DISEASE AND PREGNANCY.

By Sir JAMES MACKENZIE, M.D. Edin., F.R.S.,
DIRECTOR OF ST. ANDREWS CLINICAL INSTITUTE.

IN FOUR SECTIONS—SECTION I.

Introduction.

There are few subjects in medicine of which an accurate knowledge is more urgently required than that of a woman's fitness for child-bearing. That a great strain is thrown upon the maternal heart during pregnancy and labour is well known. It is a matter of experience, too, that the pregnant state may throw more work on the heart than it can bear, with the result that the mother's life is lost, or her health irreparably impaired. The child, too, often dies. These disastrous happenings surround a natural process with dread and mystery, for the dread is aggravated by the fact that the source of danger is not clearly realised. As a result, all sorts of signs are looked upon with suspicion—signs innocent as well as signs grave. Needless to say, this obscurity does a great deal of harm. Many women are subjected to unnecessary alarms and restrictions when pregnant; others have to suppress the natural desire of motherhood; while connubial relations are often disturbed by warnings and hints of dangers which may never arise.

Defect in Medical Knowledge.

This unsatisfactory state of affairs is entirely dependent on a defect in medical knowledge which it is quite possible to remedy. That the matter is not worse is in a measure due to the fact that the vast majority of women, especially women of the working-classes, never have their hearts examined. Were they systematically examined, abnormal signs would be discovered in many instances; the significance of these signs would not be understood; grave doubts would be aroused. Thus, many who have passed unscathed through the pregnant state would have been unnecessarily frightened and alarmed.

When we seek for an explanation of our ignorance on this subject we find that it is due to the fact that medical knowledge has not advanced far enough to enable us to understand the meaning and significance of certain physical signs. Moreover, we find a new difficulty when we come to ask ourselves in what way our lack of knowledge can be made good. Gradually it is forced on our minds that if we would understand clearly defects and their origins we must go back to the beginning and consider the way in which, at present, the subject-matter of these chapters is investigated and taught.

The teaching of disease of the heart comes within the province of the physician. When, however, one comes to estimate the opportunities the physician has for dealing with the relation of heart disease to pregnancy, one soon discovers that his practice never brings him into contact with pregnant women except when one of these latter is referred to him for an opinion. On these occasions it frequently happens that, instead of frankly recognising that his experience does not justify him in claiming a knowledge of the subject, he gives a prognosis of the "guarded" type. He says in effect: "The patient may undergo pregnancy safely; on the other hand, there is a possibility that she may not." The effect of this is that the patient is left with a vague notion that some dread fate hangs over her head. In other instances the physician "plays for safety," and forbids the pregnancy, yet these patients may be perfectly capable, in many cases, of undestaking it.

The obstetric physician, if we may judge from modern text-books, has never taken the trouble to understand the elements of cardiology; in consequence he continues to pursue his enigmatical methods. While the advances in cardiology are barely mentioned in books on general medicine, they are not dealt with in books on obstetrics. In the recent text-books on this latter subject which I have read there is not the slightest indication that any advance has been made in the study of the heart during the last forty or fifty years—the writers apparently being unconscious of the revolutionary changes which have taken place in our knowledge of this organ in this period of time.

I am emphasising this point for reasons which have only an indirect bearing on the matter in hand. I wish my reader to visualise clearly the methods peculiar to medical investigation. Pregnancy is not the only condition which is shrouded in darkness. There are a great many other questions of a similar kind which are an integral part of the practice of medicine and which await inquiry. No progress, I believe, can be made in regard to them till it is understood how medical investigations should be conducted. The matter of heart disease and pregnancy serves thus as an illustration of a wider difficulty. It shows, if we will but learn the lesson, how completely our present-day method of medical research fails of its purpose. It is my aim to indicate the nature of this failure, and to explain in what manner I conceive that success may be attained.

Personal Experiences.

My attention was early directed to the subject of Heart Disease and Pregnancy by a tragic experience which occurred soon after my entrance into general practice, about forty years ago. I attended a young woman, 35 years of age, for a miscarriage at the third month of her first pregnancy. I discovered then that she had a presystolic murmur; so far as my investigation of the condition went, there was nothing more the matter with the heart. I had a vague notion that mitral stenosis was a serious embarrassment to the heart in pregnancy, but of the source of danger and its nature I had no knowledge. The woman left my neighbourhood for a year, at the end of which time she returned to her father's house, seven months pregnant, and with a considerable œdema of the legs. This œdema increased until, when labour set in at full time, she was much swollen not only in the legs, but in the abdomen. The external genitals were so œdematous that an examination per vaginam could be carried out only with difficulty. As the labour proceeded little progress was made; the suffering was very great, and there was marked distress in breathing. The patient had to lie propped up in bed, a position which rendered the use of instruments impossible. Moreover, so profound was the sense of suffocation that attempts to give chloroform were resisted. Two practitioners of much experience saw her, but after many hours of suffering she died undelivered, from extreme exhaustion.

I had, at that time, a fairly large midwifery practice, and, on several occasions during the next few years, I had some rather trying experiences in attendance on women with heart trouble, though no other case proceeded to such a disastrous ending. I noticed, however, that in a number of patients with damaged hearts the pregnancy further impaired the functional efficiency of that organ. The importance of this being thus forced upon me, I read carefully all the available literature. This, indeed, confirmed the view I had formed as to the danger in mitral stenosis, but gave me no enlightenment about the risks in other forms of heart affection. There were many vague hints of the evils arising from valve lesions, but of sufficiently definite information to enable me to recognise which types of these lesions were to be feared there was none. Even the changes occurring in the normal heart during pregnancy were very imperfectly described.

State of Knowledge of Cardiac Phenomena.

I made a note of the results of my reading, and propose to give the gist of it here as a kind of review of the state of knowledge of cardiac abnormalities prevalent forty years ago. That this may be found strangely apposite to-day by certain of my readers will only show, I fear, that the attitude of the profession of those early times is still the attitude of the bulk of teachers and authors. Indeed it seems to me, as I turn back to these old pages, that the trend of modern medicine, both in teaching and investigation, is to render the solution of such problems as the relation of pregnancy and heart disease impossible. Before the discovery of auscultation and the use of the stethoscope, about 100 years ago, experienced physicians estimated the state of the heart by its manifest functional efficiency; and in reading the authors before that date, I find that many of the views which I have arrived at were anticipated by them. There is no doubt in my mind that the line pursued by those physicians was sounder than that which has been followed since the introduction of mechanical devices. The coming of the stethoscope was the beginning of a method in clinical research which has greatly hampered the practice of medicine, in that the introduction of mechanical methods has led to a confusion as to the kind of knowledge which these methods are capable of affording. This criticism applies not only to the stethoscope and its various modifications, but to all the other instruments which have since been employed in the examination of the patient. I need mention only the sphygmograph, polygraph, electro-cardiograph, and blood-pressure instruments.

The discovery of the sounds of the heart and the various modifications of these sounds was followed by a period in which a great deal of time was spent on auscultation and on the discussion of the phenomena revealed by it. At first the cause of the cardiac sounds was not clear; a long series of observations, experimental and clinical, was therefore undertaken, to find out the manner in which the sounds were produced. I do not dispute that a great deal of valuable knowledge was thus accumulated.

One unfortunate consequence of this concentration upon the new method, however, was to give it a preponderating importance in the examination of the heart, and to minimise the value of the study of other phenomena, with the result that unjustified conclusions were drawn from mere modifications of the sounds. This, as has been indicated, was an error inherent in the view taken, at that time, of the possibilities of the new instrument. The physician who detected an abnormal sign supposed that in detecting it he had obtained information of a sort hitherto only obtainable by a test of functional capacity. He believed that he had gained knowledge entitling him to make a prognosis without the labour of determining how far the patient's activities were already curtailed. What he failed to see was that so long as he did not know the mechanism of production of the abnormal sound, nor the after-histories of people who might have this abnormality, he could not properly base conclusions on its presence. Thus, in reading the early literature of heart affections, since the introduction of the stethoscope, we find a grave significance attached to the presence of a bruit, at a time when the cause of the bruit was unknown and the kind of information which it conveyed was not understood. I have sought for an explanation of this rather astonishing state of affairs. I find it, I think, in the probability that a physician, examining dying patients in whom a bruit was present, would attribute the failure of the heart to the cause of the bruit. That this is the correct explanation is rendered more likely because we find similar reasoning following the discovery of a sign by any new method. Thus, to-day, physicians and "heart specialists" may be observed attributing serious significance to peculiarities detected in graphic or electro-cardiographic records or in blood-pressure readings before they understand the nature of the signs on which their gloomy forebodings are based.

I dwell on this to draw attention to the fact that medical knowledge has not even yet advanced so far as to enable investigators to understand the principles which should guide them in recognising the significance of an abnormal sign. They do not know how to apply their observations in practice, nor what steps to take to obtain an estimate of their significance. This statement may seem to be an exaggeration; if, however, the reader will consider the methods, to be described later, which I was compelled to employ in order to find out the significance of a symptom, he will, I think, realise not only that a defect in knowledge existed, but also how it came to exist; and why it is still with us.

The hasty conclusions formed by the early observers in regard to the significance of murmurs have hung like a mill-stone round the necks of the profession; to-day these conclusions mislead the vast majority of doctors, and cause much unnecessary trouble and injury to people in many walks of life.

THE NORMAL CHANGES IN THE MATERNAL CIRCULATION DURING PREGNANCY, CONFINEMENT, AND THE PUERPERIUM.

Methods of Investigation.

In my endeavour to find out wherein lies the danger of pregnancy to women with heart disease, I experienced most difficulty in determining how to set about such an inquiry. The study of patients with damaged hearts proved fruitless and misleading, for I was not able to tell the significance of some of the symptoms. I had already supposed certain of these latter to be abnormal and of grave significance, on grounds which I was coming to recognise were insufficient. At last I realised that it was necessary for me to understand the phenomena which occur in healthy women if I was to form a clear idea of the changes taking place in consequence of the accommodation of the circulatory system to increased work.

I began, therefore, to observe women during their confinements, noting all the signs which I took to be departures from the normal, and also those which occurred as a consequence of the straining during the labour. I soon found quite a number of changes; for example, modification of the sounds, murmurs, irregularities, displacement of the apex beat outwards to the left, some duskiness of the countenance, and so on. Some of these signs were modified or disappeared during the puerperium. I was at a loss to explain their presence or their significance, and I saw that the subject required far more thorough investigation. I recognised that it would be necessary to watch the onset of these signs, and the conditions or factors which caused them; then, it would be necessary to watch patients for a long time after their confinements to see if the signs disappeared or remained to give rise to trouble in the future. This latter part of the problem was one of extreme difficulty. For it was not only necessary to note the progress of the patient, but also to find an intelligent method of estimating the significance of the changes which might be observed.

In the routine of my work as a general practitioner, I had opportunities of seeing women before they became pregnant. I made careful notes of the state of the heart and circulation in such of these as I expected would become pregnant. When they consulted me afterwards for early troubles, such as sickness and vomiting, I examined their hearts at intervals. Further, I examined those who bespoke my service for their confinements, and kept them under observation till labour began. As time went on, I found that one sign after another required particular observation, and so I had to adopt special methods to obtain the information I desired. Thus I found œdema of the lungs to be a very important matter in heart failure, and its relation to the pregnant state had to be specially considered. I found, too, that the embarrassment of the circulation increased during the last months of pregnancy, and that a number of new symptoms appeared then; for example, murmurs, irregularities, and pulsation of the veins of the neck. It was necessary to know exactly when such changes began; so I used to ask the patients to stay in bed on certain days till I had visited them. The different points were carefully noted. Finally, the significance of these signs, as they were related to the heart's efficiency, had to be considered. This led to an inquiry, extending over many years, which is not yet complete.

I will deal specifically with the more important symptoms in later chapters; here I propose to summarise the results of the alterations which occur in healthy people.

CHANGES DURING THE EARLY MONTHS OF PREGNANCY.

Practically no changes in the circulation could be detected in the early months of pregnancy. Sometimes sickness confused the picture, bringing in its train exhaustion, and variations of the pulse rate, but as time went on these disappeared.

Limitation of Response to Effort.

Towards the sixth month the response to effort began to be restricted, i.e. breathlessness appeared after an amount of exertion which had hitherto been accomplished in comfort. As a rule this never became extreme, and the woman was able to attend to her household duties: she felt the breathlessness chiefly on going upstairs.

Effect of Increase in Size of Uterus.

About the seventh month the uterine tumour altered the shape of the chest—widening it out so that the circumference gradually increased. The chest was measured immediately under the breasts and, as full time approached, the circumference increased considerably in some cases. Immediately after delivery the circumference diminished, and day by day it decreased till some weeks after confinement it had returned to normal.

The following are a few examples:

		Inches.
CASE 1.		
At full time	.. ..	28
Immediately after birth of child	.. ..	25¾
Four days after birth of child	.. ..	21½
CASE 2.		
At full time	.. ..	26½
Immediately after birth of child	.. ..	26
Seven days after birth of child	.. ..	26
CASE 3.		
At full time	.. ..	29
Immediately after birth of child	.. ..	28½
One day after birth of child	.. ..	25½
Three weeks after birth of child	.. ..	23½

Displacement of the Heart.

Coincident with the change in the chest circumference the heart was frequently displaced until the apex beat was pushed out one inch beyond the left nipple line, and upwards to the fourth interspace. After labour the heart gradually swung back into its normal position.

Hypertrophy of the Left Ventricle.

It is well to bear this normal displacement in mind. For a long time it has been held that the left ventricle hypertrophies during pregnancy and undergoes some sort of involution after confinement. The evidence for this view has been based chiefly on theoretic grounds, on some very imperfect post-mortem observations, and on the displacement of the apex. Further, the safety of chloroform anæsthesia during pregnancy has been attributed to the same circumstance. No evidence of hypertrophy could be perceived.

Stasis of the Lung.

Accompanying this widening of the chest, there is a tendency for stasis to occur at the bases of the lungs. This will be dealt with in speaking of the failure of the right heart. In order to estimate the factors which embarrass the right heart, the lessened effect of the movements of respiration had to be considered. I found that normally there was a tendency to stasis even in healthy women when pregnant. In the periodic examination of pregnant women I found that a few of these, after lying in bed all night, had crepitations at one or both bases. These crepitations disappeared after one or two deep breaths, and were never present during labour. They returned for a few days after the confinement. The meaning and significance of this sign will be discussed later.

Venous Stasis.

A variety of phenomena appeared on the venous side of the circulation. In a number of patients the veins of the legs became swollen and varicose—in some there was considerable swelling and varicosity of the veins of the thigh, and of the vulva. Hæmorrhoids were frequent. The cause of these changes is not clear to me. I lean to the view that they are the result of actual pressure on the veins in the pelvic or abdominal cavities. Some writers, however, say that these signs may appear at a stage so early that pressure is out of the question. I had not myself observed them at such an early stage. There is, no doubt, a marked change in the peripheral vascular system in the smaller arteries and veins, which is made evident particularly in the breasts. The mammary artery, usually imperceptible, becomes dilated, and probably the arteries generally dilate to a slight extent, though this is not capable of measurement. One can infer so much from the fact that many women become fatter during pregnancy. There is perhaps also an increase in the quantity of blood.

I find that some writers attribute the hæmorrhoids and varicosities of the vulva to back-pressure from the heart. That is an error, of little importance so far as this matter is concerned, but one which must be pointed out, as it misleads when we are dealing with heart failure. The idea that the heart fails by an engorgement affecting one chamber after another has long held the field. We are invited to picture regurgitation from one orifice after another until the right auricle and ventricle throw blood back into the venous system, causing the appearance of venous stasis, varicosities, and dropsy. While no doubt there is a little truth in the idea, it can be laid down that such an effect of heart failure has only a very slight influence and is not the cause of the phenomena attributed to it. I have seen many people die slowly of heart failure in whom none of these signs appeared. I have seen the right auricle and ventricle throw such quantities of blood back that the liver was distended and pulsated at each systole; yet there was neither venous stasis nor dropsy in the legs. Experience shows that varicose veins are frequently present in people with perfectly healthy and efficient hearts.

Pulsation in the Jugular Veins.

Another symptom usually, but erroneously, considered to be the result of this back-pressure is pulsation in the veins of the neck. During a systematic inquiry into the signs exhibited by the circulatory system my attention was arrested by the movements in the veins of the neck. At the time when I began the inquiry very little attention had been devoted to this subject. The pulsations indeed had been recognised, and graphic records of them had been obtained, but the nature of the movements taking place and their significance were not understood.

Among healthy women during pregnancy I found that these pulsations vary in an extraordinary way. They are present at one time, and absent at other times; sometimes they are small and bare' perceptible (Fig. 1), then again they become of great size (Fig. 2). The records of many patients showed that pulsations were often quite distinct before pregnancy. They might remain unaltered during the whole period till labour set in. During labour they practically always disappeared, but returned in a day or two after delivery, sometimes attaining a great size. Thus in the case from whom Figs. 1 and 2 were taken there was no jugular pulse during the labour, a faint pulse next day (Fig. 1), and a large pulse on the second day (Fig. 2). I attempted to correlate these variations with coincident changes in the heart—seeking for evidences in the size of the organ, in its sounds, or in its functional efficiency, but I failed to find any relation. I thought that the increased size of the venous pulse might indicate a dilatation of the right heart, but I found the increase taking place and the heart remaining normal in size, with no alteration of the cardiac sounds.

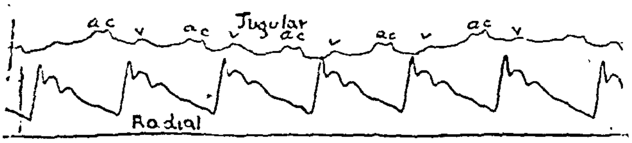

FIG. 1.—Tracings of the jugular and radial pulses the day after the confinement, showing only a faint movement in the jugular tracing.

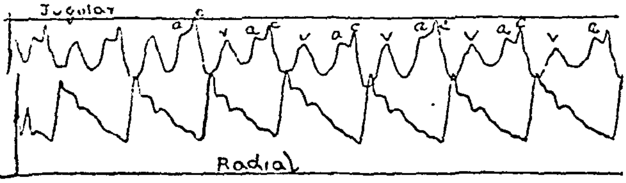

FIG. 2.—Tracings of the jugular and radial pulses the second day after confinement, showing a large movement in the jugular tracing.

The disappearance of the venous pulse during labour seemed capable of a reasonable explanation. A false view of the effect of effort upon the heart has long been held—the view that the healthy heart dilates with effort. More careful observation reveals the fact that, instead of dilating, the healthy heart actually becomes smaller on effort. It will be realised, if thought is given to the subject, that this is to be expected. When effort is made dilatation takes place in the peripheral vessels. The result is that during effort there is, in the peripheral vessels, a relatively greater amount of blood than is present in them when the body is at rest. As the size of the heart depends partly on the quantity of its blood-content, with a diminution of the blood during effort, the size naturally becomes smaller.

The right auricle and the veins leading to it act as a reservoir to the ventricle. The pressure in the veins and auricle is never of itself able to distend the ventricle and cause dilatation: so that, when there is a free return of blood from the periphery, the jugular vein is never quite empty. The emptying and filling of the auricle and ventricle cause a variation in the quantity of blood in the jugular vein, and it is this which we recognise as the pulsations referred to, and which we can graphically record (Fig. 2). When, therefore, a larger quantity of blood is contained in the peripheral vessels, the jugular vein does not receive a sufficient amount for the movements occurring in it to be perceived. After the effort has ceased, however, the returning blood increases to such an extent that the reservoir becomes filled. The movements are then again visible.

In order to comprehend the relation of these pulsations to heart failure I watched patients with a jugular pulse for many years, noting the effects of effort and illness—particularly febrile illness. In rare cases I discovered great pulsation in the veins with certain forms of heart failure—but, on the whole, I found that neither the presence nor the absence of pulsation was of any use in estimating the efficiency of the heart. In those rare cases to which I have referred there were present other signs which gave a surer indication.

Where, on the other hand, the study of the jugular pulse became of the greatest value was in unravelling the mechanism of cardiac irregularities. By observing the changes in the jugular pulse, I discovered a method of differentiating between the waves produced and of relating them to their causes in the heart itself. This matter will be referred to in dealing with Heart Irregularities.

Dropsy.

The mechanism by which dropsy is produced is still one of the most obscure matters in medicine. My notes of cases of pregnancy show that in healthy women, at this time, swelling of the legs was far from infrequent. It was usually slight, but sometimes became very considerable. As it tended to get worse towards the end of the pregnancy, and as there were no accompanying changes in the heart, I attributed it to the pressure of the uterus on the veins. At all events, the women went through their confinements quite well, lived for years afterwards, and bore other children. Even those women who also had albumin in the urine did well. (I am not referring to cases of albuminuria which ended in uræmia. I had, like every other general practitioner, experience of these. My opportunities, however, were too restricted to enable me to get a full knowledge of the significance of this sign, which, be it said, still awaits elucidation.)

Cyanosis.

During labour, in many patients, the face becomes tinged and dusky, while the lips become of a dark red. I made a great many observations on the capillary circulation in this connexion, but nothing definite was elicited.

In many women systolic murmurs and irregularities appeared and disappeared. These will be dealt with subsequently.

CHANGES IN THE DISEASED HEART IN PREGNANCY.

Abnormal Signs appearing during Pregnancy.

I had many patients who showed abnormal circulatory signs. Let me say at once that the great majority of these passed through the pregnant state, confinement, and puerperium with no trouble. Thus, some cases of mitral stenosis did not seem to suffer in the least, while others suffered severely. Cases of irregularity showed the same variation—the great majority passing safely through, a few revealing signs of heart failure. Cases, again, in which the heart was weakened from other causes, but where there were no abnormal physical signs such as murmurs or irregularity, bore the pregnancy well and seemed little the worse afterwards. These latter were usually breathless and the victims of præcordial pain.

The Interpretation of Abnormal Signs.

At the time when I was making these observations, the results seemed terribly bewildering; they did not enable me to recognise where the danger lay—which was the object of my research—and their variations seemed without principle. I had forced upon me the urgent necessity of a more thorough knowledge of the fundamental nature of abnormal signs, the mechanism of their production, and the bearing of their causes on the heart's efficiency, especially under stress. To obtain this knowledge I began a new, long investigation into the meaning of all manner of cardiac symptoms. This investigation has occupied me for many years; it took me away from the study of heart disease and pregnancy.

I missed, therefore, the opportunity of studying directly heart failure in pregnancy in large numbers of women. On the other hand, I obtained some knowledge of the fundamental principles underlying the production of heart failure. The application of these principles to the cases of heart disease complicating pregnancy which I have since encountered has, I believe, demonstrated their usefulness. It has demonstrated also the value of the type of observation of which I am speaking. I had, as a consultant in London, a great many women referred to me by doctors who were anxious to know whether they were fit for child-bearing or whether, pregnancy having been incurred, there was danger. In these instances I made use of the principles I am about to describe. They guided me to an opinion. The results fully justified the faith I had learned to repose in them.

The Differentiation of Abnormal Signs.

In order to acquire a knowledge of the source of danger in heart disease complicated by pregnancy, I had to get a clear view of the heart's work, how this organ accomplished its work, and what were the signs when it failed to perform its duties in an efficient manner. I conceived that the key to this problem was heart failure. I searched the literature of the subject, but except when heart failure had reached an extreme degree, giving rise to dropsy, dyspnœa, and enlarged liver (sometimes spoken of as the "cardinal signs of heart failure"), little attention seemed to have been devoted to it. Indeed, so confused were the descriptions that no certain differentiation appeared to have been attempted between the phenomena of heart failure and those of other accompanying, but merely incidental, states. Nor was there any clearer distinction to be found between signs which indicated disease and signs in their nature physiological, or so little pathological as to be of no prognostic significance. Thus, it was recognised that murmurs or irregularities might in many cases be indicative of nothing serious. It was stated that there were other murmurs and irregularities which were of grave significance. What was not stated was how one might differentiate the serious from the trivial, the important from the merely incidental.

In the case of irregularities matters were in worse plight. Here there was no differentiation at all. I had not gone far into this subject before I found that progress was impossible unless and until I should be able to distinguish one form of irregularity from another.

The Significance of Abnormal Signs.

Even when, at last, I had succeeded in recognising clearly the different forms of irregularity there remained the important question: "What bearing does their presence have on the patient's future?" This question applied, as I saw, with equal force to the subject of murmurs. Attempts to answer it had in this latter instance been made, but they had not succeeded, for the matter was left in a very vague and indefinite state.

The question is one of such urgent moment to the rational practice of medicine that only the slightest consideration is required to convince anyone that a solution of it must be obtained. Nevertheless, I repeat, no really systematic endeavour to find a solution had been made. The prognostic significance of such common signs as murmurs and irregularities was by no means understood. The somewhat rule-of-thumb procedure which led to the vague notions then prevalent hindered as often as it helped.

The Misunderstanding of Prognosis.

When I reflect now upon the steps I took to obtain this knowledge I can understand to some extent why it had been neglected. Prognosis, at first sight, seems an easy business as compared with diagnosis. Moreover doctors, as students, have their prognosis given to them ready-made in terms of diagnosis. They are told, for example, that a murmur means a damaged heart. As soon as they are out of school they are placed in positions which impose the necessity of making prognoses. If they enter the army or navy they are at once put to the duty of examining recruits, a matter requiring a knowledge of prognosis. If they become examiners for life insurance the same knowledge is essential to the performance of their duties. In every field of medicine indeed where an opinion as to the future of an individual is concerned, the necessity of assessing the prognostic value of signs and symptoms is necessary. Thus the young doctor begins at once to act upon what he was taught. He accepts the ready-made prognosis and gets into the habit of using it. He says that "a murmur means a damaged heart," and does not doubt that he is right. Thus prognosis seems to be a matter of the greatest simplicity once a diagnosis of signs has been arrived at. The vast and vital difference between the sign itself and the nature and significance of it is overlooked or forgotten.

It is scarcely necessary to dwell upon the importance of a true knowledge of prognosis to a doctor who has to determine whether a woman is or is not fit for child-bearing.

Method of Arriving at Prognosis.

In my own inquiry into prognosis in heart affections I made many false starts before I recognised the principles which should guide me. One day, however, and quite suddenly, I put to myself the question: "What are you afraid of?" The reply was, of course, "Heart failure." At once there came the next question: "Do these signs indicate heart failure, or do they foreshadow its occurrence?" This brought home to me my lack of knowledge.

I realised at least, clearly, the difference between the mere recognition of a sign—diagnosis—and its interpretation. I saw that prognosis hitherto had been accomplished by a process akin to jumping over an obstacle. One found a sign and called it a disease, instead of attempting to elucidate the mechanism of its appearance, or labouring to watch the responses to the calls of life of the man or woman showing it. That kind of "prognosis" was a double guess. One guessed that a murmur meant heart disease, and then one guessed again that heart disease meant an early death. Thus there was forced on me the need to watch and to follow individuals with all forms of cardiac abnormality, year in and year out. To study them in health and in periods of acute illness. To be with them during prolonged bodily exertion. To note, if possible, the very earliest signs of heart failure, and to observe every variation of these signs during the years of their development. To make myself familiar with periods of improvement and with periods of regression. Finally, to be present if patients died and to undertake post-mortem examinations. These labours I made some attempt to carry out. Their results will be detailed later.

GIFT FOR X RAY RESEARCH.—The board of management of the Royal Infirmary, Manchester, have accepted a gift of £1000 from an anonymous donor in aid of research work in connexion with "Intensive X Ray Therapy." The donor expresses the desire that a portion of this money should be expended in paying the expenses of a research scholar who is to study the methods adopted in various clinical centres—e.g., Erlangen, for the utilisation of intensive X ray therapy in relation to the treatment of cancer. The intention of the donor is to stimulate inquiry into a recently suggested means of dealing with malignant disease. Dr. Anderson, who was trained at the Liverpool Royal Infirmary under Dr. Thurstan Holland, has been appointed res scholar, and he will shortly proceed to Erlangen. board of management have also made arrangem have the necessary apparatus fitted up in their department.

A Clinical Lecture
ON THE
SURGERY OF THE PITUITARY GLAND.

Delivered at the London Hospital on March 19th, 1921.

BY A. J. WALTON, M.S., F.R.C.S., M.B., B.Sc.,
SURGEON TO THE LONDON HOSPITAL.

IT is one of the most distressing and disheartening things in life to realise how largely our appearances, our actions, our morals, and our very destinies are dependent upon our internal secretions over which we have no control. Just as gross changes in certain glands cause marked symptoms, so also is it probable that variations in character are due to smaller changes. Are we then to condemn a person as dull and uninteresting because his thyroid secretion is diminished, while we praise the greater activity and alertness that accompanies a slightly increased secretion? Are we to condemn as grossly immoral one with well-developed sexual glands and accept as an example of moral rectitude one who has suffered from parotitis in adolescence? Is a patient with a lowered pituitary output to be regarded as mentally weak and foolish, while one with an increased secretion is to be praised for his bright intelligence and keen mentality? Rather do we hope that by careful study of the effects of the internal secretions we may be enabled in the future to alter the characters of many and restore to them the power of enjoying those two things in life that are most worth having—namely, physical fitness and sunshine in the open country. Of the more gross changes our knowledge has already advanced considerably, and I propose to discuss to-day the marked changes that the pituitary gland, which is little, if any, larger than a bean, may cause in the whole body when it is the seat of disease. In order to group the symptoms in a manner easy of understanding, I must briefly consider the development and functions of the normal gland.

DEVELOPMENT OF THE NORMAL PITUITARY GLAND.

From the roof of the stomadeum immediately adjacent to the oral plate there grows upwards a small pouch known as Rathke's pouch. From the floor of the fore-brain there is a corresponding downgrowth known as the infundibulum. These two processes come into contact and together form the pituitary body. The cells of the anterior portion undergo considerable proliferation. At first they form a somewhat triangular sac known as the pituitary sac. The cavity later becomes filled up and the proliferating cells form glandular spaces containing a small amount of colloid material. This portion remains distinct in adult life and is known as the anterior lobe. The stalk corresponding to Rathke's pouch passes, in the fœtus, immediately in front of the notochord and between the trabeculæ cranii, thus later, when these structures fuse to form the basi-sphenoid, all communication is shut off from the pharynx. It is interesting, however, to note that certain squamous-celled tumours may arise in or about the pituitary and that Duffey states that they probably originate in the remnants of Rathke's pouch, which may persist in the body of the sphenoid bone or beneath the capsule of the upper surface of the anterior lobe. The anterior lobe forms about two-thirds of the total pituitary gland. The infundibulum grows downwards and enlarges at the extremity to form the posterior lobe. Although it loses its lumen the infundibulum persists and forms the stalk of the pituitary which connects the gland th the floor of the third ventricle. Between the portions, formed in part from the anterior and art from the posterior, is the pars intermedia, in which persists the cleft corresponding to the pituitary sac.

The fully developed pituitary body is a rounded structure, somewhat flattened from above downwards, which fills the pituitary fossa of the sphenoid bone. It is about half an inch in its widest diameter and is entirely surrounded by dura mater. The pituitary fossa is roofed in except for a small opening in the centre, through which passes the infundibulum. The relationships of the gland are of extreme importance surgically. Below it rests upon the portion of dura mater lying upon the basi-sphenoid. The latter is deeply hollowed out anteriorly by the sphenoidal sinus, from which cavity the pituitary gland is only separated by a thin layer of bone. The antero-inferior wall of the sphenoidal sinus is formed laterally by the cornua sphenoidalia and medially by the ethmoidal spine, to which is attached the vomer. Hence, if an instrument be driven up the sphenoidal sinus through the nose, it will pass up through the basi-sphenoid into the pituitary fossa. Anteriorly lies the olivary eminence, on which is placed the optic chiasma, so that this structure and the commencement of the two optic nerves lie immediately in front of and above the pituitary gland. Laterally the cavity is bounded by the reflection of the dura mater which forms the cavernous sinus and which contains the internal carotid artery and the third, fourth, fifth, and sixth nerves. Anteriorly the internal carotid turns upwards on the outer side of the optic nerve. The anterior cerebral and communicating arteries together form a bridge uniting the two carotids across the upper surface of the optic nerves, which may be compressed by the arteries when the pituitary enlarges. Immediately behind the internal carotid the anterior portion of the optic tract lies on the outer border of the pituitary fossa. Posteriorly is the depression at the apex of the petrous bone, forming the cavum Meckelii, in which lies the Gasserian ganglion. Posteriorly, the dorsum sellæ, with the posterior clinoid processes, sharply limits the pituitary fossa. Within the fossa and surrounding the gland is a small sinus, the circular sinus, formed by anterior and posterior transverse channels which pass from one cavernous sinus to the other. It will thus be seen that the gland is closely surrounded by most important structures and that surgical approach is associated with considerable difficulty.

STRUCTURE AND FUNCTIONS.

The anterior lobe is formed of a glandular epithelial structure, the glands being tubular in nature and the whole portion being extremely vascular. The glands have no ducts and may often contain a colloid-like material very similar to that of the thyroid gland. The pars intermedia, which surrounds the cleft, is also epithelial in nature, but less coarsely granular. The epithelial cells are arranged in vesicles which also contain colloid material. It is said, however, that the colloid of the pituitary gland never contains iodine. The posterior lobe is formed of a vascular connective tissue which has lost its original glial structure and more closely resembles true connective tissue.

There is still a certain amount of doubt as to the actual functions served by the different portions, for both experimentally and clinically it is difficult to obtain a lesion which is limited wholly to one or other lobe. There even seems to be some doubt as to the effect of total extirpation. Cushing found that complete removal was followed by the death of the animal, but Sir Victor Horsley obtained opposite results. The posterior lobe is usually grouped with the pars intermedia and it is probable that the greater part of its function is due to this latter portion, for it is difficult to see how a structure formed mainly of connective tissue, like the true posterior lobe, will have any definite function. Evidence at present obtainable indicates that the functions are as follows:

Anterior Lobe.—The secretion of this portion would appear to control calcium metabolism and the growth of the skeleton, including the bony, cartilaginous, and connective-tissue structures. Possibly it may control the deposit of fat and the growth of the sexual glands.

Posterior Lobe.—The secretion of this portion, which includes the pars intermedia, has very definite effects. Extracts which are now so largely used in clinical medicine are dependent upon the secretion of this portion. The constituents are several in number and may be grouped as follows :—

(*a*) A pressor body. Injection of the extract is often followed by a very marked rise in the blood pressure, and for this reason pituitary extract is very frequently used to combat surgical shock.

(*b*) A depressor body. There is a constituent which, after the pressor effect has died away, leads to a decrease in the blood pressure. The activity and time of onset appear to be variable, so that occasionally, when the pituitary extract is given to a normal person, or to a patient suffering from shock, the depressor effect will be the first to become evident; hence the use of pituitary extract is not wholly without danger.

(*c*) A diuretic body. There is a constituent which appears greatly to increase the secretion of urine, and leads to a very definite polyuria which is associated with dilatation of the renal vessels. In this respect the effect upon the arteries differs from that upon the arteries of the rest of the body.

(*d*) A galactagogue. When pituitary extract is administered to a lactating animal there is marked increase in the flow of milk, but this is apparently only of short duration, so that the total flow over a prolonged period does not seem to be definitely increased.

(*e*) One of the most constant effects appears to be powerful contraction of unstriped muscle. This is especially noticeable in the intestine and uterus, so that the extract is largely used in the treatment of various forms of intestinal paralysis and in some varieties of uterine inertia.

(*f*) There is a body, the presence of which appears to diminish the carbohydrate tolerance. There is some doubt as to whether this body is formed by the anterior or posterior lobes, but it is more probable that it comes from the anterior, for with all conditions of hypopituitarism the tolerance is usually increased, whereas glycosuria may be present with acromegaly. In some cases it would seem that the anterior lobe, and possibly the pars intermedia, may take the place of the thyroid or sexual glands, for there is an increase of the colloid material after a thyroidectomy, during pregnancy, and after castration.

CLINICAL DISTURBANCES.

The symptoms associated with lesions of the pituitary fall naturally into the three following groups :—(1) Disturbance of the internal secretions. (2) Local pressure effects. (3) General pressure effects. It not uncommonly happens that all three of these groups are present in the same case but in others only one or more may be found.

(1) *Disturbances of Internal Secretion.*

Just as there is considerable doubt as to what functions should be apportioned to the different parts of the gland, so there is also some doubt as to which parts of the gland are mainly at fault in different diseases. The following is, however, in the light of our present knowledge, a useful working classification :—

Anterior Lobe.—(*a*) Increase of function: (1) In young patients = gigantism; (2) in adults = acromegaly. (*b*) Decrease of function: (1) In young = lack of growth, ateliosis (Lorain's disease); (2) in adults (?).

Posterior Lobe.—(*a*) Increase of function (?); (*b*) decrease of function: (1) In young = dystrophia adiposa genitalis (Fröhlich's disease); (2) in adults = adiposa dolorosa.

Gigantism.

It is probable that not all giants have a lesion of the pituitary gland, but that there is a close association has been realised since the work of Sternberg, who showed that 20 per cent. of acromegalics are giants and 40 per cent. of giants develop acromegaly. Post-mortem examinations of giants show also that the pituitary gland and the pituitary fossa are very frequently enlarged. Brissaud was the first to point out that acromegaly was probably gigantism of adult life, or that gigantism could be regarded as acromegaly occurring during the period of growth. He also showed that examples of acromegaly and gigantism might be found in the same family. As a general rule the overgrowth is symmetrical, and beyond being of unusual size the patient may show little or no abnormality.

Acromegaly.

This condition, first completely described by Pierre Marie in 1886, appears to be definitely dependent upon an enlargement of the pituitary gland. There is nearly always an overgrowth of the anterior or glandular portion of the gland, but cases are reported in which there has been a hæmorrhage or the formation of a cyst in the anterior lobe. Males and females appear to be almost equally affected and the disease most commonly commences after the age of 30. It has been reported, however, as commencing at a much earlier age, and it is in such cases that there is more likely to be a general overgrowth leading to gigantism. The onset is as a rule slow, but when well established the changes are very characteristic and easily recognisable.

Spine.—The individual bones are thickened and there is a definite kyphosis. The patient may not notice a general increase in the height, but some will state that they have grown several inches since the onset of the symptoms. In three of my cases the height had increased from 1–3 inches.

Thorax.—The thorax is markedly enlarged, widened, and deepened. It projects more in the lower part and there is a wide subcostal angle. The pelvis is enlarged in all directions and the bones are generally thickened. This is especially noticed in the iliac bones and at the points of muscular attachment.

Head and Face.—It is in this area that very characteristic changes are seen. The cranium is but little altered, but the face as a whole shows general hypertrophy, especially in the vertical direction. The forehead appears low and narrow, but the orbits are much enlarged and thickened and an X-ray will show that to a certain extent this is due to an increase in the size of the frontal sinuses. Owing to the size of the orbital margins the temporal areas appear to be depressed. The upper jaw shows a slight overgrowth, but the lower jaw shows a very marked hypertrophy. The method of the overgrowth is unusual. It is not due, as would be expected, to a simple deposit of bone beneath the periosteum, because the individual teeth become widely separated from one another, and hence there must be an increase of the bone throughout. In the late stages the teeth are so much separated that they form an arch greater than that of the upper teeth. At the same time they may be everted by the pressure of the hypertrophied tongue. The jaw is enlarged from above downwards; the great length of the face is largely due to the hypertrophy in this area. An X-ray will show overgrowth of the bone in the orbital regions and some thickening of the tables of the skull. The pituitary fossa is generally enlarged, and there may be atrophy or erosion of the clinoid processes. The changes are not limited to the bone: the eyelids are thickened and hypertrophied and the nose is considerably enlarged, being lengthened and widened from side to side. The tissue over the cheeks is thickened and prominent. The lips are greatly swollen and thickened, being often negroid in type. The tongue is hypertrophied, so that it may project beyond the teeth and may interfere with speech. The ears are also thickened and enlarged.

Hands and Feet.—The changes in the hands and feet are even more characteristic than those in the head and face. They are much increased in size, the enlargement being due to an increase in the width rather than in the length. This is especially noticeable in the feet; patients will often state that since the onset of the disease they have had to take two sizes larger in boots, and that even then a labouring man's boots have to be used in order to gain the increase in width. The thickening in the hands is seen to consist of all the tissues, bones, muscles, connective tissue and skin, but the fingers are more or less cylindrical and much wider than normal. The nails do not share in the hypertrophy, so that they seem to be relatively small. The thenar and hypothenar eminences are increased in size, but the subcutaneous tissue does not pit and the thickening is therefore not due to œdema. The feet are affected in a similar way. There is a great increase in the width, especially at the base of the toes, and the heels may appear massive. The toes are all enlarged and more cylindrical than normal, especially the first toe. The X rays may show in the early stages little or no change in the bone, the hypertrophy being due to an increase of the soft tissues, but in more advanced cases there is always a definite deposit of new bone, especially under the periosteum of the proximal phalanges. Even when the heels appear to be very massive the X ray will often demonstrate that there is no change in the astragalus. As a rule the hypertrophy does not extend beyond the wrist and ankles, but not uncommonly there is a marked muscular hypertrophy of the arms and legs. In the later stages of the disease the muscles may atrophy. Occasionally an X ray will show that the distal extremity of the limb bones have a new deposit of bone beneath the periosteum, but as a rule they are unaffected.

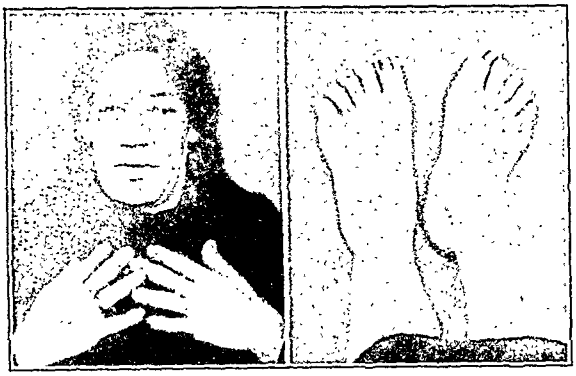

FIG. 1.—Typical case of acromegaly, showing changes in face, hands, and feet.

Sexual Glands.—These also show very constant changes. In women the breasts become smaller than normal, and amenorrhœa is one of the earliest symptoms. The external genitalia are hypertrophied, both in the male and female, but there is always a marked decrease in sexual desire.

On the vascular side the heart is often hypertrophied, the arteries are thick, and the veins varicose. The blood pressure is generally high, but often shows a marked variation. The thyroid may be small and the larynx hypertrophied, so that in women the thyroid cartilage may be as prominent as in men and with this the voice becomes deeper and stronger. The skin shows profuse sweating and pigmentation, the hair becomes very coarse and wiry, and in women its distribution becomes more of the male type. The intelligence is as a rule good, and in two of my cases the women were of unusual intelligence —were, in fact, the guiding spirits in their homes. Later there may be a general depression of the mental functions, with drowsiness, but this probably only occurs when the general symptoms of pressure are becoming more in evidence. There is often polyuria, and not uncommonly a marked glycosuria which can usually be controlled by diet. In the early stages especially, the patients will often complain of severe pain in the limbs and joints, of headache, and pain in the eyes. It will be seen therefore that in females this disease tends rather to produce the male characteristics. There is a general increase in the skeleton with muscular hypertrophy, an overgrowth the hands and feet with hypertrophy of the alanges, an alteration in the larynx with a deepening of the voice, an alteration in the distribution of the hair with atrophy of the breasts, and the development of a more masculine intelligence.

The following is a typical example of the disease.

CASE 1. *Pituitary Tumour with Acromegaly.*—J. S., a married woman, aged 42, was quite well until seven years ago, when she commenced to have pain and stiffness in the neck, so severe that she could not move her head. This has continued ever since. Shortly after she noticed her hair getting coarser and more curly. Four years ago she noticed hands and feet getting bigger, so that she had to wear boots two sizes larger; also noticed a marked but gradual change in her features. For six months her tongue has been getting bigger, and now interferes with speech. Sight has been altering for two years; she noticed that she was getting blind at the sides and now feels as though she were looking through a tube. For seven months she had severe thirst, and glycosuria was then discovered.

On examination there are characteristic changes in the face. Eyelids thickened and enlarged, orbital ridges massive and prominent; hair dark, coarse, and curly; tongue large; teeth in lower jaw are widely separated; the arch they form lies outside that of the upper teeth. Mouth large, lips thickened; lower jaw massive and prominent. Hands and feet much enlarged, chiefly from side to side; fingers thickened and cylindrical. Since the age of 21 patient has grown 2 inches. Spine is slightly kyphotic; thorax wide and massive, iliac bones enlarged. Patient is extremely intelligent, and has always been engaged in intellectual work; thinks herself that her memory and reasoning powers have been more active in the last few years. Vision very poor; she cannot read with either eye. Marked diminution in fields of vision, more so for white than for movement. Discs show distinct optic atrophy. No circulatory changes. Catamenia ceased at 39. Has had two children, 20 and 17 years ago; four miscarriages. She has never had any sexual desire. She is passing 80–90 ounces of urine a day, which contains 10 per cent. of sugar. An X ray examination shows a great increase in the width of the pituitary fossa and marked enlargement of the frontal sinuses. There is no new bone beneath the periosteum of the phalanges.

She was transferred to the care of Dr. A. W. M. Ellis, who was able with diet to eliminate the sugar from the urine, and in two weeks had raised the sugar tolerance to 100 grammes per diem.

Operation and Result.—After the lecture this patient was operated upon. A large osteo-plastic flap was turned outwards from the left frontal region. The dura was then raised as far as possible from the orbital plate and opened anteriorly. The brain was carefully elevated, and an extremely good view of the left optic nerve and the pituitary gland was obtained. The gland was enlarged and formed a swelling in front of the chiasma. Its capsule was opened and the whole of the gland removed from the dural covering. There was little or no bleeding. The brain was then replaced and the osteo-plastic flap returned.

She made an uninterrupted recovery from the operation and three weeks later was free from the severe pain. The eyesight was still poor; the vision of the left eye, much worse after the operation, has gradually improved, and she can now see nearly as well as before the operation. There has been no return of the sugar in the urine, but she is still on a modified diet.

The pathological report of the gland states that there was a solid spheroidal-celled carcinoma of the anterior lobe of the pituitary, with a greatly compressed fibrotic remnant of the anterior lobe.

Ateliosis or Lorain's Disease.

This may be regarded as the exact reverse of gigantism. The patient is small and has never grown, but the proportions of the different parts of the skeleton remain more or less normal, so that the condition is easily distinguished from achondroplasia. With the lack of growth there is a failure of the secondary sexual characteristics to develop, so that these patients appear to be much younger than they really are, and at the age of 35 or 40 may appear to be only 14 years of age. The bones are small and relatively fragile, and the muscular attachments poorly developed. The junctions of the epiphysis are greatly delayed but the formation of the bones is regular, so that there is no enlargement of the epiphyseal ends as may be seen with achondroplasia and some forms of thyroid insufficiency. The skull is small with thin bones and an X ray may show very definite changes in the pituitary fossa, which will vary with the nature of the lesion. If, as is not uncommon, there is a simple cyst, the fossa may be much dilated and the clinoid process may be absorbed. The lower jaw is badly developed and there is a poor eruption of the teeth. The muscles are ill-developed and are more of the type found at the age of puberty. The skin is soft, delicate, and white, and resembles that of a young female. The body and face remain hairless and the voice is thin, high, and piping, so that the patient, if a male, retains many of the female characteristics. The sexual glands are never developed and the intelligence is always considerably below the normal. The appetite is poor, and there is often an alteration in the secretion of urine; the latter may be increased or diminished. There is no glycosuria, and in some cases the carbohydrate tolerance appears if anything to be above the normal. Later there will be a diminution in the fields of vision owing to local pressure, or the presence of headache from the increased intracranial pressure.

There is, as far as is known at present, no definite disease due to atrophy of the anterior lobe in the adult. It would, however, be of interest to investigate a series of cases of "fragilitas ossium" from this point of view, for the changes they present are those that would be expected with a loss of function of the anterior lobe. There is a similar lack of knowledge of any symptoms associated with an increase of function of the posterior lobe, but I have often been struck by the fact that an unusual intelligence—and by intelligence is meant, not the flabby, insipid condition which to-day is spoken of as an artistic temperament, a thing which is neither an art, nor a science, nor an intelligence, but merely a conceit—is frequently associated with marked physical activity and a high blood pressure, and if minor degrees of hypertrophy of the anterior lobe are, as one is led to believe, associated with a keen intelligence, it is probable that the other factors are dependent upon hypertrophy of the posterior lobe. It will be interesting to note whether, in the future, cases of arterio-sclerosis and chronic nephritis occurring in the young will be found associated with hypertrophy of the posterior lobe.

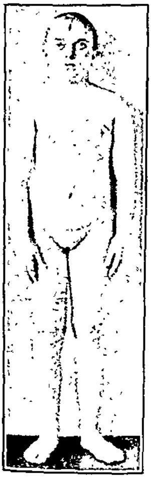

FIG. 2.—Patient, aged 14. Fröhlich's syndrome.

Dystrophia Adiposo-Genitalis (Fröhlich's Disease).

In this variety of disease the characteristic changes consist in a marked overgrowth of the subcutaneous fat. The deposit is more or less general, but has a tendency to be placed so as to exaggerate the female outline of figure, so that in the male there is a relatively greater thickening of the buttocks and thighs, and a subcutaneous deposit in the region of the breasts. At the same time the blood pressure is low, and there is a good or increased tolerance to carbohydrates. There are other changes which are possibly due to an associated diminution of the anterior lobe secretion. The patient, although generally of the normal height, shows a relatively poor development and the epiphyses are often late in joining. The skin is soft and there is no growth of axillary hair, the voice is high-pitched and squeaky, and the thyroid small. The genitalia remain small and undeveloped, and not uncommonly the intelligence is considerably below normal. The X ray often shows very marked enlargement of the sella turcica, for at operation or post-mortem the lesion is not infrequently found to be either a cyst or a tumour which has led to destruction of the pituitary gland.

CASE 2. *Pituitary Cyst with Decrease of Posterior Lobe Function.*—I. J., aged 14, was admitted to the London Hospital on June 11th, 1915. For two years she had had gradual onset of frontal headaches, chiefly noticed in the early mornings, and steadily increasing in severity. One and a half years ago there was a seizure during the night; she woke up and felt queer, and her mother states that she was stiff and unconscious and that she talked and rolled her eyes. For six months she had had occasional curious attacks in which the body shook all over so that she had to sit down. The attacks only lasted for one minute. For one and a half years the eyesight had been failing. At first she did not notice steps when walking and fell over them. Could not see people coming from the side, and was startled when she found them close to her. For seven weeks unable to read print; for six weeks occasional diplopia, and friends have noticed that she squinted; for the last ten days similar fits to the first evening. All occurred at night, and she vomited during and after the fits.

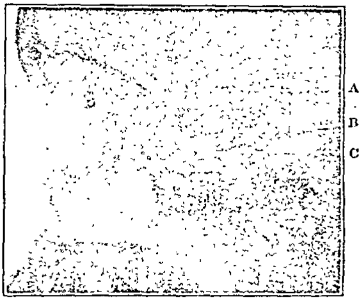

FIG. 3.—Radiogram of part of skull of girl shown in Fig. 3. A, ill-defined shadow above pituitary fossa; B, fossa much enlarged; C, posterior clinoid processes absent.

On examination noticed to be extremely fat; distribution of fat chiefly in trunk and thighs; the face was rounded and infantile. She had never menstruated; there was no pubic hair. Vision much affected; on right side could only distinguish light and darkness, on left side marked contraction of temporal field; both discs showed optic neuritis, which on the right side was passing on to atrophy. Slight incoördination of the rapid movements of right hand, otherwise no changes in the vascular system.

An X-ray examination of the skull showed a marked enlargement of the pituitary fossa, immediately above which was a blurred shadow.

On June 15th a large frontal osteoplastic flap was made on the right side and turned outwards. The dura was opened and the right frontal lobe carefully elevated until the right optic nerve and chiasma were exposed. Beneath the chiasma a large swelling was seen which, when punctured, allowed the escape of 1–5 drachms of thick fluid, which was collected into a tube and found to contain large quantities of cholesterin. A small drainage-tube was inserted and the flap replaced.

The patient made an uninterrupted recovery from the operation, and six weeks later was transferred to the medical side. She made, however, no improvement in her sight, and eight months later a letter was received to say that she remained blind, and had continued to have frequent attacks of spasm until her death at the time of the letter.

It is probable that the condition which Fearnsides has described as the "pudding-face type" is a milder degree of this same disease. There may be a slight general increase of the subcutaneous fat, the face is fat and rounded with red prominent cheeks, and the voice high and piping. The thyroid is often small and amenorrhœa is generally present. As in the

Fröhlich's type there are frequently alterations in the visual fields which may, if left, progress to complete blindness.

Adiposa Dolorosa (Dercum's Disease).

There is a considerable amount of evidence that this disease bears the same relationship to Fröhlich's disease as acromegaly does to gigantism, and that it is a change due to a diminution of the secretion of the posterior lobe which has occurred after the *normal growth of the body has been completed.* It is characterised by large irregular and generally painful deposits of fat, which may be diffuse in outline or may be more or less localised in the form of lipomata. The distribution of the fat is curious and very characteristic. The face, hands, and feet remain free and the deposit is most marked in the buttocks and thighs, so that at times the portion of the body above the waist is quite normal, while there is a very marked overgrowth in the portion below. At other times the fat is deposited in the back and shoulders and sometimes in the posterior aspects of the arms. Dercum himself noted a very marked change in the pituitary gland, but it is only right to mention that in many cases the thyroid has also been affected and that good results are claimed to follow the administration of extracts of this gland.

(2) *Local Pressure Symptoms.*

The chief local pressure symptoms are due to interference with the optic tracts or chiasma. The portion most likely to be affected is the inner part of the two tracts and the posterior portion of the chiasma—that is to say, the fibres which are passing to the two nasal halves of the retina. Therefore one of the earliest symptoms is a diminution in the temporal fields of vision, a bitemporal hemianopsia. Riddoch has shown that even in the early stages there is often a marked disassociation in the fields, not only for different colours but for fixed and moving objects. The fields may be considerably *reduced before the patient is aware of any change,* but he will shortly notice that objects disappear as they pass to one side of his visual field. In advanced cases he may state that he appears to be looking through a tube or opera glasses, or that he feels as if he were wearing blinkers. This alteration in the fields of vision may be found with any of the variations of secretion, or it may be present alone. In the latter case *a tumour is present which has not* arisen from the pituitary itself, and has not yet led to sufficient pressure upon the gland to interfere with its secretion. If the condition be allowed to progress there will be added to the heminanopsia firstly a diminution of the vision in the remaining field and later complete blindness.

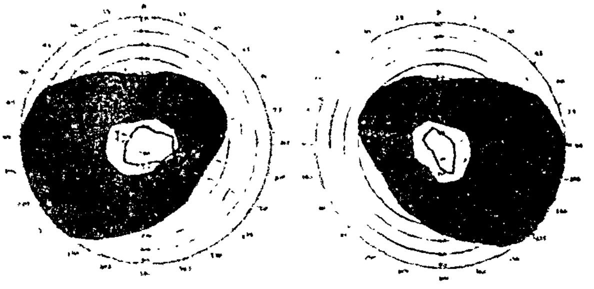

FIG. 4.—Tumour giving localised symptoms only. Field showing marked diminution of vision. Inner field is the area for red; outer field is area for blue.

The other local pressure symptom is much less frequent. It consists of severe attacks of neuralgic pain in one or other side of the face which maps out ther a part or the whole of the fifth nerve. It pears to be due to pressure either upon the serian ganglion or upon the individual branches he fifth nerve.

CASE 3. *Pituitary Tumour with Local Pressure Signs.*—S. B., a woman aged 55, was admitted to the London Hospital on Oct. 23rd, 1915. For 18 months had noticed her eyesight gradually failing; had to give up first fine needlework and later reading. For the same length of time there had been pain in the back of eyes and down left side of face. In October, 1913, examined by an oculist, who discovered bitemporal hemianopsia; in April, 1914, the nasal fields had also become restricted. Never severe headaches, and has not noticed any changes in the body structure. On examination found to be a healthy-looking woman, with a normal spine and skull. Mentally acute; no changes seen in body structure; thyroid gland normal. At this time, Oct. 23rd, 1915, marked contraction of the fields of vision; left eye almost completely blind, and could only just distinguish light and darkness; on right side complete loss of temporal field and considerable contraction of nasal field. An X ray examination showed a marked enlargement of pituitary fossa.

On Oct. 25th, 1915, an operation was performed by the frontal route. A left frontal flap was turned outwards as in the last case and the brain carefully elevated after opening the dura. A good view of the pituitary gland was seen and *it formed a round bluish-red mass with the left optic nerve stretched and flattened over its surface.* Owing to the practically complete blindness on the left side and the appearance of the optic nerve, it was decided that the vision could not be recovered, and the nerve was therefore divided. The tumour was then incised, and found *to be formed of a soft but solid material, which was easily scooped out.* This left a firm wall lying in the dilated sella turcica, from which there was little or no bleeding. Brain replaced and the wound closed.

Patient had a somewhat stormy convalescence, and for five days had aphasia and weakness of the right arm, and to a lesser extent of the right leg. This gradually improved, and six weeks later she was able to walk about the ward, her speech having completely recovered. In the first few days pituitary extract was administered, but this appeared to lead to a marked increase of the mental dullness, and it was therefore omitted. The pathological report states that the tumour was a solid acinar carcinoma of the pituitary.

Since operation patient has progressed favourably. A letter dated April 1st, 1921, states that she has marvellously recovered, and can do her own housework. The left eye is still blind, but there is a considerable improvement in the sight of the right. All pain and headache have ceased.

(3) *General Pressure Symptoms.*

A pituitary tumour, being situated within the calvarium, will sooner or later lead to an increase of the intracranial pressure. The extent of the pressure will vary considerably with the nature of the lesion. A tumour may be present which is essentially a cerebral tumour but which, growing downwards, interferes with the pituitary gland. In this case there will be *marked evidence of intracranial pressure* with slight signs of pressure upon the optic nerves and some evidence of a secondary diminution in the pituitary secretion. On the other hand, a lesion which commences in the pituitary gland will give a very marked interference with its functions, and definite local pressure signs, while it is only in the later stages that the neoplastic mass presses upwards sufficiently to give a marked increase in intracranial pressure. The first symptom is headache, and it is often difficult to determine how much of the pain is due to pressure upon the fifth nerve and how much to general increase of intracranial pressure. The early changes of optic neuritis are also often obscured by primary atrophy due to pressure upon the chiasma. The majority of cases of pituitary lesion which have been *traced to a fatal termination* present at the end definite evidence of an increase in the general intracranial pressure.

TREATMENT.

Most observers have laid stress upon the difficulty of classification of the pathological lesions found. It is now, however, generally recognised that the tumours, excepting only the rare forms of squamous carcinoma, are, as a rule, relatively benign and should be described as adenomata, in spite of the fact that microscopically they often appear to be carcinomatous. They resemble adenomata of the thyroid in so far that they frequently have a function. On the other hand, those conditions in which there is a diminution of the secretion are usually associated with a cyst or some form of tumour, which instead of giving rise to an increase of function causes pressure atrophy of the gland. A true atrophy of the gland seems to be extremely rare, and the X ray photographs, as a rule, show an expansion of the pituitary fossa. Hence, on a priori grounds satisfactory results would be expected to follow operative interference in both types of case. On the one hand it would remove the tissue which was giving an excessive secretion, and on the other it would remove the structure which was causing the pressure atrophy. It must, however, be remembered that most of the conditions associated with an alteration of secretion are very slow in their progress. They may persist for years, and some of them, especially indeed acromegaly, may regress after a prolonged period. The operation is one of very considerable severity, and is bound to be associated with a relatively high mortality. For this reason it is doubtful whether an operation will frequently be advocated simply to relieve the hypo- or hyper-pituitarism. The chief indication will therefore be the presence of local or general pressure symptoms. If the visual fields are rapidly diminishing in size and there is danger of complete blindness an operation should certainly be considered, and the same is true if there is increasing headache or vomiting. The presence of definite early optic neuritis in addition to the commencing atrophy will be sufficient to warrant surgical interference. The presence of marked glycosuria in cases of acromegaly will generally indicate rapid progress of the lesion; but since (as in the case recorded above) it may be temporarily cured by medical measures it is often an indication rather than a counter-indication to operation. A rapid increase in the symptoms due to the changes in the internal secretions may also be regarded as an evidence of rapid progress, and therefore an indication for interference.

So much has been written of late on the different methods of approach that it is unnecessary to consider them again in detail. My own experience has been that an infinitely better approach can be obtained by the cranial route, and that although this operation may be somewhat more severe than the intranasal, it gives a very much better opportunity of removing the whole growth, which, as Cope has shown, tends at an early period to enlarge upwards. The operation therefore which I favour is a modification of the Frazier method. A large frontal flap is made and turned outwards. The lower limb passes around the margin of the eyebrow and the upper lies about three and a half inches above this, parallel to it, and thus well within the area of the hairy scalp. These two incisions are connected by a vertical limb in the middle of the forehead. The flap is made on the side which shows the greater diminution in the visual field, for it may happen that removal of the tumour will necessitate some interference with the optic nerve; hence it will always be wiser to interfere with the eye which is of less value. The incisions are deepened to the bone and trephine openings made in each corner. The four openings are united with a Gigli saw; the bony flap, which is thus about three inches square, is lifted up and turned outwards while still attached to the superficial tissues. The dura is now elevated as far as possible from the orbital roof, and when the limit of this reflection has been reached, an opening is made into it parallel with the orbital ridge. The frontal lobe in the brain is carefully elevated with a broad metal retractor, and the cerebro-spinal fluid gently swabbed away. Great caution must be exercised in elevating the brain lest the retractor cut into it. After a short period of careful sponging a clear view is obtained of the optic nerve and chiasma, and the pituitary gland and any tumour may be removed from the position in which it is most prominent. This is usually in front of and below the chiasma. By performing these steps slowly and carefully I have found that it is quite unnecessary to remove the orbital ridge and plate as advocated by Frazier. The operation is thus shortened and the possibility of resulting deformity is diminished. In only one case have I found it necessary to divide the optic nerve. In the others, although the operation has occasionally been followed by a slight increase in blindness, the latter has always improved. As soon as the tumour has been removed the dura is closed and the bone replaced.

The above operation—which, based upon Frazier's method but differing from it in that the orbital ridge and plate are untouched and that the dura is opened relatively early so as to allow the elevation of the brain—has now been performed in five cases. One was a case of acromegaly, one presented Fröhlich's syndrome, two had local pressure symptoms alone, and one had local and general pressure symptoms. In every one of them an almost perfect view was obtained of the pituitary gland. The optic chiasma and the optic nerve and tract on that side were clearly visible. The extent of the tumour could be determined, a point which is especially valuable when it has grown upwards out of the fossa. In no case was it difficult in removing the tumour to reach to the bottom of the sella turcica, and in this respect it appears to give as good an approach as can be possibly obtained by the intranasal route. In the one case where the optic nerve was destroyed the division of this structure greatly increased the view and allowed of easy removal of the tumour. If performed slowly and carefully the amount of shock is very much less than would be expected and in several cases it was hardly noticeable. Of the five cases two died from the immediate effects of the operation. Of the remaining three the one with Fröhlich's syndrome died eight months later with symptoms of the disease, probably from a re-filling of the cystic cavity. It is of interest to note that in the patient who has survived for five years the pathological report stated that the condition appeared to be carcinomatous.

A NEW GENERAL ANÆSTHETIC:

ITS THEORY AND PRACTICE.*

BY R. L. MACKENZIE WALLIS, M.A., M.D.
CANTAB.,
CHEMICAL PATHOLOGIST, ST. BARTHOLOMEW'S HOSPITAL;
LECTURER IN CHEMICAL PATHOLOGY IN THE MEDICAL
SCHOOL, ST. BARTHOLOMEW'S HOSPITAL;

TO THE MEDICAL SCHOOL OF ST. BARTHOLOMEW'S HOSPITAL;
ANÆSTHETIST TO THE QUEEN'S HOSPITAL FOR CHILDREN,
BETHNAL GREEN.

PART I.—BY R. L. MACKENZIE WALLIS.

THE observations recorded in this paper have been obtained by us with the use of a new anæsthetic compound. The theory and chemical details have been worked out by myself, and the application of this compound as an anæsthetic by Dr. Langton Hewer. The details of manufacture will be described in the first part of the paper, and the results obtained upon a large number of patients in the second part. The discovery of a compound possessing powerful anæsthetic properties, which has no relation chemically to either chloroform or ether, is the result of many years of work upon the subject.

Such chemical compounds as ether and chloroform were known for many years before they were applied as agents for producing general anæsthesia. The history of anæsthesia and anæsthetics is of comparatively recent origin, and it is not surprising therefore to find many gaps in our knowledge. A vast amount of work is necessary before this difficult and complex subject is elucidated; and we are at present merely working on the borderland.

---

* A paper read before the Section of Anæsthetics, Royal Society of Medicine, April 1st, 1921.

The Use of Ether as a Vehicle.

For many years I have been engaged upon the problem of the purification of ether; and during my service in India had unusual opportunities of pursuing this subject. The knowledge so gained has since been extended. With pure ethyl alcohol and pure sulphuric acid it is possible, under certain conditions, to prepare ether free from alcohol and water. This ether, when fractionally distilled, yields about 50 per cent. of distillate at a temperature of 34·5° C., and practically the whole of the remainder comes over between 34·7° C. and 34·8° C. There is only a very small residue left. Pure ether obtained in this way, when freshly prepared, can be given in large quantities to animals without producing anæsthesia—in fact, the preparation exerts an intoxicating action; moreover, even were this pure product of use for producing anæsthesia, its cost would be prohibitive. Having established this point it became obvious that the anæsthetic properties were wholly due to one or other of the compounds contained in ordinary anæsthetic ether. In view of its volatility, and moderate toxicity, pure ether was evidently the best vehicle that could be used for the preparation of an anæsthetic. Attempts were therefore made to purify ordinary ether for this purpose. The problem was somewhat complicated by the fact that during the war ethyl alcohol became very costly, and available only in limited quantities. The only other source was "industrial spirit," consisting of a mixture of ethyl and methyl alcohols; and this became the sole source for the preparation of anæsthetic ethers. It appears now to have superseded ether made from rectified spirit; and from the point of view of cost alone its use is to be recommended.

Impurities Contained in Ether.

Many samples of ether prepared in this way were found to contain not only the three ethers—viz., dimethyl, diethyl, and methyl-ethyl ethers—but, in addition, abundant impurities. There is no doubt that whereas pure ethyl ether undergoes oxidation on standing, it does not do so as readily as the methylated ether. There are, therefore, much larger amounts of impurities in the latter ethers. The chief preformed impurities are alcohol, water, acetone, and mercaptans and thio-ethers. Those formed by oxidation of the ether comprise aldehydes, peroxides, and acids. Carefully prepared samples of ether naturally contain very small quantities of these impurities, but the purer the sample, the more of it is required to produce anæsthesia. It follows, therefore, that if larger quantities are used, the actual amount of impurities administered may be considerable.

Removal of Mercaptans.

The methods usually adopted for purifying ether were systematically investigated, and it was found that most of the impurities were thereby removed. The removal of the chief impurity—viz., mercaptans—proved to be a much more difficult problem. A procedure was ultimately found whereby the mercaptans are completely removed from the ether, and this appears to be the most important part of the process. By distilling ether with very finely divided permanganate it was found that oxidation of the impurities occurred, and if a special reflux condenser was adopted all the mercaptans were retained in the residue. Quantities of ether were treated in this way, and the residues collected. The residue was found to possess an evil odour, and to be extremely poisonous. A mere whiff from the bottle is sufficient to produce a feeling of nausea, and considerable irritation of the nasopharynx. Inhaling even small quantities of the residue rapidly induces a severe headache. The permanganate in a finely divided form adsorbs this most potent impurity, and thus removes it from the ether. This is evident if one separates the permanganate after distillation, and subjects it to a stream of dry air. The permanganate gives off the mercaptans completely, and may be used over and over again. Iodine also destroys mercaptans, but its use in place of permanganate is inadvisable for many reasons, chief among them being the difficulty of removing traces of iodine which distil over with the ether.

A Pure Ether Finally Obtained.

The ether so treated is quite free from aldehydes and mercaptans, and contains only traces of alcohol, water, and peroxides. To remove these remaining impurities the distilled product is treated with anhydrous copper sulphate. At first I redistilled over the copper sulphate, but ultimately this was found to be unnecessary, mere shaking and standing being quite sufficient. By this process a remarkably pure ether is obtained, which keeps well, and only slowly undergoes oxidation. The ether prepared in this way has been used as a vehicle for the anæsthetic compound.

Importance of Recognising Certain Impurities in Anæsthetic Ether.

The occurrence of impurities in ether can be best studied in such a climate as India, where ether, especially methylated ether, rapidly undergoes change. One batch of ether I tested was so impure that the evaporation of a small quantity in the laboratory was sufficient to make the place untenable. Salivation, lacrymation, and a severe headache followed the inhalation of fumes derived from evaporation of a few cubic centimetres of the sample labelled "anæsthetic ether." The peculiar odour attracted my attention, and inquiry revealed the presence of quantities of methyl and ethyl mercaptan in these samples. These compounds, in my opinion, were responsible for the unpleasant effects produced. My colleague, Dr. Langton Hewer, came up one day in April, 1920, with the residue of a bottle of anæsthetic ether which he had used on two patients, both of whom had stopped breathing soon after administration of the ether. I at once detected the same odour, and found that the chief impurity in this ether was the mercaptans. Many samples of ether were therefore tested, and the great bulk of them showed this impurity in varying quantities. It appeared obvious that such compounds with their irritating properties were of no use, and that it was highly desirable that they should be removed. Their removal was found to be effected by the use of permanganate as described above. The other impurities were easily removed, but in so doing I removed some compound or compounds which were of importance, since the highly purified product was no longer capable of producing anæsthesia.

At this juncture my attention was called to the production of an ether in America by Dr. J. H. Cotton, who used carbon dioxide and ethylene dissolved in ether. In experimenting with the use of carbon dioxide and ethylene I was struck by the differences in the amount of these gases absorbed by various samples of ether. Absolutely pure ether apparently takes up very little carbon dioxide and ethylene. The ether prepared by the process described above was found to behave quite differently. Using good samples of anæsthetic ether it was found that whereas before distillation practically no gases were absorbed, after distillation with permanganate and copper sulphate comparatively large quantities could be absorbed by the ether. This preparation was found to be extremely potent as an anæsthetic, as I had good reason to realise from personal experience.

Properties of the Pure Ether.

The pure ether was practically non-irritating, but possessed a pleasant odour and a rather stimulating effect. It was free from aldehydes, peroxides, acids, and water. When treated with carbon dioxide and ethylene its sweet pleasant odour was intensified. This preparation was made, and after being tried upon animals with success by my colleague, Dr. Philip Hamill, it was resolved to try it on human beings. Dr. Langton Hewer, whose keenness and courage I much appreciate, set to work and gave this anæsthetic to about 100 cases. All the material was prepared by myself in the laboratory with the standard process which had been evolved. I leave it to him to describe the results he has obtained. In the meantime the peculiar properties of this anæsthetic were further investigated. Ethylene prepared from ethyl alcohol and sulphuric acid possesses a very pleasant odour, but very little anæsthetic power. When prepared by means of phosphoric acid this pleasant odour is not so obvious, and the ethylene so prepared has a much reduced action when dissolved in ether. It was obvious that the carbon dioxide played little, if any, part in producing anæsthesia, since ether and carbon dioxide alone were found to be without action. It, however, exerts a stabilising effect, as pure ether, treated with dry carbon dioxide, does not undergo oxidation so readily as pure ether alone.

The Ketones as Anæsthetic Agents.

The outcome of these investigations was to show that certain ketones in the ether were largely responsible for the anæsthetic properties of the ether. Good anæsthetic ethers, free from aldehydes, mercaptans, &c., when treated with finely divided permanganate, yielded a pleasant-smelling residue instead of the evil-smelling residues previously obtained. This residue proved to contain ketones, and these compounds appeared to be the essential element in the production of a good and safe anæsthetic. The mixture of ketones proved to be very potent, and it was necessary to use a volatile solvent. In view of the readiness with which ordinary ether can be purified, this compound was selected as the solvent. Into this pure ether the mixed ketones were placed in varying proportions, and the mixtures so obtained were found to be capable of producing anæsthesia. The anæsthetic action was enhanced if the mixed ketones were first treated with carbon dioxide and ethylene. The ketones used comprise those in the middle of the series, and a loose chemical combination between these substances and the carbon dioxide and ethylene apparently results. In attempting to purify ether, therefore, the discovery was made of the importance of certain impurities—viz., the ketones. This opens up a wide field for future investigation, and much further work is necessary before it can be said that the ideal general anæsthetic has been obtained. All the material necessary for the application of this mixture as an anæsthetic was made in the laboratory, and supplied as required to my colleague, Dr. Langton Hewer. As soon as its value as an anæsthetic was established, and requests made for trial purposes by other anæsthetists, it became necessary to place its manufacture in other hands. The preparation of this anæsthetic, according to the method described above, has been undertaken by Messrs. Savory and Moore, who have now placed it on the market under the name of "Ethanesal."

PART II.—BY C. LANGTON HEWER.

I will first of all describe the observed effects of this anæsthetic, ethanesal, on the various metabolic processes.

1. *Respiratory System.*—The respiration-rate rises slightly during the induction but not to such a great extent as with ether. When fully anæsthetised the patient's respirations are usually quieter than with ether, and more closely resemble those of chloroform anæsthesia. The irritation of the mucous membrane of the respiratory passages is much less than with ether, as is shown by the ability suddenly to increase the strength of the vapour without causing coughing or spasm. The salivation is considerably less than with ether, and if atropine has been previously given, it is usually almost non-existent.

In 200 cases I have only had one with post-operative bronchitis, and this occurred in a myxœdematous girl who had to be conveyed for about 100 yards in the open air from the theatre. The temperature outside was below freezing-point at the time. On the other hand, the anæsthetic has been given to 10 patients with well-marked bronchitis, as shown by dyspnœa, cough, sputum, and sibili in the chest. None of these cases showed any aggravation of the symptoms, and two of the number appeared to be actually better after operation.

2. *Cardio-Vascular System.*—The effects of this anæsthetic on the blood pressure and pulse-rate are shown on the accompanying graphs. These were obtained by calculating the averages of a number of cases whose operations were of approximately the same severity. The actual pressures could obviously not be given, as the normal for each individual varies between wide limits. Consequently the normal has been taken as that of the patient before operation. This is probably slightly too high, owing to the psychical effect of anticipation, but the error may be neglected as it occurs in all the curves.

As the length of time of the operations varied, there is an interval of more than five minutes between the 25 minutes' time and the end of the operation. Otherwise I think the graphs explain themselves. It will be seen that as regards systolic blood pressure the anæsthetic occupies a position between chloroform and ether. It is specially noticeable that the drop in pressure at the end of the operation, and before the patient is conscious, is less than with ether.

I think that the fairest comparison between the three anæsthetics is afforded by the pulse pressure curves—that is, the difference between the systolic and diastolic pressures. It now appears to be agreed by most authorities that this figure affords a fairly reliable guide as to the condition of the patient, and it will be seen that although it does not rise so high as with ether, yet it is the highest of the three at the end of operation, and afterwards when the patient is conscious.

As regards the action of the anæsthetic on the diseased heart, I have given it to several cases of mitral regurgitation, congenital pulmonary stenosis, and to one case of advanced mitral stenosis with auricular fibrillation, with no ill-effects. I have described this latter case in greater detail below. The anæsthetic has also been given to patients suffering from marked anæmia, from hæmorrhage or other causes. The lowest red blood count was in a man with lymphadenoma, who had 2,100,000 red cells.

3. *Cerebral Processes.*—The three stages of anæsthesia, as described with ether, are observed with this anæsthetic, but can be made to follow one another with greater rapidity owing to the possibility of employing stronger vapour. The excitement stage is usually not so marked as with ether, and if given with gas and oxygen may be entirely absent. It is sometimes possible to procure perfect analgesia without anæsthesia, and if a long extra-abdominal operation is being performed, such as an extensive tendon transplantation, the patient can usually be allowed to become exceedingly light, and may even be blinking his eyes, but will remain quite motionless, breathing quietly, and not feeling pain.

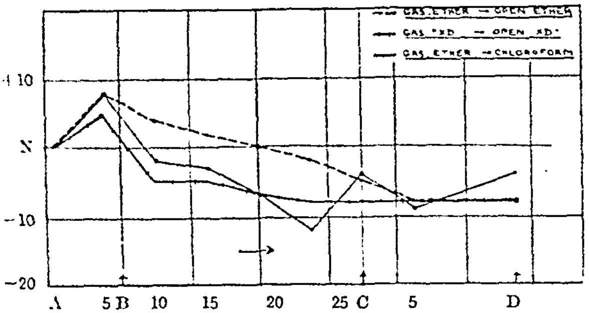
4. *Sugar Metabolism.*—No case of post-anæsthetic acidosis has yet been observed with this anæsthetic. Three patients with well-established diabetes mellitus have been anæsthetised and no ill-effects were noticed. Unfortunately the sugar tolerance of these patients was not accurately estimated beforehand, but there was no appreciable diminution observed afterwards. One child who was passing large quantities of acetone in the urine was given this anæsthetic for half an hour, with no ill-effects.

5. *Effect of the Anæsthetic on Patients with Various Toxæmias.*—Patients acutely ill with various conditions have been anæsthetised. These include neglected perforated gastric and duodenal ulcers, neglected intussusception, toxæmias of pregnancy, &c. Although two of these patients subsequently died of peritonitis, no ill-effects from the anæsthetic were observed; on the other hand, the condition of the patients nearly always improved temporarily when under the anæsthetic.

6. *After-effects:* (*a*) *Vomiting.*—48 per cent. of the patients had no vomiting whatever. 42·6 per cent. retched or vomited once before coming round, but did not remember it, and had no vomiting afterwards. 7·3 per cent. vomited up to one hour after coming round. 2·0 per cent. vomited for over one hour after coming round. No case has had prolonged vomiting extending over one day, with the exception of one thyroidectomy, which developed acute hyperthyroidism after operation.

There is, no doubt, a large mental factor involved in vomiting, and some patients will vomit even after a simple nitrous oxide anæsthesia. Further, in a children's hospital where this new anæsthetic was given, it was found to be quite exceptional for a child to vomit after it was conscious, except in the case of prolonged excision of cervical gland operations where the vagus was disturbed. The sisters of the surgical wards of this hospital were unanimous that the children were, on the average, much fitter after this anæsthetic than after chloroform or ether which had previously been used, and that the vomiting was very much less.

FIG. 1.—*Diastolic Blood Pressure.*

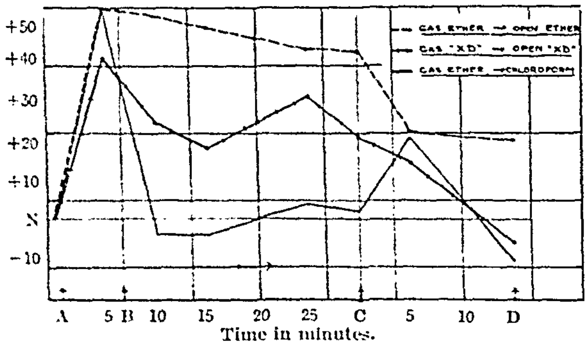


N = normal. A = induction started. B = operation started.
C = operation finished. D = patient conscious.

(*b*) *Respiratory Complications.*—None have occurred, with the exception of the one case mentioned above.

(*c*) *Taste and Smell of Anæsthetic.*—These are practically non-existent, and constitute one of the main advantages of the anæsthetic. Patients who have been previously anæsthetised with ether, and have objected to these after-effects, have invariably experienced surprise at their absence with this anæsthetic.

FIG. 3.—*Pulse Rate.*



I have quite lately anæsthetised a doctor, a hospital nurse, and an army officer, who had all previously had ether and complained of continual vomiting (in one case up to a week), and also of the unpleasant taste and smell. All three patients stated that there was no taste or smell on coming round, and none vomited after regaining consciousness.

No other complications attributable to the anæsthetic have been observed.

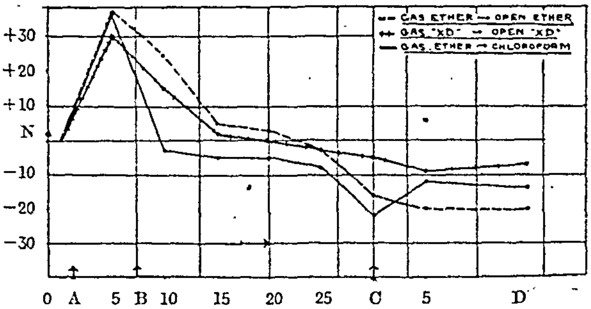
Method of Administration.

I have employed four main methods of administering this anæsthetic.

1. *Induction by a Clover's Inhaler, followed by an Open Mask.*—This method is suitable for most adult cases. Nitrous oxide gas may be used in the induction, but is almost unnecessary, as the vapour of the anæsthetic is not unpleasant to the patient. I have usually changed over to the open method just after the skin incision has been made.

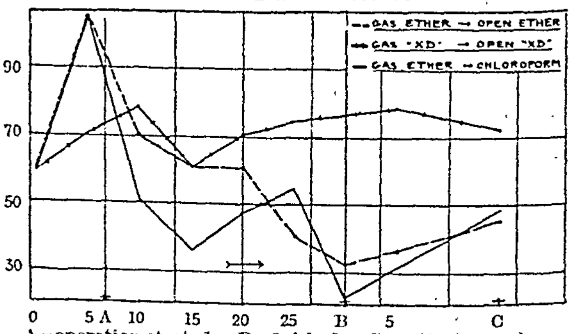
2. *Open Ethyl Chloride Induction, followed by the Anæsthetic on an Open Mask with 20 Layers of Gauze.*—This method is suitable for children up to 13 years old. I first of all put a few drops of tincture of orange on the inside of the gauze mask. When the child has got used to the smell I gradually spray on the ethyl chloride. Directly he is unconscious I change over to this anæsthetic and pour it on quite rapidly. This can be done without any coughing or salivation, such as occurs with ether. When completely anæsthetised it will be found that less anæsthetic is usually required than with ether. The time of induction is short by this method, the average being four minutes, until the patient is ready for an incision.

FIG. 2.—*Systolic Blood Pressure.*



3. *Combined with Nitrous Oxide and Oxygen.*—I have usually given this in a Boyle's machine, with the following modifications: (*a*) The two-way tap on the ether bottle is replaced by a special tap recently described by Mr. H. E. G. Boyle, which allows any percentage of the gases to pass through or over the liquid; (*b*) the bottle containing the anæsthetic is kept standing in a receptacle of warm water in order to prevent freezing taking place. Very good relaxation can be obtained with this method, and such operations as cholecystectomy, ileo-sigmoidostomy, and partial colectomy have been done with it. The time of recovery is usually very rapid, and for this reason the anæsthetic should be continued until the last suture has been inserted and tied.

FIG. 4.—*Pulse Pressure.*



A=operation started. B=finished. C=patient conscious.

4. *Intra-Tracheal Insufflation.*—I have employed this method for the following classes of operations: (*a*) Extensive thoracotomies, when both pleural cavities may be opened simultaneously; (*b*) operations on the upper abdomen, such as cholecystectomy or gastro-enterostomies, in which it is desirable to limit the respiratory movements as much as possible; (*c*) in operations on the neck where respiratory obstruction is anticipated, such as thyroidectomies, where there is a retrosternal lobe; (*d*) in plastic operations of the face.

I started by using the anæsthetic in the usual way, instead of ether by blowing pure air over it, but I found that better results were obtained by using it with gas and oxygen. I have connected the exit pipe of a Boyle's machine to the intra-tracheal apparatus, and have found that much less anæsthetic is required, and that with this method the patients appeared to be in better condition afterwards.

For all these methods the patients were given an atropine injection. Morphia was not given unless the patient was very excitable or nervous, as in my opinion it tends to mask the useful signs, such as eye reflexes, and is best given just before the patient regains consciousness, as he will then remain analgesic for a longer period.

Analysis of Results.

About 250 cases have been anæsthetised so far [at the time of going to press, this number has increased to 500], and I have detailed reports on the first 200. These were nearly all hospital patients, the majority being at St. Bartholomew's Hospital and the Queen's Hospital, Bethnal Green.

I have divided the quality of anæsthesia into three groups: (A) Anæsthesia very good, with no salivation, straining, or any other difficulties whatever. These constitute 91·3 per cent. (B) Anæsthesia satisfactory, but slight difficulty, such as some rigidity or salivation. These cases were 8 per cent. (C) Anæsthesia poor or great difficulty experienced. Only one case comes into this class, which was a child with myxœdema.

In no case has a change had to be made to another anæsthetic. In cases in which the open method has been used the time elapsing between the end of the anæsthetic and consciousness being regained is, on the average, about two-thirds of the length of time that the patient was anæsthetised. If given with gas and oxygen the time is about one-third. The average time of induction for all cases was 4·1 minutes.

The age of the patients varied between eight hours and 70 years, and the time of operation between 5 minutes and 2 hours 45 minutes. The first 100 cases were selected to give as representative a series of operations as possible. The remainder were not selected, being just routine hospital cases.

The operations performed under this anæsthetic include: Amputation through thigh (4 cases), appendicectomy (21 cases), appendicostomy, arthrodesis, astragulectomy, bone plating, *cholecystectomy* (3 cases), cholecystotomy, colectomy (partial), colostomy, cystoscopy, colopexy, excision of glands, excision of hæmorrhoids, exploration of knee-joint, exploratory laparotomy, gastrectomy (partial), gastro-enterostomy, Halsted's operation on the breast, ileo-sigmoidostomy, nephro-lithotomy, œsophagectomy (partial), osteotomy, radical operation for inguinal, femoral, and umbilical hernia (24 cases), reduction of intussusception, sequestrotomy, skin graft, sigmoidoscopy, submucous resection of nasal septum, suprapubic cystotomy, suture of perforated gastric ulcer, tarsectomy, tendon transplantation, thoracotomy, thyroidectomy (8 cases), thyroid graft, tonsillectomy, wiring of fractured patella.

None of the above cases gave rise to any anxiety during anæsthesia, with the exception of a long gastrectomy on a woman in very poor condition. At the end of two hours she became collapsed from loss of blood, but a blood transfusion was performed, and she greatly improved. This case made an uninterrupted recovery.

For the long abdominal cases in this list I have always adopted the method of getting the patients deep at the start, and then when the abdomen is opened and the anastomosis or other manipulations are being performed, of allowing them to become quite light, again giving more anæsthetic when the abdomen is being closed. The patients are in better condition at the end of operation, and much less anæsthetic is used than if a uniform depth of anæsthesia is maintained throughout.

Detailed Cases.

I will now describe some of the more striking cases in greater detail:—

CASE 4. Female, aged 69, suffering from severe chronic bronchitis, was very stout, and had a large umbilical hernia which was giving her trouble as it became semi-strangulated. She was given the anæsthetic combined with gas and oxygen. The operation lasted just an hour. Relaxation was good, and the patient recovered consciousness five minutes after cessation of the anæsthetic. The bronchitis was not apparently increased and she made a good recovery.

CASE 5. Male, aged 60, suffering from a perforated gastric ulcer. The diagnosis had not been made for some *days; when seen he was practically moribund*, and the radial pulse was not palpable. It was decided, however, that a laparotomy was justifiable to give him a chance. He was anæsthetised with gas and oxygen and this anæsthetic; breathing and colour considerably improved; a flicker was detected in the radial artery. The operation lasted 20 minutes during which time a solution of gum saline was infused intravenously. He recovered consciousness 20 minutes afterwards and lived for 24 hours, finally dying from peritonitis.

CASE 7. Male, aged 43, suffering from carcinoma of the colon, was given the anæsthetic combined with gas and oxygen, and a nearly complete colectomy and anastomosis was performed. The operation lasted 1 hour 25 minutes, and the patient was somewhat collapsed from loss of blood. A saline was given per rectum and he rapidly improved. He was conscious 20 minutes from the end of the operation, and had no vomiting or other after-effects from the anæsthetic.

CASE 25. Male, aged 14, had bilateral acute mastoiditis; was very ill, temperature 104°F., pulse 110, respirations 35; signs at both pulmonary bases. Was induced with the anæsthetic in a Clover's inhaler, and then on an open mask. Both mastoid antra were opened up; the operation was very difficult lasting 2 hours 10 minutes. The patient regained consciousness one hour after the operation, slept all night, and awoke next morning feeling quite fit and read a newspaper No vomiting or after-effects; signs at bases of lungs rapidly cleared up, and the temperature, pulse, and respiration soon fell to normal.

CASE 28. Male, aged 61, a diabetic, passing large quantities of glucose and acetone bodies in his urine. Gangrene of foot and very calcareous arteries; the femoral distinctly visible throughout its course in the skiagram. Anæsthetised with the liquid first in a Clover's inhaler and then on an open mask. The femoral artery was first ligatured, and the amputation then made through the thigh. The operation lasted 15 minutes. Half an hour afterwards patient had regained consciousness, was not sick, and felt very fit. He had no after-effects whatever.

CASE 31. Female, aged 44; ulcer in œsophagus thought to be carcinomatous. Intratracheal anæsthetic given, and portion of œsophagus containing ulcer excised through an incision in the neck; operation lasted 1 *hour 55 minutes*, and beyond one vomit of blood, which had trickled down into the stomach, the patient had no after-effects from the anæsthetic.

CASE 51. Female, aged 45, admitted to hospital with heart failure. When improving slightly cholecystitis developed and became worse in spite of treatment. It was therefore decided to operate. Patient then had auricular fibrillation, evidenced by grossly irregular pulse, dyspnœa, and some cyanosis. I gave her the anæsthetic combined with gas and oxygen, which she took very well and was completely relaxed. A cholecystectomy was rapidly performed, the operation lasting 25 minutes. The patient made a very good recovery and her heart was apparently in exactly the same condition as before operation.

CASE 118. Army officer, wounded in leg, who had had many previous operations under ether. Each time he had been very upset by the anæsthetic, had vomited for some days, and complained greatly of the taste and smell. I induced him with this anæsthetic in a Clover's inhaler, and continued by the open method. The operation lasted half an hour. As he was coming round and before he was conscious he retched and brought up some mucus. Soon after he regained consciousness he had tea and felt very fit. He had no vomiting and said he could not taste or smell anything, and expressing great surprise that this was so.

CASE 113. Male, aged 60, brought to hospital with acute cholecystitis; in a very bad condition, pulse 110, respirations 38. Much bronchitis; apex beat in sixth space well outside nipple line; also passing large quantities of sugar. Operation was imperative and it was decided to give this anæsthetic combined with gas and oxygen. He took it very well; on opening the abdomen an empyema of the gall-bladder was found; the operation lasted for three-quarters of an hour, patient regained consciousness in seven minutes, and did not vomit or suffer from any after-effects. The bronchitis was not increased, and he made a good recovery.

CASE 177. Female, aged 32, who had previously had a gastro-enterostomy for gastric ulcer; as the trouble recurred it was decided to do a gastrectomy. She was anæsthetised with this anæsthetic combined with gas and oxygen, and good relaxation was obtained; operation very difficult owing to adhesions from the previous gastro-enterostomy, and lasted 2 hours 40 minutes. At the end of two hours she was becoming slightly collapsed and a gum saline infusion was given intravenously. Her condition then greatly improved, and remained good until end of the operation. After recovering consciousness the patient vomited four times, the material being blood in each case. She had no further vomiting and made a good recovery.

Summary.

To recapitulate the advantages claimed for this anæsthetic:—

1. It is less toxic than chloroform or ether, and the safety margin is greater than with either.
2. It is less irritating to the respiratory passages than ether, and consequently there is less risk of subsequent bronchitis and pneumonia; the induction of anæsthesia is also rendered easier.
3. Post-anæsthetic vomiting is less than with chloroform or ether.
4. The taste and smell noticed afterwards by the patient are very much less than with ether, and are generally entirely absent.

In conclusion I should like to express my thanks to those surgeons who have afforded me opportunities for taking blood-pressure readings, and to Mr. B. B. Sharp, late resident anæsthetist to St. Bartholomew's Hospital, for his help in taking the readings.

CHAULMOOGRA OIL IN LEPROSY AND TUBERCULOSIS.

THE SUCCESSFUL TREATMENT OF LEPROSY BY INJECTIONS OF SOLUBLE PREPARATIONS OF THE FATTY ACIDS OF CHAULMOOGRA AND OTHER OILS AND ITS BEARING ON THE TUBERCULOSIS PROBLEM.[1]

BY SIR LEONARD ROGERS, KT., C.I.E., M.D., F.R.C.P. LOND., F.R.S., I.M.S.,
EXTRA PHYSICIAN FOR CLINICAL RESEARCH, LONDON SCHOOL OF TROPICAL MEDICINE.

ALTHOUGH the disease of leprosy is mainly of historical interest in this country, it presents an important and difficult problem in the tropics, especially in India and China; so a method of treatment which brings about destruction of the leprosy bacilli in the tissues is thus of great interest apart from its possible bearing on tuberculosis. Chaulmoogra oil has long been the best known remedy for the disease, but, owing to the nausea produced by large doses, it has only an ameliorative effect in typical cases, although Hopkins of Louisiana obtained some apparent cures in incipient cases by persevering with use of the oil. In 1913 Heiser reported apparent cures of a few cases by the prolonged use of chaulmoogra oil intramuscularly, which was a distinct advance. Power and others had obtained chaulmoogric and hydnocarpic acids from chaulmoogra oil and from hydnocarpus oils, while the name of gynocardic acid had been given by Moses to a mixture of the lower melting-point acids of chaulmoogra oil.

Use of Gynocardic Acid.

I myself early used gynocardic acid orally in the place of chaulmoogra oil with promising results, one severe case having nearly cleared up on very large doses in the course of a year, and in 1912 I attempted unsuccessfully to obtain a soluble compound of it for injection; returning to the subject in 1915, after Heiser's results had been published, I began giving subcutaneous injections of sodium gynocardate, which resulted in more rapid improvement than that following the oral use of gynocardic acid. These injections, however, were rather painful and slow in their action, so I next used sodium gynocardate intravenously in small doses, which were painless, being followed in some cases with much thickening of the tissues, indicating the presence of very large numbers of acid-fast bacilli, by febrile reactions accompanied by swelling up and softening, with subsequent more rapid absorption of the lesions. Microscopical examinations in such cases showed large numbers of red dots of disintegrated bacilli with but few remaining rods, proving that the reactions resulted in rapid destruction of the bacilli in the tissues. Repeated microscopical examinations of cases not showing febrile reactions demonstrated that a similar more gradual breaking-up and absorption of bacilli occurred under the new treatment, until the lesions became bacteriologically negative.

Occasionally, in advanced cases of the disease, more severe reactions with prolonged fever occurred, followed as a rule by great improvement. Two remarkable cases were noted, in one of which extensive lesions of 20 years' duration with ulceration almost completely cleared up, with healing of all ulcers, during a period of about a year following a single small intravenous injection with prolonged febrile reaction; whilst in the other case very extensive lesions on the face and body completely disappeared, becoming bacteriologically negative after a similar reaction, although no further injections were given—a fact indicating that the extensive breaking-up of the bacilli during such reactions had led to curative formation of antigens in the body. Such reactions took place only after intravenous, and not after subcutaneous, injections of sodium gynocardate; the improvement was also much more rapid and satisfactory under the former method of administration, although it had the drawback that irritation of the vein at the site of injection sometimes caused strictly local obliterative phlebitis, producing difficulty in continuing the intravenous injections in certain patients.

Activity of Hydnocarpic Acid.

The next step in the investigation was to separate different melting-point unsaturated fatty acids of chaulmoogra oil by fractionation, and to test their sodium salts or soaps in cases of leprosy, to ascertain which were most active in the disease. As the result of prolonged observations it was found that the lower melting-point preparations, consisting mainly of gynocardate of soda, were less active than those made from fractions with melting-points of about that of hydnocarpic acid—namely, 58° C.; but that chaulmoogric acid, with a melting point of 68° C., formed sodium salts too insoluble for injection alone: the latter could be used in combination with sodium gynocardate, but without presenting any advantages. The conclusion was, therefore, arrived at that hydnocarpic acid was probably the most active constituent of the oil; it can be obtained more readily and in large quantities from hydnocarpus oils than from true chaulmoogra oil derived from the seeds of the Indian tree, *Taraxtogenos kurzii*. Later observations, however, have shown that active preparations can be made without laborious fractionation, from the whole of the fatty acids of these oils, which will simplify the production of the soluble active portions of the oil for the new injection method of treating leprosy.

Use of Sodium Morrhuate in Tuberculosis.

The successful treatment of leprosy by soluble derivatives of chaulmoogra oil led me to consider the trial of a similar line of treatment in tuberculosis, due to the other important human acid-fast bacillus, but the induration, pain, and slow effects of subcutaneous injections of gynocardates, and the severe febrile reactions sometimes produced by their intravenous injections, which might conceivably lead to a generalised infection, made me hesitate to use that preparation in tuberculosis, so I made a similar sodium salt of the unsaturated fatty acids of cod-liver oil, which I called sodium morrhuate, and first tested it in leprosy cases which had become stationary on gynocardates, or in which the latter could not be given intravenously for any reason. The preparation proved to be non-toxic, very soluble and unirritating to the tissues or veins, so was much easier to administer than the gynocardates and hydnocarpates; it soon became evident that leprosy patients who had ceased to improve on gynocardates might once more progress and completely clear up under sodium morrhuate. Moreover, even advanced cases treated by simple and almost painless subcutaneous injections of sodium morrhuate might recover completely; the very important fact was established that other oils besides chaulmoogra and hydnocarpus may be effective in leprosy.

---

[1] An abstract of a paper read before the Section of Therapeutics and Pharmacology of the Royal Society of Medicine, April 19th, 1921.

Testing of Other Oils.

A wide field of investigation was thus opened up and explored; oils with a high iodine value, indicating a large content of unsaturated fatty acids, were selected for testing. One made from linseed oil proved to be irritating to the tissues, while another derived from Japanese sardine oil was very toxic to animals, but a third preparation made from soya bean oil, which is an excellent food largely used in China, was found to be very suitable for injection purposes. In a short trial before the author left India, a severe case, with a very extensive lesion on the face, cleared up and became bacteriologically negative within the exceptionally short time of six weeks; proving that yet another oil may yield active products, although further cases did not clear up so rapidly. These several preparations may be advantageously used alternately or mixed together, a change being made if progress is not satisfactory under one of them.

Duration of Treatment.

The duration of treatment required to obtain complete clearing up of typical leprosy cases is considerable, a year or more often being necessary, although comparatively early cases may show apparent recovery in a shorter time. The results of five years' investigation were summarised at the Calcutta Leprosy Conference in February, 1920, when of 51 cases treated with sodium gynocardate and hydnocarpate, 1 was not improved, 9 slightly improved, 20 greatly improved, and in 21 the lesions had completely disappeared, all cases treated as long as three months being included. Thus, 80 per cent. showed either great improvement—with a good prospect of complete clearing up after further treatment—or had already become bacteriologically negative. If cases treated for a year or longer were considered alone, 9 out of 13, or 65 per cent., showed complete disappearance of the lesions. Of 20 further cases treated with sodium morrhuate, 3 were slightly improved, 12 greatly improved, and in 5 the lesions had disappeared, none of the cases having been treated for over one year; 85 per cent. were thus classed as greatly improved, or "lesions disappeared."

After-Results.

The after-results were next discussed in the light of 26 gynocardate and 8 morrhuate cases, which had been followed up for another year subsequent to an earlier report on their condition. Of the former class, 5 had shown further improvement, in 5 the lesions had disappeared, and 10 remained well, bringing the latter class up to 65 per cent.; 5 had relapsed—all patients who had discontinued the treatment against advice as soon as their visible lesions had disappeared, although some of them subsequently cleared up again under further treatment. Stress was laid on the importance of relapses in emphasising the necessity for prolonged treatment and justifying the caution of the author in not speaking of cures. Still, four cases had remained well for two and a half years, and six more for over one year; in certain of these cases an additional year can now be added, so that some may eventually prove to be cured. Confirmatory results reported by a number of observers were quoted, the most important being a trial in 13 Indian leper asylums of hydnocarpates in 183 and morrhuate in 117 cases reported on by Dr. E. Muir (who is now carrying out much more extensive trials in connexion with the Calcutta School of Tropical Medicine) with improvement in 72 per cent. and great improvement in 32 per cent. The trials were only of from two to 12 months' duration in most of these cases; while of those treated for six months and over, 100 per cent. showed improvement and 52 per cent. great improvement, including disappearance of the lesions in some cases. Moreover, sodium morrhuate gave exactly the same results as hydnocarpate of soda. Dr. M. Carthew, in 14 cases followed up in a Siam jail, also reported 2 improved, 8 greatly improved, and 4 with lesions disappeared for from six to 18 months. Ethyl ester chaulmoogrates and morrhuates were also made, but the former was rather painful on injection, although it has the advantage that it can be given subcutaneously or intramuscularly; in the Sandwich Islands, Hollmann and Dean, in 1919, and McDonald, in 1920, have reported very good results from its use, 78 patients having been discharged on parole by a medical board by the latter date. Moreover, patients were voluntarily seeking admission to the leper hospital for treatment, which should help in the segregation of early cases. There is thus no doubt that a great advance has been made in the treatment of leprosy by the researches in Calcutta and those of more recent date in Honolulu.

Age and Susceptibility to Leprosy.

Figures were next adduced to show that there is an especial susceptibility to infection by leprosy during the first two decades of life as compared with later decades. Denny, in the Philippines, has shown that no less than 44 per cent. of children living for seven to ten years with leper parents became infected, and that no less than 73 per cent. of cases in which the source of infection was traced, were among children and young adults, as compared with 1 to 2 per cent. between husband and wife in later decades of life. The frequent infection of children with tuberculosis is closely parallel, and attention was drawn to a recently published report showing the success of the Grancher Institute in Paris, which by permanent removal of children from exposure in overcrowded families containing adults with open tuberculous lesions, has greatly lessened infection among children. The great value of such protection of early life against infection of both leprosy and tuberculosis was emphasised.

Variable Results in Tuberculosis.

The trial of sodium morrhuate and sodium gynocardate in tuberculosis was next dealt with, the use of the former by six medical men in India having been reported in 1919, when the author concluded that the treatment was harmless and worthy of further trial, in view of five out of the six observers having reported favourably. Since that time variable results have been recorded, a trial among Indian sepoys in the dry, cool climate of Quetta having been very favourable, as well as the use of sodium morrhuate in tuberculous gland cases and in four cases of lupus, in one of which a new preparation, mercury morrhuate, was applied locally. On the other hand, trials in America had not given favourable results in phthisis. Attention was next drawn to the remarkable experimental investigation of gynocardates and morrhuates on acid-fast bacilli by Walker and Sweeny, who found that the chaulmoogra-oil preparations were lethal to acid-fast bacilli as a class on long exposure to their action in fluid media in dilutions of 100,000, having an especial selective action on them, although not on other classes of bacilli: they suggested that in leprosy these soluble preparations of chaulmoogra oil might have a direct destructive effect on the leprosy bacillus. On the other hand, sodium morrhuate had no such action on a fast bacilli, and I wish to point out that the interesting American observations do not explain the undoubted value of sodium morrhuate in leprosy; and that some chemical reaction with the fatty envelopes of the acid-fast bacilli, so weakening them as to allow the body cells to deal with them, best accounts for their destruction in the body under the action of my preparations; but much more research is required in the wide field now opened up.

Conclusion.

A recent experimental investigation has been made of the three new preparations, which had proved effective in the treatment of leprosy, in animals infected with tuberculosis; but in the acute general tuberculosis produced in the very susceptible animals used the results were entirely negative, except for an early febrile reaction followed by temporary fall of temperature, in two goats, who eventually succumbed to the infection at about the same time as a control animal. It was pointed out that these animal infections were equivalent to acute general tuberculosis in man, so that the failure in such cases did not prove the drugs to be useless in the more chronic forms of tuberculosis which form the great majority of human cases. I conclude that, whilst there is doubt at present as to the advisability of treating pulmonary tuberculosis with sodium morrhuate, except in the hands of experts with control cases, these drugs are worthy of further trial in the more chronic forms of the disease, and especially in lupus and surgical tuberculosis, where any changes will be visible and easily observed.

A CASE OF JAUNDICE FROM LATE SALVARSAN POISONING.

BY JOHN ELLIOTT, O.B.E., M.D., B.S., B.SC.LOND., F.R.C.S. ENG., F.R.C.P. LOND.,
PHYSICIAN, CHESTER GENERAL INFIRMARY.

IN September, 1918, I was asked by a colleague to see a patient who was suffering from locomotor ataxia with severe root pains; he had previously had two intravenous injections of salvarsan with inunction of mercury administered. The second injection was followed by violent vomiting and purging and alarming general symptoms. At that time I was in the habit of administering novarsenobillon by the "deep subcutaneous" method into the fascia covering the gluteus medius. As I had seen no untoward effects from this procedure I concluded that the slower rate of absorption of the drug made for comparative safety. Accordingly I administered 0·45 g. by this method dissolved in a few minims of distilled water. It caused no pain and he went to business the same day and also on the next day. On the evening of this day, however, he was taken ill with vomiting and purging, the stools containing blood. The illness lasted two days. As the injections gave him great relief from the lightning pains I decided to repeat them, guarding (if possible) against after-effects by the administration of adrenalin chloride (1 in 1000) ♏ 25 in water twice daily, with intermediate doses of calcium lactate, gr. 20, commencing on the day of injection and continuing for three days. This procedure was completely successful; the injections caused practically no pain (no doubt due to the diminished deep sensibility from tabes), and he suffered neither discomfort nor malaise but continued his work uninterruptedly. Since that time I have given him several prolonged courses of novarsenobillon and inunction of mercury ointment, always with the accompanying medicinal treatment as above, and with marked benefit to his condition.

In the course of the three years during which I ve been connected with the venereal clinic at the ster Royal Infirmary I had seen no case which gave me the slightest anxiety from after-effects, with the exception of one very severe case of acute dermatitis, which came to us after treatment at another clinic, and the case of jaundice which I am about to describe—and this in spite of the fact that many of the patients live in the mountainous districts of Flintshire and Denbighshire, and have to travel to their homes after receiving an injection. I make it a rule never to give an injection if the patient is not in good health, from any cause other than his specific complaint. The urine is tested before each treatment, and all patients undergoing a course of salvarsan and mercury treatment take a teaspoonful of sublimed sulphur in treacle or syrup at bedtime to assist in the elimination of the mercury and thus also, indirectly, of the organic arsenic compound. They are also encouraged to drink freely of simple diuretics such as barley water or whey. I had seen no case of jaundice from delayed salvarsan poisoning, but decided that I would treat such a case with intravenous injections of normal saline (which I had found efficacious some years ago in treating a case of acute yellow atrophy), and also with adrenalin and calcium, after my experience of the effect of these drugs in the case of tabes mentioned above.

On Jan. 22nd of this year a patient attended the clinic with the following history:—

A man, aged 39, employed on a farm. Rheumatic fever in 1913; laid up 12 weeks. Joined army February, 1918; served in the R.E. in Kent; never abroad. Had a venereal sore when he joined army; slight rash on the arms, no sore-throat; had no treatment.

1919.—Glands in the neck enlarged; discharged from army on this account. May to September, 1919, in Chester Royal Infirmary. Lymphadenoma diagnosed; treated with arsenic and X rays; no improvement. July 21st, 1919, Wassermann test positive +; treatment, potass. iodid. and mercury ointment inunction; lost sight of until March, 1920, when he appeared at the venereal clinic. March 20th, 0·45 g. novarsenobillon intravenously, inunction; 27th, not well, injection omitted. April 3rd, 0·45 g.; 10th, omitted. 17th, 0·6 g.; 24th, 0·6 g.; May 8th, 0·6 g.; not well after the injections; these omitted until June 5th, 0·45 g. June 12th, 0·45 g. Injections discontinued again; 24th, Wassermann positive + +. July 28th, 0·45 g. August 4th, 0·45 g. August 11th, 0·6 g. and hyd. 1 gr. intramuscularly. 18th, 0·6 g. Sept. 1st, 0·6 g. and hyd. 1 gr. 8th, 0·6 g., hyd. 1 gr. 25th, 0·6 g. and hyd. 1 gr. Oct. 2nd, 0·6 g., hyd. 1 gr. 9th, not well. 16th, 0·6 g. 23rd, Wassermann positive + +. Nov. 20th, 0·45 g., hyd. 1 gr. 27th, 0·6 g., hyd. 1 gr. Continued to attend at the clinic, but felt unwell.

He always felt ill after the injections; shivering, giddiness, sometimes sickness, feeling of prostration and distaste for food. The specific treatment was entirely discontinued and tonics were administered from time to time. It is noteworthy that intramuscular injections had the same effect as those given intravenously.

Jan. 22nd, 1921: Came to the clinic complaining that he had been vomiting after everything he took; had noticed that he was yellow. Pain coming and going in the stomach; urine had been a deep colour. At once admitted as an in-patient; put on low, fat-free diet; sulphur, a teaspoonful at bedtime, and barley water ad lib. Did not vomit during the first two days in hospital. 24th: 4.30 P.M., one pint of normal saline given intravenously. 6 P.M., severe rigor, patient faint and collapsed; 6.30 P.M., hæmatemesis, about 5 oz. bright blood vomited; diarrhœa; severe pain in epigastrium and under right ribs, shooting to back and up right side. Temp. 103·4°F., pulse 128. 9 P.M., I saw him at the infirmary; deeply jaundiced, pulse 110; collapsed and feeling very ill; right upper rectus abdominis rigid; tenderness in epigastrium and over gall-bladder region. Gall-bladder could be felt distended; spleen not felt; liver dullness normal. (I formed the opinion that the gall-bladder was distended with blood.) Ordered liq. adrenalin chlorid. ♏ 25, and calcii chlorid. 10 gr., in alternate doses 4 tis. 25th: Much better, no further vomiting or diarrhœa; pain not so severe; 20 oz. of dark-coloured urine had been passed during the preceding 24 hours. Fæces clay-coloured. 26th: 10 oz. normal saline, given intravenously; slight shiver followed and temperature rose to 99°. Gall-bladder diminished in size, liver and spleen normal, less pain. (The distilled water used in preparation of the normal saline was not above suspicion, so I had it doubly distilled, and no further ill-effects followed the injections.) Saline administered per rectum in addition to the intravenous. 27th: 10 oz. saline intravenously; the same quantity per rectum;

amount of urine increasing; 40 oz. passed. Herpes on upper lip; pain still on and off. 28th: saline as before, pulse 62. Jaundice unaltered; patient felt drowsy. Gall-bladder still palpable; urine gave iodine reaction for bile pigment for first time. No albumin at any time; urine 30 oz.; no leucin or tyrosin. 29th: vomited; no blood. Still drowsy; jaundice decreasing. On the 30th all treatment was intermitted for one day; on the 31st saline (one pint) was given intravenously; half pint per rectum, followed by increased excretion of urine: 40, 57, 45 oz. on succeeding days.

Adrenalin and calcium stopped on Feb. 1st. Jaundice gradually disappeared, drowsiness diminished, urine and fæces became normal, and patient completely recovered. Nothing could be felt of liver, gall-bladder, or spleen. I may mention that the enlarged glands in the neck, which had begun to decrease in 1919, had disappeared when he returned to the clinic in 1920. Wassermann test, March 22nd, 1921, positive + +. I was somewhat disappointed to find that the severe experience through which he had passed had left the blood reaction unaltered. In the face of such a marked positive reaction as this it would be wrong entirely to discontinue active specific treatment, and I propose to order thorough treatment by inunction of mercury, combined with the dose of sulphur each day, send him into the country for a month to re-establish his general health, and then admit him to hospital for a complete course of salvarsan and mercury treatment under observation, guarded by the adrenalin and calcium dosage as in the case of tabes recorded above. *Under these circumstances it will be possible to* keep under observation the effect of the injections and the efficient working of the kidneys.

Remarks.

There can be no doubt that this was a case of late jaundice from salvarsan poisoning, the interval between the last injection and the onset of symptoms having been about 42 days. The symptoms are identical with those recently recorded in similar cases by Major A. T. Todd.[1] I have seen no record, however, of a distended gall-bladder such as existed in this case, my surmise that the distension was caused by effused blood, with blocking of the cystic duct by clot, being probably correct. Had I carried out my original intention of commencing the treatment with adrenalin and calcium the alarming collapse of the *evening of Jan.* 24th would almost certainly have been avoided. The hæmorrhagic symptoms showed that the effect of arsenic on the capillaries, and probably also on the blood, had been reinforced by the dilution of the blood with the normal saline injected. My confidence that administration of adrenalin and calcium would render the subsequent intravenous use of saline a safe procedure was abundantly justified by the further course of the case. The diuretic effect of the saline was very evident, and there can be no doubt that it assisted materially in the elimination of the poisonous toxins. A marked feature of the case was the reaction which followed each injection of salvarsan, and the feeling of malaise and illness which induced us to intermit the treatment from time to time, and, fortunately, to discontinue it between Nov. 27th and the onset of the acute illness in January.

Major Todd,[2] from estimation of the ratio between ammonia nitrogen and urea nitrogen, concludes that "at some time during the acute stage of the illness acidosis was determined in 80 per cent. of the cases, and was present in all but the slight cases." No estimation of the urinary nitrogen was made in my case; the symptoms, however, do not seem to me to be similar to those caused by acidosis as we are familiar with it in uræmia and diabetic coma, there being no such disturbance of respiration. I am strongly of opinion that the grave symptoms are caused by the toxins set free by the destruction of the liver cells, and that, in the main, treatment should be directed towards their elimination. The intravenous administration of saline not only assists this object but also dilutes the toxins in the blood.

One of the most efficient and simple diuretics in my opinion is whey, and its use during a course of salvarsan and mercury treatment would, I think, be beneficial. The late Dr. Samuel J. Gee drew attention to its use in cases of stone in the kidney, and I have frequently had opportunities of verifying his observations.

In conclusion, I wish to thank Dr. W. J. A. Russell, house physician at the Chester Royal Infirmary, for the careful notes which he took of the case.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF PULSATING EMPYEMA.

BY SIR JOHN BROADBENT, BART., M.D.OXON., F.R.C.P.LOND.,
PHYSICIAN TO ST. MARY'S HOSPITAL, PADDINGTON.

THIS condition is so rare that I think the following case worthy of record.

M. S., aged 9, was admitted to St. Mary's Hospital on March 6th, 1921, on account of pulsating swelling in the præcordial area.

History.—She was well and attending school till Jan. 20th, when she had her tonsils removed at a local hospital. On her return home there was pyrexia, and she was kept in bed and attended by a doctor. A pulsating swelling was noticed on March 5th, and she was sent into hospital. No history of pneumonia was obtained.

Condition on admission.—Child looks very ill. Temperature 102° F., pulse 140, respirations 40. A pulsating swelling is seen in the præcordial area about 2 inches in diameter; its upper margin is at the left nipple, the lower at the sixth rib, its outer margin ¾ inch beyond vertical nipple line, the inner margin just at the left border of the sternum. The swelling projects about ½ inch from the chest and pulsates forcibly and synchronously with the heart. The apex beat of the heart cannot be felt, but the heart is not displaced to the right as the area of cardiac dullness does not extend beyond the mid-sternal line.

Lungs.—The whole of the left side of the chest is dull back and front. There is well-marked bronchial breathing back and front over the whole of the dull area, most intense over the upper lobe in front, where a few sharp crepitations are heard.

A diagnosis of pulsating empyema was made. An exploring needle was inserted below the angle of the scapula and pus withdrawn. An aspirator was then used, but only about 3 oz. of pus could be withdrawn as the child complained of great pain. The next day, the 7th, Mr. V. W. Low removed a piece of the eighth rib below the angle of the scapula and evacuated a small empyema, only about 4 oz. of pus escaping. The abscess cavity was small, and on its inner aspect the heart could be felt pulsating. The evacuation of this empyema had no effect on the pulsating swelling in the præcordial area. The next day the temperature fell to 99°, and the child seemed better, but there was still absolute dullness over the upper part of the left lung, with intense bronchial breathing and a few sharp crepitations. On the 12th, as the pulsating swelling still persisted, Mr. Low incised it and about 3 oz. of pus escaped. It was found to be an empyema pointing through the fifth intercostal space and encapsuled between the heart and chest wall. At the bottom of the wound the heart could be seen pulsating violently. This cavity was entirely shut off by firm adhesions from the abscess cavity of the empyema previously opened. A small rubber drain was put into the cavity, and was discontinued after three days as there was little discharge. The temperature after a few days settled down. The upper lobe of the left lung above the empyema became less dull and gradually expanded and the bronchial breathing was no longer heard. Both wounds healed rapidly and the child made an excellent recovery and was discharged from hospital April 22nd.

Dr. Joseph Sailer[1] in 1904 published a paper on "Pulsation of the Wall of the Thorax," in which he states that he has collected records of 97 cases in which effusion of fluid in the pleural cavity was associated with pulsation of the thoracic wall. He divides these into two main groups: (1) General diffuse pulsation of the wall of the thorax; (2) localised pulsating tumours. These he classified as follows:—

---

[1] THE LANCET, 1921, i., 632.

[2] Loc cit.

[1] Sailer: Journal of American Science, vol. cxxviii., 225.

Pointing empyemata	34	Localised pulsation.
Pyopneumothorax	4	
Diffuse general pulsation of thoracic wall	25	Diffuse pulsation.
Pyopneumothorax	8	
Circumscribed encapsuled empyemata ..	5	
Extrapleural abscess	5	
Serous or hæmorrhagic effusion ..	12	

In 53 cases of left-sided effusions the heart was displaced to the right.

In 58 out of 62 cases when locality of pulsation was mentioned it was on the left side.

Of the 97 cases 37 recovered, 27 died, and 16 improved; the history of the others was not known.

Explanation of Local Pulsation.

As Sailer states, it is clear (1) that the source of pulsation must be the heart, (2) that the pulsations must be transmitted through the collection of fluid to the surface.

Normally the pulsations of the heart are absorbed by the lung, and even if one side of the chest is full of fluid the pulsations of the heart are absorbed by the other lung, which is resilient, and are not transmitted through the fluid.

For pulsation to be transmitted through the fluid to the chest wall two factors appear to be essential: (1) The fluid must be shut off by adhesions and brought into close contact with the heart under a certain degree of tension; and (2) the heart and pericardium must also be fixed by adhesions, and thus kept in apposition with the fluid under tension.

In the case under consideration these conditions were fulfilled, as there was an empyema shut in between the heart and the chest wall pointing to the fifth intercostal space and pulsating, and the heart was fixed by adhesions, as it was not pushed over to the right in spite of the fact that there was another separate empyema at the left base. It is remarkable that the pericardium, being in such close contact with two purulent effusions, should not have been infected.

A CASE OF
WEBBING OF THE LEFT ARM.

BY J. S. MANSON, M.D.EDIN., D.P.H.,

MEDICAL OFFICER OF HEALTH, RUNCORN RURAL DISTRICT.

THIS rare condition is illustrated by the accompanying photograph. The skin fold on the left side extends from the nipple to the internal condyle of the humerus. The depth of the anterior axillary fold measured from the acromion process is 8¼ inches compared to 5 inches on the right side. The left humerus is 1 inch shorter than the right. The left pectoralis major is very poorly developed if not altogether absent. The pectoralis minor is also small. The scapular muscles seem less in size than those on the right, but are otherwise well developed. The arm cannot be raised quite to the level of the shoulder. The left side of the chest bulges in front at the junction of the costal cartilages with the ribs. There are no other abnormalities.

ROYAL SOCIETY OF MEDICINE.

SECTION OF MEDICINE.

ARTIFICIAL PNEUMOTHORAX.

A MEETING of this Section of the Royal Society of Medicine was held on May 24th, Dr. A. F. VOELCKER, the President, being in the chair, when Dr. CLIVE RIVIERE opened a discussion on Artificial Pneumothorax. Pneumothorax treatment of pulmonary tuberculosis, he said, had now been practised for over 30 years and its value was more and more widely recognised. The treatment was indicated, according to Forlanini, its most notable exponent, "every time that life is threatened by the extension of a local lesion." To achieve success with it, it was necessary to follow very closely its indications and contra-indications, the most important being concerned with the condition of the opposite or "better" lung. Disease in this might be fairly widespread, but must not be of decided activity. The condition of this lung could only be gauged after the deep parts had been revealed to X-ray examination. Râles on the "better" side were often conducted from the bad side, and would disappear when the bad lung was collapsed—care must be taken that this conduction did lead to error and the refusal of suitable cases. Refills of gas must not be too large, and hence must not be at too long intervals. 1000 c.cm. or more, often given in this country, were too large; 700–800 c.cm. should be the limit, and 500 c.cm. were safer. The intervals would be governed by the rate of absorption and vary considerably for different cases—no "standard" interval could be laid down. With the course of time a pleural sclerosis occurred and the gas pressure had to be raised or the lung would expand. This necessitated X-ray examinations at intervals during the course of a case. On the other hand, too high pressures would lead to mediastinal over-displacement, accompanied by unpleasant symptoms. A condition which tended to the undue raising of intrapleural pressure was the onset of pleurisy—very small quantities of gas raised the pressure very high. But no such gas should be introduced, nor the chest punctured till the acute stage was past.

The surgical treatment of adhesions preventing efficient collapse of the lung was an important line of progress. If few they might be divided, without opening the chest, by galvanocautery or tenotome. If more numerous the chest might be opened without rib resection and the adhesions divided. Separation of widely adherent lung had also been tried, but was not a hopeful operation. More hopeful, under such conditions, was a stripping of the costal pleura, and the packing of the space with fat or paraffin, or in some cases, the establishment of a pneumothorax between the costal pleura and the endothoracic fascia. There remained also extrapleural thoracoplasty, but for all these operations the case must be very carefully picked, particularly with relation to the condition of the "better" lung. The point to be specially insisted on in the treatment of pulmonary tuberculosis by pneumothorax or by surgery was the narrowness of the indications, but the striking hopefulness of the treatment within these limits.

Sir JAMES FOWLER described a case which had come under his notice in 1885, when artificial pneumothorax was induced in a youth aged 21 for hæmoptysis. The patient had been in hospital for 31 days, and during severe attacks of hæmoptysis 196 ounces of blood were brought up. After the pneumothorax the patient had two attacks of hæmoptysis during the five days he lived, during which 4 and 2 ounces of blood were coughed up. Post-mortem examination showed the presence of an old cavity at the apex of the left lung from which the blood had come, the upper lobe and the right lung being infiltrated with miliary tubercle. Sir James Fowler considered that pneumothorax was one of the two great advances which had been seen in the treatment of tuberculosis.

Dr. S. VERE PEARSON said that the more experience he gained the more he felt that too much diffidence was shown in resorting to artificial pneumothorax. He did not advocate it in early cases. After quoting two cases illustrating its value, he said that he agreed with other writers as to the impossibility of ascertaining by any means short of puncture with a hollow needle connected with a manometer, whether or not adhesions were present. The form of needle used for an initial operation was unimportant, and he believed in trying the simplest kind first. He had abandoned a great number of punctures when met by failure to find free pleural surfaces, and persistent endeavour by ordinary means when initially only a very incomplete pneumothorax could be produced on account of adhesions. He did not usually try again after two séances with about three punctures each. It was in the days, now several years ago, when he used to try to tear adherent pleural surfaces apart in cases with extensive adhesions by repeated doses of gas at high pressure, that he met with the only suggestion of gas embolism he had come across in his own practice. The patient became semi-conscious for a few minutes, and afterwards for several hours presented partial hemianopia and hemiparesis. With regard to pleural reflex, twice he had encountered alarming symptoms, which perhaps ought to be ascribed to this reaction, but the effects produced by a very small initial dose of gas, given with all the manometric readings favourable, hardly accorded with those usually ascribed to pleural reflex. The dose immediately set up most distressing dyspnœa of the asthmatic type. In the first case this subsided in a few hours. The hopelessness of the outlook unless compression treatment was successful induced him to make a second effort, but again the same symptom arose and took many hours to subside. In the second case the dyspnœa increased progressively unto death within an hour and a half after a dose of only about 100 c.cm. of oxygen. The gas was introduced on the advice of a consultant into the side containing the lung with least extensive disease, in the belief that this disease was that which was active, and that the outlook in any case was very bad.

In his series of cases of effective compression fluid occurred about as frequently on one side as the other, and in partial as in complete pneumothoraces. Of 56 cases, 23 had been right-sided and 33 left. Of the former, 8 were partial; 2 of these and 10 of the remainder had fluid. Of the latter, 7 were partial. Four of these partial ones and 14 of the complete pneumothoraces developed fluid at some time or other. A striking thing about the cases with fluid, if they were properly handled, was that the ultimate results were but little worse than those following dry pneumothorax. There were several points connected with fluid which might profitably be discussed. The fluid was generally at least a nuisance and often added a good many extra problems and difficulties in the management of the case. What were the circumstances which called for aspiration? Did replacement by oxygen instead of by nitrogen or air lead to quicker absorption? He had come to no final conclusions in either case. A chest full of fluid should be aspirated if possible. Such a cavity should be treated conservatively as long as it was purely tuberculous; this was almost invariable in these cases; it should not be opened by any cutting operation. When any fever, other than the slightest, persisted for many weeks and seemed to be caused by the pleuritis and the effusion aspiration should be resorted to, especially if malaise, anorexia, and indigestion were severe. If re-expansion of the lung was difficult to control and new adhesions seemed imminent, it was best to empty the chest as completely as possible and replace the fluid by gas. Under these circumstances one should not wait long, say only until the cavity was about one-third or one-half full, before repeating the procedure. Apart from the foregoing considerations he could see no advantages in aspirating the fluid. Whenever he aspirated he tried to get all the fluid off and replaced by gas. Fluid cases required more frequent reference to the X ray room than dry cases.

In England we were behind the continental workers in dealing with patients who presented all the indications of successful treatment by pneumothorax, but whose adhesions prevented success. He had been much impressed by Jacobaen's paper on the cauterisation of adhesions by the aid of the thoracoscope and a galvano-cautery. This author had operated by these puncture methods on 40 patients with partial adhesions. In 30 of the 40 he was able to accomplish what he had set out to do. In 26 he produced a more effective pneumothorax and thereby benefited the patient. With over 100 cauterisations he had never met with secondary infection and only once did hæmorrhage arise. There was incompetence from which patients suffered because of the hiatus between the physician and surgery—this must be bridged. For the division of partial adhesions, because purely tuberculous lesions were being dealt with, he favoured on theoretical grounds those methods which avoided, as far as possible, cutting operations.

Dr. NEVILLE COX referred to the danger of using a pointed needle for the first operation, and to the risks of tuberculin injections in the after-treatment. He thought that a matter of paramount importance to tuberculosis officers and others dealing with large numbers of phthisis cases, especially among the industrial classes, was the indications for the treatment, and whether it was justifiable to use it in some of the so-called early cases, pointing out the notoriously bad prognosis in such cases, where bacilli were persistently present, treated on ordinary lines. He also referred to the need of competent surgical assistance in some of the complications of pneumothorax, and thought that the larger sanatoriums should have properly equipped operating theatres, with surgeons attached, to deal with such cases.

Dr. DONALD HALL had been employing the treatment for two years—his only regret was that he had not employed it earlier, for he was absolutely convinced of its great merit. He thought that by the profession as a whole the treatment had not received the recognition which was its due. He urged that great care ought to be taken in the selection of cases, for although the patient might have nothing to lose, the treatment had, and therefore, until artificial pneumothorax was more widely adopted and approved, each avoidable unsuccessful case was an error in tactics on the part of its exponents. He now used air in preference to nitrogen. On four occasions he had made his first puncture with a Lillingston needle, but for first puncture he preferred the Riviere trocar. All his cases had been X rayed before and during treatment. He had found skiagrams of great help in determining the extent of collapse, but he would not be deterred by an adverse X ray report from undertaking a case the clinical physical signs of which were favourable. He had kept to low pressures, aiming at obtaining -5. His only unfavourable results had been cases in which. owing to adhesions. it had been impossible to produce more than partial collapse. So far he had met with no serious complications, such as perforation of lung, pleural shock, or air embolism.

Dr. JANE WALKER said that at the East Anglian Sanatorium patients had been treated by the method since 1912. The number of patients treated was 117, in 12 of which there had been failure to produce a pneumothorax. Those selected had been advanced cases in patients in whom there was little prospect of recovery, so that the percentage of "cures" was necessarily small. Artificial pneumothorax had been induced when there was evidence of general toxæmia, and when one lung only was extensively diseased, with a possible small lesion limited to about a fourth of the other lung. The treatment would not be employed if there were extensive disease in the other lung, if there were albuminuria, or if the patient were of a very nervous temperament. A small amount of disease in the other lung was certainly not a contraindication, and in a large number of cases, with the general improvement in the patient's condition, a diminution in the signs over the other lung had taken place. Of the 117 cases, 73 were of females and 44 of males. Their ages varied from 8 to 60. Sixteen under 16 years of age, 12 girls and 4 boys, and of them 11 had bacilli in the sputum, 4 sputum without bacilli, and 1 had no sputum. Nine of the 16 were alive, 1 treated in 1912, 4 in 1915, 1 in 1917, 1 in 1918, 1 in 1920, and 1 was now under treatment at the children's sanatorium. Of the remaining 101 cases, 37 were alive as far as was known; of these 16 had been treated by this method since the middle of 1920, and 11 of them had a very good prospect of recovery; 64 were known to have died, so that roughly two-thirds had died already, and a good many more were likely to follow.

So far there had been no serious accidents connected with the treatment; occasionally a vein had been punctured. The simplest possible form of apparatus was used, the only modification since 1912 being that for some years past air had been used rather than nitrogen. Oxygen had not been used for the initial operation. The patients were prepared by giving them omnopon a couple of hours or so before, and novocain or locæsthetic was used as a local anæsthetic, care being taken to anæsthetise the deeper tissues as well as the skin. On the first occasion 200–250 c.cm. were usually inserted, next day 300 c.cm., and then after a day's interval 350 c.cm., and so on, gradually lengthening the intervals. It had been the practice lately to give smaller doses at more frequent intervals, so that a patient was rarely allowed to go for longer than three weeks without a refill, and rarely as much as 1000 c.cm. were given for the first six months or so. The first few refills were usually finished with a negative pressure, and a pressure of + 10 was seldom exceeded later on. During the last four years X ray examinations had been made on all cases, and the presence of fluid had been detected in a large proportion. Prof. Saugman's estimate of 50 per cent. was not far from the mark. The disadvantages of a large quantity of gas were breathlessness, too great strain on the other lung, and digestive disturbances. It was a curious fact how difficult it was to make patients gain weight during treatment by this method. Dr. Walker felt very strongly that the time had come to consider whether this treatment should not be applied to cases before the patients became so seriously ill. On all the cases under consideration artificial pneumothorax was induced as a last hope, and although the percentage of recoveries was so comparatively low, still life for these people had been made far more tolerable. Distressing symptoms had been greatly alleviated and life prolonged, so that the procedure had been well worth while.

Dr. L. S. **BURRELL** said that he proposed to refer to two conditions which might arise during the treatment—one gradual obliteration of the pneumothorax cavity, the other the formation of pleural effusion. Out of 77 cases in which he had produced an artificial pneumothorax and had kept it up for a month or more, in five the air space had gradually become smaller until eventually it had closed. In one of these the parietal pleura became much thickened, so that the needle had to be introduced far to reach the air space, but in the other four there was no great thickening of the pleura. Having described these cases he said that in all of them the disease was on the left side, and each patient was over 30 years age. Treatment was started because of repeated moptysis in two cases, and because of progressive disease in spite of sanatorium treatment in the other three. The pneumothorax seemed to have hastened the formation of fibrous tissue, and all the cases had been much improved, in spite of the short time they were under treatment. He was of opinion that the treatment should be kept up for at least two years when possible, and he had seen a relapse follow four months after treatment had been stopped in a patient who had been having refills for 2½ years. Out of the 77 cases of artificial pneumothorax he had had 18 cases of pleural effusion, or 22·3 per cent., but he did not include among the 77 any case in which the treatment was not continued for at least a month. Of the 18 patients, in 11 the pleural effusion developed within the first four months of treatment, in another six it developed before the end of the eighth month, and in 1 after 19 months. Three were dead, three were very ill, but the remainder were doing well, and seven of them were at work. The fluid often became thick, and might contain tubercle bacilli, but no other organisms had been found in the series. He had noticed that patients from whom the fluid was not withdrawn often did quite well, and appeared to be unaffected by the effusion. It was his practice, however, to replace the fluid by air or oxygen about every three months.

Having demonstrated X ray prints obtained from a case of this kind, he spoke in favour of the double manometer, although he generally used the apparatus devised by Drs. C. Lillingston and S. V. Pearson. With a double manometer, as found in Dr. Parry Morgan's apparatus, the oscillations were more easily seen—a great advantage, especially at the initial operation. Moreover, with the double manometer, it was possible to know the pressure of the gas from the bottle and the intrapleural pressure at the same time. One could also discover by this manometer whether the gas was flowing into the pleural cavity.

Dr. S. **MELVILLE** said that he would plead for the collaboration of the clinician and the radiologist more in the induction of artificial pneumothorax than in most other things. (1) To determine the distribution of the disease. It was well recognised that the skiagram showed more extensive shadows of disease than were appreciable by physical examination. (2) In cases in which there was considerable disease in one lung there was speedily set up a compensatory emphysema in the more healthy lung, which unquestionably masked the physical signs. (3) To localise the position of definite adhesions with the possibility of indicating the most suitable site for inserting the needle. If a case were systematically watched during the intervals of filling, adhesions were seen which were unsuspected, and it was interesting to watch the slow but definite stretching of these adhesions. As the lung became decompressed they were seen to shorten—in other words, the lung expanded along the lines of the adhesions. In practically every case after a fair amount of gas had been introduced the other lung was seen to become less translucent. Attention had been drawn to this by Dr. G. Lucas, of Banchory. The conceivable therapeutic value of this change he ventured to emphasise, for although some of the lessened translucency might be due to compression, there was a hyperæmia set up which must have some influence upon any diseased focus in the more healthy lung.

SECTION OF OTOLOGY.

A MEETING of this Section of the Royal Society of Medicine was held on May 20th, Sir **CHARLES BALLANCE**, the President, in the chair.

The Pathology of Deaf-mutism.

Dr. J. S. **FRASER** (Edinburgh) showed a remarkable series of slides of sections of ears from deaf-mutes, demonstrating the structural defects. The contribution was based upon the examination of 130 children at a deaf and dumb school; also a number of cases at the Royal Infirmary, Edinburgh. Of the 130, 6 were instances of congenital aphasia, but they could all hear fairly well, one or two being able to obey instructions given in a whispered voice while their backs were turned. One child who could hear fairly well had deaf-mute parents. In 4 out of these 6 congenital cases the vestibular apparatus was normal. It was, he said, questionable whether a school for the deaf and dumb was the best place for educating children with congenital aphasia. Of the remaining 124 cases, 53 had congenital deafness, and in 13 others it was probably the case, too. Of the 53 definite cases the parents were blood relations in only 3. In 18 cases there was deaf-mutism in the family, but several families supplied more than one child to the institution. Ten children showed evidence of past middle-ear suppuration, 16 had a little hearing. In 23 the vestibular apparatus was normal, in 17 it was subnormal. Fifty-eight of the children were cases of acquired deafness. In 22 cases the deaf-mutism was due to the results of zymotic diseases other than epidemic cerebro-spinal fever. Of these 22, 17 had learned to speak before the onset of the deafness, but by the time they were sent to the school speech had practically disappeared. In 3 chronic middle-ear suppuration was still present; 9 had had mastoid operations, 2 had large dry perforations, 2 had retracted scars, and in only 4 was there anything like a normal drumhead. In 11 cases vestibular reactions were absent; in 8 others they were practically absent. Cerebro-spinal fever was responsible for more marked deafness than was any other condition, and it was associated with great loss of vestibular reactions. There were 17 of these cases. Congenital syphilis was present in 7; in some the Wassermann reaction failed to reveal the syphilis.

The PRESIDENT spoke highly of the value of the demonstration, and paid a tribute to Dr. Fraser for the beauty of the preparations.—Mr. A. CHEATLE asked whether Dr. Fraser had any views as to why islands of hearing occurred in these cases. With regard to the site of the malformation, it was held that the structures which were late in the evolution of the ear were more liable to malformation than those formed at an earlier epoch, and the cases now illustrated bore that out.—Dr. ALBERT A. GRAY (Glasgow) said he had found that the tensor tympani muscle had not undergone any degeneration in deaf-mutism. Very few deaf-mutes were absolutely deaf, and he suggested that the response occasionally to the loud sounds heard was sufficient to keep the tensor tympani healthy. He was not able to speak of the stapedius. And instead of the labyrinth in these cases being smaller in size than the normal, he had found it to be even larger than in the usual child.—Dr. DAN MCKENZIE expressed his satisfaction that this somewhat neglected region of aural investigation was being taken up. He thought it important to endeavour to differentiate between cases due to intra-uterine disease and those owning some hereditary defect. The precise nature of the latter was still questionable. It was interesting to note that in two of Dr. Fraser's cases there had been fracture of the cranial base. He discussed the probable mode of infection in cases of the condition having followed meningitis.—Mr. SYDNEY SCOTT congratulated the exhibitor and the Section on the beautiful sections shown by Dr. Fraser. One of the most interesting of the series was that in which in one ear there was a distended ductus cochlea, and in the other there was collpase of that structure, and he thought the following up of that subject might throw some light on the origin of the perilymph and endolymph.

Dr. FRASER, in his reply, said he believed that in congenital deaf-mutes the organ of Corti was badly formed, but not sufficiently so to preclude the hearing of very loud sounds; it was comparable to the perception of a bright light by a very defective eye. In the first case of which he showed slides, the part of the otic vesicle which normally formed the utricles and canals developed all right, but that which was going to form the saccule of the cochlea did not expand properly. There was no sign of abnormality in the vascular supply of the cochlea. He remarked on the French view that congenital deaf-mutism was not so much a question of the inner ear as of the hearing centres in the brain, and he intended to report later on the brains of these cases.

Sinusitis in Children.

Mr. F. J. CLEMINSON read a paper on this subject, based on a study of 85 cases. The sinus chiefly considered in this contribution was the maxillary antrum, but some of the cases showed ethmoiditis, and some frontal sinusitis infection also, with probably involvement of the sphenoid. The ages of the cases varied from 3 to 14 years. Among the symptoms complained of were running at the nose, nasal obstruction, constant cold, deafness, chronic cough, frontal or supra-orbital headache, mental dullness, and lethargy; very occasionally there was nose bleeding. Otorrhœa might be present in one or both ears. Diagnosis rested on the symptoms and signs, transillumination, radiography, and exploratory puncture. One case dated back to an attack of diphtheria three years before, and that raised the question of carriers during a long period. In 15 of the cases the infection was due to a single organism. Many cases of recent infection cleared up after a solitary puncture.

The paper was discussed by the PRESIDENT, Mr. SCOTT, Dr. E. WATSON-WILLIAMS (Bristol), Mr. H. D. BLASTOW, Mr. G. H. LAWSON WHALE, and Dr. J. S. FRASER, and Mr. CLEMINSON replied.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

TRYPANOSOMIASIS: NEW METHOD OF TREATMENT.

AT a meeting of this society, held on May 20th, Prof. W. J. R. SIMPSON presiding, a paper was read by Dr. CLAUDE H. MARSHALL, S.M.O., Uganda Protectorate, on this subject. He prefaced an account of the treatment, which had been originated by Dr. S. M. Vassallo, of the Uganda Medical Service, and himself, by reference to the causation of sleeping sickness and its dependence on the three factors—(1) the human host, (2) glossina tsetse-fly, and (3) the trypanosome. Any two of these were harmless in the absence of the third, therefore the disease might be dealt with either by exclusion of human beings from tsetse-fly areas, banishment of the fly by robbing it of shelter and food, or by the cure of infected persons. It was pointed out that application of the first of these measures involved surrender to the glossina and abandonment of vast tracts of country. Destruction of the fly's breeding ground and removal of its food-supply had met with only limited success. Efforts at cure of infected people had proved most discouraging, for, in spite of marked temporary benefit resulting from many drugs, no permanent cure could yet be relied on. Administration of a single dose of salvarsan, neosalvarsan, or atoxyl sufficed to sterilise the blood temporarily, but after about four months the disease recurred and was eventually fatal.

To explain this unhappy course of events two theories had been advanced—(1) that the trypanosome in a resistant form became atoxyl-fast; (2) that some of the parasites escaped the drug by seclusion in the central nervous system. The latter explanation he regarded as the correct one, and supported it by reference in detail to four cases, whose blood and gland juice proved to have been freed from parasites by intravenous injection of neo-kharsivan, but whose cerebro-spinal fluid had been found to contain trypanosomes as early after infection as three days and as late as 3½ months in each instance in two of the four cases. He suggested that the marked thickening of the cerebral meninges, found in post-mortem examinations on fatal cases of the disease, was due to the action of the trypanosome in the central nervous system in producing thickening and occlusion of the choroid plexus at an early stage of the disease, and thus preventing access of drugs from the circulation into the spinal fluid. In support of this view he quoted Prof. A. Keith as authority that infections in the basal cisterns of the brain reached the cervical glands, probably through the nerve sheaths, where some connexion existed between the cerebro-spinal and lymphatic systems. On these grounds Dr. Marshall regarded intravenous medication as useless, when once the central nervous system was invaded, as, whatever drug was employed, its effect would be confined to the general circulation. In 1918 he first attempted intrathecal treatment. He injected a patient with 0·6 gm. of neokharsivan intravenously, followed three days later by injection of 0·025 gm. of the same drug into the spinal canal. This proved a failure, for the man died on the following day. In a subsequent well-marked case of sleeping sickness, however, three hours after intravenous injection of neokharsivan, he withdrew two ounces of the patient's blood, kept it under sterile conditions for 20 hours, and then injected 20 minims of the resulting serum into the spinal canal, the same amount of spinal fluid having been previously drawn off. No further treatment was given. Examinations of the blood at intervals of three months had failed to show any parasites, and when last seen in December, 1920—i.e., 27 months after the original injection of serum—the patient was quite well. Up to the end of 1919, 13 other cases had been similarly treated, and the results had been published in the *British Medical Journal* of May 22nd, 1920. Dr. Vassallo, who had relieved him in February, 1920, had kept these cases under observation, and had dealt with a number of others on the same lines in the past year.

The results of 30 cases so treated by intravenous injection of neokharsivan, followed by intrathecal injection of serum, were recorded in a table. This showed that after intervals varying from 27 to 6½ months from the date of treatment to December, 1920, 23 cases, or 76·6 per cent., were quite well, the blood and cerebro-spinal fluid had proved negative on examination, and the enlarged glands had disappeared. In 4 cases no records of after-history existed, and 2 cases, or 6·6 per cent., in a very advanced stage at the time of treatment had died. A further series of 23 cases treated less than six months previously had been re-examined with negative results and appeared quite well. Dr. Marshall discussed the possible action of salvarsanised serum injected into the spinal canal, and did not consider the beneficial effects were attributable purely to its antiparasitic properties. It was suggested that normally the formation of some trypanolytic antibody, in response to a blood invasion by the parasite, effected a natural cure only in so far as the circulation was concerned. The cerebro-spinal fluid containing no antibodies and being cut off from the blood by pathological changes, already put forward, it followed that a natural cure could not include the central nervous system. He maintained, however, that blood serum containing trypanolysin, when injected into the spinal canal, was capable of killing the parasite there either by direct action, or, in the opinion of Dr. Abadie of Paris, by stimulating the formation of complement. Dr. Marshall related, in support of the trypanolysin theory, that in several patients, who had received no intravenous treatment at all, a quantity of blood had been drawn off from a vein and allowed to stand for three days. The serum had then been injected into the spinal canal, on the supposition that the exposure would have killed off any existing trypanosomes in the blood, and that the trypanolysins contained in the serum would dispose of the infection in the cerebro-spinal fluid, simultaneously with the destruction of the parasites in the blood stream by their own antibodies. The first case so treated had shown good results for six months up to December, 1920, when no trypanosomes were found in the blood or spinal fluid, and enlarged glands in the neck had disappeared.

He stated that Dr. Vassallo, following up this of treatment, was now trying the effect of the intrathecal injection of serum from a previously treated case into a patient with sleeping sickness, but it was too early yet to give an opinion as to the result. Great interest attached to the case of their only European patient, who was present at the meeting, and whose history Dr. Marshall described in detail. Attacks of what was thought to be malaria began on July 30th, 1920, and on August 24th abundant trypanosomes were found in the blood. When seen a month later the man had lost 2 st. in weight, and suffered from lassitude, malaise, loss of appetite, attacks of vomiting, headache, and pains in the back and limbs. Blood examination showed two or three trypanosomes per field. He was treated by intravenous injection of 0·9 gm. of neokharsivan, and half an hour later blood was withdrawn from a vein—12 c.cm. of the resulting serum were injected into the spinal canal. A severe reaction, lasting several days, was followed by uninterrupted recovery, the loss of all symptoms, and complete regain of weight. Subsequently, in November, 1920, although the blood yielded a negative examination microscopically, one of two rats which had been inoculated with the patient's blood showed trypanosomes four weeks later, while the other proved negative. At the end of 1920 examination of the patient by Prof. J. W. H. Eyre revealed one degenerate trypanosome in eight slides, but sub-inoculations of his blood into guinea-pigs gave negative results. Various possibilities were discussed to explain the course of the case, and it was regarded as probable that the presence of degenerating trypanosomes was but a feature of the normal process of cure by the new method. Subsequent examinations of this patient's blood and cerebro-spinal fluid, which were also inoculated into rats and mice in January and April, 1921, and as recently as May 2nd, had all yielded negative results, and in view also of his present robust appearance, they felt justified in presuming the case cured. It was proposed in future to treat advanced cases of sleeping sickness by injecting serum into the lateral ventricles as well as into the spinal canal, on account of possible occlusion of the foramen of Magendie by thickened membrane preventing intrathecal injections from reaching the cerebral cavity.

In conclusion, Dr. Marshall held that of the two distinct foci of infection, the central nervous system was the more important, and could be dealt with by a single dose of serum. He regarded the results of such serum treatment in over 50 cases as better than any hitherto obtained by injections of salvarsan, atoxyl, antimony, or other drug preparations, and suggested that a trypanolysin was responsible for the cure. In this belief it appeared reasonable to make use of animal serum for treatment, and to hope that in man prophylaxis and immunisation against trypanosome infection might be so attained and early diagnosis effected by complement-fixation tests—problems which Dr. Vassallo was investigating. With reference to the possible application of a similar scheme of treatment in order to check trypanosomiasis in animals, Dr. Marshall urged the coöperation of veterinary medical science in forwarding so important a line of research.

Discussion.

In opening the discussion on Dr. Marshall's paper the PRESIDENT commented particularly on the very healthy appearance of the patient exhibited, which lent justification to the belief in his cure. He referred to Prof. Warrington Yorke's paper read at a previous meeting on trypanosomiasis, which had given rise to a lively discussion on the experimental suggestions made as to the advisability of prophylactic game destruction, and as to the sum of £50,000 required for the investigation of the problems of sleeping sickness. Then both the medical and veterinary aspects had been discussed; now the question from its purely medical and therapeutic standpoints had been brought to notice, and the light thrown on the subject by Drs. Marshall and Vassallo offered a brilliant means of treating trypanosome infection. It was impossible to estimate, in coping with so great a scourge of tropical Africa, what such a solution would mean to Africa. In his opinion the paper just read was one of the most valuable yet brought before the society, and promised to deal effectively with the human form of trypanosomiasis. The group of 30 cases treated by serum showed 22, or 73 per cent., to be still alive and well; of 13 who had been treated a year or more ago, 9, or 69 per cent., were now living and in good health. He regarded these high percentages of recoveries as a great and remarkable achievement compared with the few recoveries under other methods of treatment. There remained to be seen whether the same good results would be obtained with the Rhodesian type of infection. The line of treatment by this serum-therapy rested on a thoroughly scientific basis; by allowing the patient's blood to stand, the trypanosomes contained in it were killed after yielding up their intracellular enzymes to the serum, which was used for intrathecal and intraventricular injections and obtained direct access to the most important focus of disease, the central nervous system. Prof. W. D. Halliburton in his presidential address in October, 1916, before the Physiological Society, had shown that in normal individuals injection into the cerebro-spinal canal enabled substances to reach the general circulation, whereas injections into the blood failed to gain the cerebro-spinal fluid. This fact would account for the failure of drugs, injected intravenously, to cure trypanosome infection, and justified the intrathecal method of administration of a serum, whose action was comparable to the effect produced in other diseases by the use of vaccines and sera containing specific intracellular products or bacteriolytic enzymes or antitoxins. Professor Simpson referred to the auto-serumtherapy of Dr. Senn, of Bombay, as providing a similar line of treatment. He had been impressed by the method advocated, which called for opportunity of trial on a large scale and appealed to veterinary coöperation and the wealth of a Rockefeller in order to place so important a discovery on a sound footing.

Prof. W. D. HALLIBURTON, speaking for himself, said that for many years he had been interested in cerebro-spinal fluid and the problem of its secretion and functions. He took exception to scientific workers remaining in the clouds and avoiding propositions of practical importance, and though admitting of qualification, quoted Prof. Karl Pearson's dictum that science, in its application to mankind, was the only form of science of value, whereas science for science sake was of no value. He congratulated Dr. Marshall and his colleague for their striking discovery, one which could be regarded as ranking in importance with that of Dr. Christopherson in the treatment of bilharzia by antimony tartrate.

The cerebro-spinal fluid was a secretion, not a leakage fluid like lymph. He drew comparison with the structure of the salivary gland composed of groups of cells arranged in acini and bordering a lumen through which the saliva passed to the mouth—the blood capillaries between and outside the acini leaked lymph, which was taken up by the cells and converted into saliva. In the case of the choroid plexus, or choroid gland as Prof. Mott called it, the blood-vessels lay inside and were covered by particular cells; the lymph which leaked from the blood was taken up by these choroidal cells and passed as cerebro-spinal fluid into the lateral ventricle and subarachnoid spaces. The cerebro-spinal fluid was of constant composition, an important point owing to the sensitiveness of the nerve cells which it bathed, and maintained a normal osmotic pressure beneficial to the nerve cells. The cells lining the choroid plexus afforded a barrier, preventing anything harmful—e.g., arsenic or antimony—from reaching the cerebro-spinal fluid, and so the nerve tissues, with the exception of volatile bodies—e.g., alcohol—the only substance known which could get through. By some back-door means spirochætes and trypanosomes did succeed in gaining admission to the cerebro-spinal fluid, where the only drug fatal to them was also fatal to the nerve tissues of the host, hence intrathecal injections of arsenic or antimony preparations could not be applied with safety. The fluid found means of exit through the arachnoid villi projecting into the sinuses—the sites of leakage of excessive cerebro-spinal fluid, which, therefore, passed into the blood stream and not into the lymph. He regarded Dr. Marshall's view that the trypanosome, by having obtained access to the central nervous system, was protected from the action of drugs in the circulation as the correct explanation of the failure hitherto attending efforts at treatment of sleeping sickness—that protection was afforded in part by the normal function of the choroidal cells, in part by occlusion, the result of trypanosome infection. The cells still opposed their barrier to abnormal substances, but allowed material of normal composition to pass through.

Dr. P. H. MANSON-BAHR described two Europea cases of infection by *Trypanosoma gambiense* whic he had under observation at the London School of Tropical Medicine. One was infected five years ago in the Congo district—there was no doubt as to the nature of the disease, but only once in five years had trypanosomes been found in the blood—and never in the cerebro-spinal fluid. It was now a typical case of sleeping sickness with symptoms of pachymeningitis. He asked whether in this case the disease was caused by trypanosome invasion of the central nervous system. In the second case Dr. Marshall's serum treatment had been tried, in addition to salvarsan and neokharsivan, with no effect on the regular appearance of the trypanosomes in the blood, which exhibited a large infection, amounting to a count of 16 trypanosomes to every 200 leucocytes. He asked in what way the treatment applied had gone wrong and urged the importance of treatment on a scientific basis. Natural immunity to trypanosomiasis was to be considered, comparable with that to malaria. An explanation was needed as to why some cases in which trypanosome infection was not a self-limited disease recovered by natural immunity and others resisted every form of treatment. Though not convinced as to the permanence of cure in his cases, he warmly welcomed Dr. Marshall's paper as a valuable contribution to the treatment of the disease. The recital of his own cases were a sad experience of treatment defied for over two years.

Dr. G. C. LOW thought that 21 years' experience, dating back to the Uganda epidemic, had given him a claim to know something of the treatment of sleeping sickness. He was sceptical as to the reliability of the cures which Dr. Marshall had claimed, but which time alone could guarantee. The enthusiasm attending the first use of one dose of salvarsan as the certain remedy for syphilis, when now we knew that even repeated doses, combined with mercurial inunction, did not effect a sure cure, did not incline him readily to accept Dr. Marshall's serum treatment of sleeping sickness as unquestionable. That some strains of certain parasites were extremely resistant to treatment by drugs had been proved in the case of malaria and leishmaniasis; and it was so also with trypanosomiasis, as in Dr. Manson-Bahr's cases. Out of all the Europeans who had come to England for treatment suffering from infection by *T. rhodesiense*, only one was alive, and another had lived for two years and seven months. He suggested that there were other hiding-places for the trypanosome than in the brain, and that the small-celled infiltration found in the heart muscle and other parts might be due to toxins poured out by parasites in such hidden foci of infection. He referred to latent cases of trypanosomiasis dying after four or five years' apparent freedom from the disease, and stated that no case could be regarded as cured in less than three years at earliest. It was impossible, therefore, to regard Dr. Marshall's cases as cured after only one year. He denied that a serum-therapy was essentially the method of cure, quoting cases which in Uganda as far back as 1902 had been cured by doses of liquor arsenicalis given by the mouth, by atoxyl, and others by antimony injections. Native cases of chronic infection showed the necessity for care in claiming cures. No untreated case among Europeans had recovered, although natives might survive for a considerable time. He hesitated to express an opinion in the presence of the patient attending the meeting, but candidly he did not regard his cure as certain and beyond doubt. He believed that it was premature to regard Dr. Marshall's method of treatment by one injection of serum as a so-called cure. The macroscopical evidence of infection of the central nervous system provided by pachymeningitis was not to be considered as the sole proof of cerebral invasion by the trypanosome, for it was by no means uncommon to find such evidence only after microscopical examination of the meninges. He found it difficult to understand trypanolytic action of the serum suggested by Dr. Marshall, and why the serum injected intravenously failed, but when given intrathecally succeeded in killing the trypanosomes in the cerebro-spinal fluid.

Lieut.-Colonel R. H. **Elliot** pleaded for full opportunity to be given to the trial of Dr. Marshall's new line of treatment, and suggested a movement appealing to the Colonial Office to take up the matter with a view to thorough investigation.

Sir **Hugh Clifford**, Governor of the United Provinces of Nigeria, in the course of his remarks, drew attention to the huge area covered by Nigeria, 535,000 square miles in extent, occupied by 17 million inhabitants, with only one political officer for every 64,000 population. He described the importance to be attached to the provision of a sound method of treatment as inestimable in dealing with sleeping sickness, a disease so crippling to the commercial prosperity of our African colonies. He drew a vivid picture of the insect-ridden condition which from time immemorial had dominated and moulded the character of inhabitants of the tropics, and so seriously influenced trade and productivity in tropical Africa. The tropical side of medicine was one which called for careful study by all those coming to live in the tropics, and should be encouraged in every possible way. Colonel Elliot's appeal touched him very intimately, and he would personally urge the Colonial Secretary to provide opportunity for Dr. Marshall's important discovery to be thoroughly tried and investigated.

Dr. E. T. **Jensen** referred to the financial assistance alluded to by Colonel Elliot as a substantial sum likely to be forthcoming to advance the means of treatment set on foot by Dr. Marshall's valuable work. He brought forward as a formal motion that every facility should be given to Dr. Marshall's work being carried further with a view to its being thoroughly tested in the treatment of sleeping sickness, and that representation to that effect should be submitted to the Colonial Office by the society.—This proposal was seconded by Lieut.-Colonel **Elliot**, and when put to the meeting was unanimously carried.

Dr. W. T. **Prout** hoped the new line of treatment would meet with every encouragement and trial. He laid stress on the point that Dr. Marshall had made no claim of a complete and final cure in the case of the patient present at the meeting, who certainly looked in the best of health. His results so far had been most promising, and he would avail himself of an early opportunity of representing the subject to the Colonial Office.

Dr. C. F. **Harford** avoided the technical aspect of the question of treatment, for it was 31 years since he had been in touch with sleeping sickness. He suggested that a difference existed between the cases treated in the country of origin and those treated here, which might account for points apparently at variance. In infected countries the greater opportunities, which were offered than in this country, of obtaining light on the problems of the disease might be one cause of difference in the results of observation. He much hoped the Colonial Office ould take up the matter, which on account of its great practical interest and importance should be probed to the bottom.

Dr. **Marshall** in his reply expressed his gratitude to the society for the reception given to his paper, particularly to Prof. Halliburton for his account of the choroid plexus, and to his Excellency Sir Hugh Clifford for his very kind remarks. Dr. Manson-Bahr and Dr. Low had made comparison between the uncertainty of treatment in sleeping sickness and that of malaria and syphilis. Because in some cases quinine and salvarsan respectively had no effect on either of the two latter diseases, was no reason why they should not be tried in ordinary routine cases; the same argument surely applied to trypanosomiasis and its remedy. The European had a higher resistance to trypanosome infection than the native. If cases in natives had gone on for two years without treatment and remained well, it was a sign they had improved even if they had not been cured.

A cordial vote of thanks to Dr. Marshall for his paper was unanimously carried.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THE ANNUAL CONGRESS.

(*Concluded from p. 1136.*)

Mr. E. **Treacher Collins** delivered the Bowman Lecture, taking as his subject Changes in the Visual Organs, Correlated with the Adoption of Arboreal Life and the Assumption of the Erect Posture.

Treatment of Manifest Concomitant Strabismus.

A discussion on this subject was held on Friday morning. It was opened by Mr. **Claude Worth**. He said the matters to be considered in the treatment of convergent squint were: (1) prevention or cure of amblyopia exanopsia; (2) correction of refractive error; (3) fusion training; (4) operation. If a constant unilateral squint had lasted a considerable proportion of the child's life, in the absence of efficient treatment, the deviating eye would be found to be more or less blind; and it was the prevalent view that the amblyopia was usually the result of disuse. The younger the child the more rapid was the loss of sight; one who began to squint constantly at one year of age might lose central fixation in three to four months. The child must be forced to use the deviating eye; this was far more important than all the rest of the treatment of squint. In a case of recent squint, in order to prevent amblyopia or to cure low degrees of it, the fixing eye should be kept under atropine until it became the deviating eye. The child should then be seen again after the effect of the atropine had passed off. After this the deviation must be kept alternating, one or other eye being atropised occasionally, if necessary. If central fixation in the deviating eye was absent or unsteady, the atropine treatment was not sufficient: then the fixing eye should be continuously occluded. With regard to the correction of refractive error, he said no child was too young to wear glasses if they were required. In regard to fusion training, certain principles must apply to all methods. The child must be young, preferably under 6 years of age, and the sight of the deviating eye must be good. The most difficult step was to overcome the suppression. Most surgeons were now agreed that the essential cause of squint was a defect of the fusion sense. The object of fusion training was not to correct deviation—except in small degrees—but to enable the patient to see binocularly when the visual axes shall have been restored to approximately their normal relative directions. Discussing the question of operation, he said that if measurements showed that the angle of deviation was not decreasing, operation became necessary. If there was no hope of binocular vision, it was not his custom to operate until the seventh or eighth year. He frequently, at an earlier date in his career, performed tenotomy of the internal rectus in combination with advancement of the external in high degrees of convergent squint; but he abandoned the practice in 1905, and had since relied on advancement alone. Except in very small deviations, both externi were advanced. There were, he said, practically unavoidable failures in squint operations; the *result attained* was a measure of the skill and experience of the surgeon.

Mr. A. J. **BALLANTYNE** dealt with the subject of concomitant convergent squint, based upon his own experience. The first step should be an estimation of the refraction, and the prescription of suitable glasses to be worn constantly. In many cases the wearing of these, with training if necessary, sufficed. With one exception, his cases were aged 7 years or under. The largest degree of squint corrected was 40°, in a patient 18 months old, whose squint had lasted two weeks. In most of his cases the angle was 15° or less. In a number the eye was already amblyopic. In most cases, he thought, the amblyopia was the result of the squint, hence there was all the more encouragement to attempt to restore vision in the squinting eye. He applied atropine more or less continuously to the sound eye. He was now inclined to operate at an earlier age than formerly. Advancement alone in many cases would bring about an approximately straight position of the eyes; he had never seen over-correction caused by advancement or muscle-folding, hence he would not hesitate to operate at any age. He preferred muscle-folding in the youngest children. He rarely did tenotomy of the internal rectus, and never as the sole means of correcting the squint. In children it was wise to do too little, rather than too much; and if tenotomy was performed, it should be as a last resort. Cases in young children often suggested the existence of a state of excitability and instability of the accommodation and convergence centres, and in these cases the operative treatment of the strabismus was apt to be very disappointing. Failure in these cases was not due to slipping of the stitches, but to looking for a remedy of a mechanical kind for what was really a functional error. His results from training of fusion had been disappointing. We were, apparently, born with a certain racially-acquired degree of binocular equilibrium, but the finer coördination of the eyes necessary for binocular vision required to be learned, like the act of walking, by each individual, and the most useful line of inquiry would be along the evolution of binocular vision in the young child.

Mr. E. E. **MADDOX** referred to the numerous cases of squint in which the child was unable to fix its attention. Attention had a great effect, especially on the fusion faculty, and the defect in many children was, not the absence of the fusion faculty, but the lack of a stimulus to action. To correct hypermetropia, some occupation on near objects should be provided. Squinting children should be kept from reading early, and their parents should let them use large objects. Moreover, they should be encouraged to look upwards, as that produced a lessened tendency to convergence. He considered that the amblyoscope was very valuable in diagnosis.

Mr. T. **HARRISON BUTLER** said he could recall only one case in which he had *had* success with the fusion test; and in that, the case of a boy, he relapsed in a year. Fusion training must only be done in children under 6 years of age, but these were very difficult to educate in such a scientific procedure. He had not met with a patient who came and said he wanted binocular vision. Most operations for squint were asked for on cosmetic grounds. Eight he regarded as the most suitable age for operation, and he did not operate when the squint was no more than 25°.

Mr. M. S. **MAYOU** said that if a patient had good vision in both eyes and some attempt at fusion, he operated as early as possible, provided the patient had worn glasses a year without improvement. In convergent strabismus up to 15° he did tenotomy of the internal rectus; but in young children 20° could often be corrected by it. When the degree of convergent squint was from 15° to 45° he did an advancement—i.e., tenectomy associated with tenotomy. He preferred a shortening of the tendon and using the stump of the muscle attached to the globe for holding the sutures.

Mr. N. **BISHOP HARMAN** said the determining factors in squint could be grouped under three heads: (1) defects of the eyes, (2) defects of the muscles; (3) toxic influences. Among 368 infants in a higher-grade school, only 8 had emmetropic eyes. The others had errors of refraction, mainly hypermetropia, and in 126 the errors were considerable. Toxic causes did not claim a high place. The chief cause was defective muscle-balance, but it was not sufficiently recognised, and had not its due place in schemes of treatment. He referred to the recent establishment, in the Belgrave Hospital, of an operative clinic for squint. The method employed there was shortening of one muscle by sub-conjunctival reefing, with lengthening of the antagonist by tenoplasty.

Mr. A. L. **WHITEHEAD** (Leeds) said his experience was that squint was much more prevalent in hospital than in private practice. He attached great importance to the full correction of the squinting eye, even though it were amblyopic; and the results on the squint had been marked. The treatment should be carried on during from six to 12 months. It must not be forgotten that many cases showed a tendency to spontaneous cure. He liked tenectomy with tenotomy when operating, as Mr. Mayou did. He had never over-corrected when doing this.

Mr. **BROOKSBANK JAMES** did not regard the amblyoscope as of much use in the matter of training, but it was useful for detecting the presence or absence of the fusion faculty. He did not think squints could be wholly corrected by the reefing operation. He corrected refraction in children of the youngest age, but no adequate training could be done in a child under 4 or 5 years old. In operating, he preferred to do a central tenotomy, then wait, afterwards doing an advancement. He never did both at the same time.

Mr. **INMAN** thought none of the suggested explanations as to the cause of squint were adequate. Often the owner of the squinting eye had deliberately taken on a squint. A child worked its fusion centre, and then, at 3 or 4 years of age, a squint occurred. It had no reference to near work; and at 6 or 7 years of age it had become well developed, and its possessor was an object of sympathy. He said he had found that an amazing proportion of squinters were left-handed persons, yet among the general population the left-handed persons were from 2 to 4 per cent. Some members of neurotic families were left-handed, some had a stammer, some had a squint. A child practically never developed a divergent squint, the reason being that the convergent squint was the easier. He suggested the close watching of cases by members, and the subsequent comparison of experiences.

Mr. R. R. **CRUISE** showed a new form of amblyoscope which he had designed, in which ordinary stereoscopic pictures could be used. Those who used it could fuse at their angle and enlarge the amplitude of their fusion. In regard to operation, for many years he had not hesitated to tenotomise. The bogy of divergence, he considered, was greatly exaggerated, especially if one did an advancement first, then tenotomised, dissecting up the conjunctiva to the caruncle. He described the method in detail.

Mr. E. H. **STACK**, discussing the operations for squint, said he seldom did tenotomy of the external rectus. He advocated a routine examination of the eyes of children before 4 years of age. Proper prisms or spectacles in these early years would probably do very much to save those which could be corrected.

Mr. **WORTH** and Mr. **BALLANTYNE** replied.

Clinical Meeting.

On Friday afternoon members attended a demonstration of clinical cases and apparatus at St.

Thomas's Hospital. In the evening, at No. 1. Wimpole-street, further papers were read and discussed.

The Iris-Prolapse Operation for Glaucoma.

Lieutenant-Colonel H. HERBERT read a communication entitled, "A Justification of the Wide Iris-prolapse Operation for Glaucoma." He said the value of the treatment must be determined mainly by the two vital questions: the completeness and permanency of the relief of tension provided, and the safety in the matter of late infection. In a few of the severer chronic glaucomas full relief from abnormal tension was obtained by this method much less quickly and less easily than by some other iris-inclusion operations. But it was in the permanency of relief of tension that iris-inclusion operations in general stood out pre-eminently. This could not be said of many iris-free leaking cicatrices. In the last two years he had come across 13 instances of a late return of tension after iris-free operations. With regard to safety in the matter of late infection, subconjunctival prolapses could be divided into four grades, and these he described. The object of the paper was to remove some of the prejudice with which the operation was viewed.—Several members discussed the paper.

The Rational Treatment of Glaucoma.

Mr. T. HARRISON BUTLER read a paper on this subject. He said there was still considerable difference of opinion as to the significance of the changes discovered in the glaucomatous eye. Examination of the fields of vision both as to the periphery and the centre was of extreme importance. He now rarely operated upon patients for glaucoma in the acute stage; under suitable treatment most cases *quieted down*, and then the operation was much safer. His practice now was to do the so-called "trap-door iridectomy"—i.e., trephining with a 1·5 mm. instrument and leaving the disc with a hinge. He proceeded to discuss the *non-operative* treatment of glaucoma, remarking that his own experience overwhelmingly favoured early operation —i.e., as soon as loss of function was realised.

Mr. C. GOULDEN read a paper by himself and Mr. M. H. WHITING on Implantation Cyst of the Sclera following an Operation for Squint, in which they discussed the general subject and gave clinical and pathological particulars of cases.

Sir WILLIAM LISTER read papers on (1) Some Intra-ocular Epithelial Cysts: (2) Punctate Deposits in the Retina.

On Saturday morning there were further papers. Mr. P. G. DOYNE read one on observations with the scotometer, Sir ARNOLD LAWSON on a case of orbital tumour, which turned out to be a neuroma of the nasal branch of the fifth nerve; MR. HAROLD GRIMSDALE on the Mechanism of the Stability of the Eye.

Extract of Cataract by Suction.

Mr. A. W. ORMOND communicated a note on a Method of Extracting the Crystalline Lens in its Capsule by "Suction." The method was introduced to obviate the movement of the lens when incising the anterior surface of the lens with a sharp hook. He showed and demonstrated the apparatus used, which was on the same principle as the Bunsen-Sprengel pump.

Dr. GEORGE MACKAY (Edinburgh) sent a communication explaining a mechanical contrivance for trephining, and Mr. Traquair demonstrated it. It is actuated by clockwork, and can be employed in using Newton's colour top as devised by Mr. Percival.

During the Congress an extensive optical exhibit, by various well-known firms, was held in the building, and the optophone was demonstrated.

The members dined together on Thursday evening, the attendance at all the sittings was well ntained.

Reviews and Notices of Books.

BLOCK ANESTHESIA AND ALLIED SUBJECTS.

With Special Chapters on the Maxillary Sinus, the Tonsils, and Neuralgias of the Nervus Trigeminus. By ARTHUR E. SMITH, D.D.S., M.D. London: Henry Kimpton. 1921. Pp. 895. 90s.

THIS large volume is intended for oral surgeons, dentists, laryngologists, rhinologists, otologists, and students, but it is to practitioners and students of dentistry that it will make its chief appeal as a text-book. The book opens with a history of general and local anæsthesia and closes with a consideration of post-operative complications and their treatment. The chapters of most importance are those which describe in detail the technique of local anæsthesia of the branches of the fifth cranial nerve; the methods of nerve-blocking each branch are discussed systematically and very fully under such headings as Topography of Anatomy, Needle Employed, Technic of Injecting Structures Anæsthetised, &c., with the object of enabling the practitioner to find at once full details of the particular part on which he is working. The numerous illustrations of these sections are for the most part of considerable practical value, and a great deal of labour has been expended on their preparation. There is a detailed and accurate account of the anatomy of the nerves of the face, mouth, and neighbouring regions. with excellent photographs of dissections and diagrams which show every branch from several aspects.

The rest of the book gives a rather lengthy description of a number of matters which are nearly or remotely related to block anæsthesia, including such subjects as a classification of the nervous system, intravenous, intra-arterial, and spinal methods of anæsthesia, and the chemistry of local anæsthetic drugs. Dr. Smith's attempt to leave nothing unsaid is shown by the devotion of some 70 pages to a description of the various drugs that have been used for local anæsthesia, and by the complicated armamentarium of syringes and other instruments that are described and illustrated. The wisdom of giving so much space to allied subjects is open to question, and it may be thought that such detailed accounts as that of the surgery of the maxillary sinus are rather out of place; on the other hand, the treatment of trigeminal neuralgia seems well within the province of the book, and the technique of alcoholic injection has received a full description which should prove of real value to surgeons and neurologists. There are photographs and diagrams excellently reproduced; those which illustrate the anatomy and technique of block anæsthesia are of definite value, but the numerous pictures of simple instruments might well have been omitted.

The statement in the "Foreword" that this is not a book for the timid or for cowards is very true, for the mass of detail makes it rather difficult to read. It is the repetitions, illustrations, and minute descriptions of matters, some of which have little bearing on the main theme, that have made the volume bulky and expensive, and to some extent must counteract the real value of its more practical portions; the latter, however, should prove of great use to the oral surgeon, and the book is likely to be employed as a work of reference by those interested in the many branches of surgery on which it touches.

MANUEL DE COPROLOGIE CLINIQUE.

By R. GOIFFON. With a preface by Dr. J. CH. ROUX. Paris: Masson et Cie. 1921. With 36 figures and 2 coloured plates. Pp. 232. Fr.12.

EXAMINATION of the fæces is probably more neglected than any other aid to exact diagnosis, partly no doubt owing to the fact that the information to be gained from a systematic analysis is not yet fully appreciated. Nothnagel, some 30 years ago, laid the foundations of a scheme of fæcal analysis, but it is only within the last 10 or 15 years that our knowledge of the physiology of the gastro-intestinal tract has advanced far enough to permit of an intelligent interpretation of the fæcal abnormalities met with in disease. It is now realised that the fæces are not merely food residues which have escaped digestion, but are a complex product derived from the intestinal secretions and bacteria, mixed with derivatives of the food arising from the action of the digestive ferments, and further modified by the activities of micro-organisms and the intensity of the peristaltic movements of the bowel. The analysis of such a mixture presents many difficulties, and the interpretation of the results obtained calls for very considerable skill and experience. The author of the volume under review has had charge of a department dealing with such investigations for many years and is therefore peculiarly fitted to discuss the problem. He does not attempt an exhaustive survey, but confines his attention chiefly to the methods he has found of practical value.

The book is arranged in four parts, of which the first deals with the physiology of the alimentary tract, and although brief, this section is adequate for the purpose in view. In the second part the technique of fæcal analysis is dealt with, and this constitutes the major portion of the work, occupying 130 out of the total of 230 pages. After discussing various test-diets and their respective spheres of usefulness, the author considers the macroscopic and microscopic characters of normal and pathological stools. He then passes on to the chemical reactions, dealing first with the normal and then with the abnormal constituents, including blood. For the detection of the latter he advocates the Kastle-Meyer phenolphthalein reagent as a preliminary test, but he advises that a positive result should always be controlled by Weber's guaiacum test, which he considers shows only a quantity of blood of pathological significance. The quantitative estimations for clinical purposes he limits to determinations of the dry weight, the volatile fatty acids, the total nitrogen, the ammonia, the fats, and the bile pigments, particular stress being laid upon the measurement of volatile fatty acids and ammonia as an index of the type of intestinal flora. The commoner intestinal parasites are considered and adequately illustrated in this section, which also includes an account of the digestive ferments met with in the fæces. The bacteria of the stools are dealt with more from a general than a special point of view, but directions are given for the detection of various pathogenic organisms. The interpretation and diagnostic significance of the results obtained are discussed in the third portion of the book, which is divided into twelve sections dealing with the various secretory, bacterial, and motor affections of the alimentary tract.

The final ten pages are devoted to a condensed account of treatment. This is the least satisfactory portion of a book which, as an introduction to clinical coprology, is a work of distinct merit.

DIAGNOSIS OF PROTOZOA AND WORMS PARASITIC IN MAN.

By ROBERT W. HEGNER and WILLIAM W. CORT.
From the Department of Medical Zoology,
School of Hygiene and Public Health, the
Johns Hopkins University. Baltimore: The
Johns Hopkins Press. 1921. Pp. 72.

THIS bulletin has been prepared for the use of physicians and public health workers who are called upon to diagnose diseases caused by protozoa and worms. It has been compiled from original articles in periodicals and from standard text-books, and the aim of the authors has been to include only those parasites which are of practical importance to the medical man. It is clearly written and well illustrated, and should prove of value to those for whom it is intended. Adequate references are given to the literature of the subject.

THE POLARISED MICROSCOPE.

Die Ultra- und Polarisations-Mikroskopische Erforschung des Lebenden Auges und ihre Ergebnisse.
Von Dr. LEONHARD KOEPPE. Leipzig: E. Bircher.
1921. Pp. 270. Fr.20 (Swiss).

IT is some ten years since the application of a specially designed microscope, used as an ophthalmoscope of high power, to the examination of the tissues of the living eye was demonstrated by Allvar Gullstrand, at Heidelberg, and taken up in Germany. Among other ophthalmologists Dr. Leonhard Koeppe has specialised in the use of the instrument and has become a large contributor to the literature which has grown up around it. This literature threatens to become over-specialised, and of this tendency the present book affords a striking illustration. It is devoted, as its title suggests, to an extremely small subject—that is to say, the use of this very special instrument with particular appliances for producing dark field and utilising polarised light. That both these expedients are useful may well be believed, but a perusal of Dr. Koeppe's book in itself is not convincing. He speaks of having worked at this phase of the subject for two years past, but he brings forward no results, and, indeed, the most striking feature of the book is the complete absence of clinical demonstrations. It is written much in the style of an elaborate manufacturer's catalogue, containing a detailed and well-written description of the instrument and a full technical account of the method of its use. This is serviceable matter, although of less interest to the general medical reader than would have been an account of results obtained by its means.

The bulk of the book is increased by much irrelevant matter. Thus, a very elaborate account is given, by way of introduction to the theory of the instrument, of the researches of Fraunhofer and Fresnel upon the phenomena of diffraction exhibited by extended wave fronts. The matter so introduced is of small value where it stands; it is to be found in all elementary works on physical optics and for the optics of the microscope it has no meaning whatever. Objects viewed by means of a microscope are always viewed in the focus of the instrument, where the image forming wave fronts are all contracted to mere points and the Fraunhofer and Fresnel phenomena disappear wholly. Many years ago the late Professor Abbé, head of the Zeiss firm at Jena, propounded a theory of image formation in the microscope in forgetfulness of this distinction, and on the strength of it ventured a prediction that no optical instrument would ever yield a resolved image of an object having a diameter less than half a wave-length of the light by which it was seen. Some years afterwards details transcending this limit were photographed by means of a lens constructed by the Zeiss firm, and, still later, Lord Rayleigh showed that an ordinary telescope would resolve a grating having an angular magnitude amounting to less than a fourth of Professor Abbé's impassable limit. Of these disturbing facts the author of this work seems to be unaware, since he largely fills his pages with reiterated expositions of this exploded Abbé theory. The book, therefore, is one that needs to be read with critical discrimination, but so read it will repay the attention of readers who are interested to learn what is being done in this branch of ophthalmology.

CLINICAL BACTERIOLOGY AND HÆMATOLOGY.

For Practitioners. Sixth edition. By W. D'ESTE
EMERY, M.D., B.Sc. Lond. London: H. K.
Lewis and Co., Ltd. 1921. Pp. 310. 15s.

THE sixth edition of Dr. d'Este Emery's valuable handbook differs from the last one in only a few minor verbal alterations. It was written primarily for the general practitioner, and the author has wisely refrained from over-elaboration. All the recognised procedures for the laboratory diagnosis of disease are described, but controversial matter is rigidly excluded; and though the busy practitioner may not be in a position to carry out the actual investigations for himself, he should be able, with this book in his library, to interpret laboratory reports and to view them in their proper perspective. At the same time the scope of the work is sufficiently wide to make it of real help to those specialising in clinical pathology, and there must be few clinical laboratories in which it is not now in constant use.

THE ENDOCRINES.

By SAMUEL WYLLIS BANDLER, A.B., M.D., F.A.C.S., Professor of Gynæcology, New York Post-Graduate Medical School and Hospital. London and Philadelphia: W. B. Saunders Company. 1921. Pp. 486. 35*s*.

Professor Bandler is an enthusiast. To him the endocrine glands have an importance far beyond that up to now assigned to them, and the development and functional activity of the various structures of the body, the psychoses and neuroses, normal and abnormal, are all under their dominance. In fact, the effects of heredity and environment, racial and sexual differences, and temperamental divergences, can be appreciated only by an understanding of endocrine activity and inter-relation. The early chapters of his book are thus devoted to a general discussion of the influence of heredity and environment on the child, and of the various influences by which the activities of the dominating endocrines may be modified. As a gynæcologist Professor Bandler is particularly interested in disorders affecting women, and he devotes a large part of his book to a discussion of the normal and abnormal female constitution. His theories are the product mainly of clinical observation and of his experience of endocrine therapy, but are also supported in many cases by operative proof.

This book will appeal primarily to the gynæcologist, but it also deserves a wider circle of readers. The chapter dealing with the endocrine factors involved in puberty and the climacteric is very sound. Professor Bandler shows how early recession of thymus activity determines early puberty, while its persistence delays the onset of puberty. The influence of diminished or increased secretion of the thyroid, anterior and posterior pituitary, suprarenals, and ovaries on the mental and physical activities is elaborately discussed. In regard to the suprarenals, Professor Bandler suggests that the medulla responds to stimuli by translating them into the emotion of fear, whilst the cortex converts them into the emotion of anger, and that the medulla predominates in the female, cortex in the male. Menstruation he likens to a miniature labour, in which the unfertilised ovum is expelled by the influence of the posterior pituitary, just as in normal labour the fœtus is so expelled. He explains the amenorrhœa of pregnancy as due to the production first by the trophoblast and later by the placenta of a secretion controlling the activities of the posterior pituitary and the ovaries. During labour, with the separation of the placenta, this control is assumed to be lost.

Professor Bandler holds decided views on the effect of the placental secretion in the disorders of pregnancy. In eclampsia he believes the post-pituitary to be over-stimulated by the placental secretion, and this, combined with deficiency of thyroid, he considers to be the basic factor in the toxæmias of pregnancy. In this connexion we may note that in this country administration of large doses of thyroid extract in threatening eclampsia is stated to have proved effective in the hands of many practitioners in preventing convulsions and hastening labour. Disorders of the climacteric, sterility, dysmenorrhœa, according to Professor Bandler, are all amenable to endocrine therapy; and his optimism extends even o the view that in a few years' time there will be little mental disease, cancer, diabetes, or renal sease, for, as they are all due to endocrine aberrations, they will be corrected in their earliest stages by the administration of appropriate glands. Chapters are devoted to the psychoses, phobias, and insanity. The views here, as elsewhere, are speculative. In regard to the therapeutic use of gland extracts the author has apparently little use for parathyroid in neutralising thyroid toxæmias, though many authorities consider it of value; nor does he mention pancreatic extract as an aid in controlling thyroid and suprarenal excess. Recent investigations on the effect of vitamine deficiency in producing failure of gland function is not discussed.

The book concludes with a chapter devoted to clinical cases, illustrating the author's methods of diagnosis and treatment.

JOURNALS.

IN the *Journal of the Royal Army Medical Corps* for May Colonel S. L. Cummins has a paper on tetanus as it affected the British Army during the war, between the dates of August, 1914, and December, 1918. During this period, he tells us, this terrible complication of wounds was controlled by prophylactic inoculation for the first time on record. The cases of tetanus arising in hospitals in England between August and November, 1914, were 163; thereafter antitetanic serum became available for every wounded man, and in a later period, also of four months, January to April, 1918, when fighting was again very heavy. At the later date the British force was ten times the size it had been in the first period, and the number of wounded was greater than the whole British Expeditionary Force that landed in France in August, 1914; yet hospitals in England showed only 90 cases of tetanus. From 7 divisions in 1914, 163 cases arose; with antitetanic serum available for all in 1918, from 70 divisions there arose only 90 cases. Further, in November and December, 1916, 13 cases arose in men suffering from trench-feet. In December, 1916, antitetanic inoculation was ordered for this condition as well as for wounds, and in 1917 only one case of trench-foot was followed by tetanus. Thirteen in two months before, one case in 12 months after prophylactic inoculation had become the rule. The initial immediate dose should be 750 units, or 1500 if wounds are specially severe. Three injections should be given weekly as a following routine, and another when further operative measures are to be undertaken. The case mortality in 1914, as in the old wars, was 80 per cent.; in 1918 it was reduced to 50 per cent. Inoculation delays the onset of tetanus, the delayed cases are less deadly, and, besides, we now hear of cases of merely local tetanus, a mild form of the disease unheard of in our earlier wars. The treatment of wounds by incision and the use of smooth-running motor ambulances also helped. A better prophylactic serum may be obtained in the future, as Captain W. J. Tulloch has been able to distinguish tetanus bacilli into four classes. The serum is not yet proved to be useful in treatment, though some laboratory experiments suggest it may be. An officer writing on the "Field Ambulances," asks that the A.D.M.S. of the division should live in the General's own mess, so that he should get always the earliest hints of movements, and again begs that the transport personnel shall be drawn, not from the R.A.S.C., but from the R.A.M.C. Another letter insists that the trained soldier shall get 30 minutes physical training daily. Without it he tends to become soft and fat by comparison with the hardness and fitness of the recruit.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The Cavendish Lecture will be delivered at the Kensington Town Hall by Dr. Addison, on Friday, June 17th, at 8.15 P.M., and will be followed by the annual conversazione. The subject of the lecture will be the Part of the State in the Prevention of Disease. Members requiring tickets for guests are requested to communicate as early as possible with the Hon. Secretary, Dr. D. G. Rice-Oxley, M.C., 22, Victoria-road, London, W.8.

THE LANCET.

LONDON: SATURDAY, JUNE 4, 1921.

The Dangerous Drugs Regulations.

THE regulations to be issued under the Dangerous Drugs Act, 1920, have been redrafted and are now themselves free from danger, for they will be administered with the willing coöperation of all parties concerned. Thirty-one professional bodies raised objections to one or other point in the original draft—the list begins with the British Medical Association and the Pharmaceutical Society of Great Britain, and ends with the Association of Unregistered Practitioners, Assistants and Animal Castrators—and the Committee appointed by the Home Secretary to consider and meet those objections have now presented the regulations in a form amended so as to cause no inconvenience to doctor, pharmacist, or public which, in the words of the report, "the seriousness of the evil they are designed to check does not justify." The drug habit does not now prevail in this country to the same extent as in the State of New York, but the Committee record their conviction that it does exist and that it might easily grow to serious proportions if not checked in time.

We print on p. 1205 the names of the Revision Committee and the text of the regulations as amended by them. The principal objections were three in number. First, the Pharmaceutical Society asked that the requirement of a prescription should be withdrawn altogether. To this the Revision Committee replied that the only legitimate use which the public can have for narcotic drugs is a medical one and in general the principle of requiring a doctor's prescription must stand. Certain familiar remedies, specified in a schedule, are, however, to be exempt from the operation of the regulations. Thus the employment of Dover's powder, of gall and opium ointment, or of the pill of mercury and chalk with opium, is admittedly unlikely to conduce to drug habit and will therefore not be subject to any new restriction. Cocaine having a more insidious effect, no relaxation is suggested, the Committee rather expressing regret that the Act itself gives no power to control the drug in dilute form. Secondly, it was urged that the loophole afforded by fraudulent copying removed "the alleged protection of what purports to be a medical prescription." To meet this source of evasion, the Committee would have all narcotic prescriptions written on special forms supplied to the doctor by the registrar of births and deaths or other official, in so far as the printed forms now supplied by tens of millions to panel practitioners do not meet the case. Thirdly, the Committee frankly recognised that an exact record of incomings and outgoings in the case of a dispensing doctor or chemist could not be required—it was not, in their view, even implied in the regulations as first drafted. The doctor's entries in his day-book and the corresponding entries in the pharmacist's poison-book or prescription-book should, they think, be accepted as giving the information required by the Act. The doctor who dispenses his own medicine will, however, be required—on the whole, not unreasonably—to keep a record similar to that already obligatory in the case of cocaine.

A number of minor concessions tend greatly to the smooth working of the Act without sacrifice of any useful principle. Personal administration by a doctor is not to be deemed to be supplying the drugs within the meaning of the regulations. The prescription, while it must contain the name and address of the person for whose use it is meant, need not state the doctor's qualifications or contain the words "Not to be repeated," and it may by special direction actually be repeated on not more than three occasions at intervals to be specified. To meet the needs of medical practice, no prescription for a human patient need be labelled by the dispenser with the amount of narcotic drug contained in it, although the same principle is not extended to veterinary practice, where it is hoped that some nauseous denaturant may be found to prevent the use of animal remedies by human beings. Hospitals and public institutions may be exempted by the Home Secretary from the operation of the regulations under conditions to be determined. The Committee may be warmly congratulated on the attainment of a high degree of unanimity among themselves and the various professional bodies with whom they negotiated. The one and only reservation appended as a rider to the report embodies the pharmacists' objection to dispensing by the prescribing doctor, an objection which the Committee were not prepared to take up at the present time, although "in strict equity" they held there was much to be said for completely separating the functions of prescribing and dispensing.

◆

Glands in the Neck.

THE treatment of tuberculosis of the cervical glands, in common with that of all other forms of surgical tubercle, has been the subject of profound changes of opinion during the last two or three decades. Sir ALFRED PEARCE GOULD, in his recent address at the Middlesex Hospital, describes how, when he was first taught surgery, the view of the best and wisest surgeons was that every surgical interference with tuberculous glands was to be avoided, or at any rate should be limited to the mere opening of large superficial abscesses. A few years later LISTER advocated earlier incision and antiseptic dressing of these tuberculous abscesses; then this method was shown by the Leeds school of surgery to fail because the abscess is usually secondary to a caseous focus under the deep fascia. Later, again, very complete excision was practised, and now, as Sir ALFRED PEARCE GOULD truly observes, "you see little or nothing of any of these operations, but the subjects of tuberculous glands of the neck, who a few years ago occupied a large share of the time of all surgeons to general or children's hospitals, are now sent to the throat departments of these same hospitals, and are submitted to enucleation of the tonsils and eradication of adenoids."

It appears from this and other collateral evidence that timely removal of the tonsils and adenoids in cases of cervical adenitis obviates in many cases the necessity of extensive dissecting operations. Miss E. C. LEWIS, who opened the discussion on tuberculous adenitis on May 10th before the London Association of the Medical Women's Federation, similarly urged the importance of clearing up any infective processes in the drainage area of the glands. At this discussion Dr. ESTHER CARLING cited the striking cases of two young men with masses of enlarged cervical glands which completely cleared up under an open-air régime made possible by their employment as sanatorium porters. Her experience at the Berks and Bucks Joint Sanatorium, that nearly all cases of glands there do well without surgical intervention, coincides with that of Sir Henry Gauvain, who summarised his results before the Medical Society of London on March 14th,[1] in the case of non-operative treatment of surgical tuberculosis. He has long deprecated any interference with tuberculous abscesses other than mere aspiration, when this becomes desirable on account of tension. Chronic enlargement of the lymphoid tissue of Waldeyer's ring is extremely common among children of school age in this country, about one-third of these children being affected; and of 170 cases of hypertrophied tonsils examined by Dr. Dan McKenzie, in only three cases could no enlarged glands be felt in the neck. A slight degree of cervical adenitis is therefore a very frequent occurrence, being secondary in a large proportion of cases to enlargement of the tonsils; and this enlargement is doubtless usually the result of infection. The tonsil is chiefly a lymphatic gland, and its drainage area includes the nasal passages and naso-pharynx, infection of these regions being the probable cause of its enlargement; and it is now generally agreed that enlarged tonsils are seldom found in children in the absence of adenoids, but that adenoids are often present without definite tonsillar hypertrophy.

By no means all enlarged cervical glands are tuberculous, many being cases of so-called simple inflammation, but the proportion is difficult to estimate; the majority of cases of great enlargement and of chronic suppuration are tuberculous, and it is probable that simple septic glands are liable in time to become infected by tubercle bacilli passing through the tonsils, which may or may not themselves show evidence of tuberculous deposit. A. P. Mitchell[2] found histological evidence of tuberculosis of the tonsils in 37·5 per cent. of 64 consecutive cases of tuberculous disease of the upper cervical glands, and in 6·5 per cent of 90 children who showed no evidence of tuberculosis. It is important to note that this tuberculosis of the tonsils is truly latent; the tonsils are pale, not ulcerated, and often quite small, as was pointed out by A. D. Fordyce and E. W. G. Carmichael.[3] Therefore, as it is probable that in tuberculosis of the cervical glands the portal of entry is usually through the tonsil, and as it is impossible by clinical examination to exclude tuberculosis of this organ, the wise course is to remove the tonsils in all such cases, even though they do not appear to the eye to be unhealthy. After this operation the child should be placed under the best possible hygienic conditions for several months, when in most cases the glands will have so far subsided as to render their removal unnecessary, and in other cases a much smaller dissection will be required than appeared at first to be indicated. Whether we can go back still another stage and by means of proper nasal hygiene avoid the tonsillar infection is a question that deserves attention. Nasal drill is coming to be regarded as a fundamental element in anti-tuberculosis work among children. At least 80 per cent. of children sent to sanatoriums are found to be imperfect nasal breathers, and the correction of bad respiratory habit is at least as important as an effort to fatten the child.

Potent Impurities in Anæsthetics.

EXACT research has made havoc of current notions regarding the action on the body of certain well-known drugs. It is not long since the Advisory Committee appointed by the Liquor Control Board published the disconcerting conclusion that the influence of alcohol on the human nervous system is sedative rather than stimulant, the effects usually interpreted by the consumer as evidence of stimulation being actually due to the removal of control exercised by higher nervous centres. Acceptance of this generalisation need not, however, preclude the devotees of whisky and claret from ascribing particular virtues to the ethers and essential oils which accompany the pure alcohol content. From the year 1846, when Jackson and Morton introduced ethylic ether as an adjuvant in surgery, this drug has been regarded essentially as an anæsthetic agent. It is true that as such it has not satisfied all reasonable demands, for nitrous-oxide gas has been extensively used to supplement induction of anæsthesia and various admixtures of chloroform to carry on in the later stages. But no doubt existed that the narcotic effect was due to the action of pure ethylic ether. Cushny states in the sixth edition (1915) of his Text-book of Pharmacology that ether seldom contains impurities of importance, although when exposed to air and sunlight it may contain acetaldehyde and peroxide bodies, rendering it more irritant to mucous surfaces.

Four years ago Dr. J. Cotton of McGill University claimed[1] to have discovered extraneous substances in the anæsthetic ether of commerce, one group favourable to the production of anæsthesia, which he termed synergists, and a second group of undesirable impurities responsible for mucous irritation and post-operative nausea. On his initiative an anæsthetic ether was put on the American market with certain impurities removed and with the addition of 2 per cent. by volume of ethylene, half a volume of CO_2 and 1 per cent. by weight of ethylic alcohol. Dr. J. E. Lumbard of New York City went on to show[2] that the purest ethylic ether he was able to produce possessed almost contemptible anæsthetic properties. This sample assayed 99·8 per cent. pure ethylic ether, the remainder being water, and Dr. Lumbard states "it was actually impossible to get a really satisfactory degree of surgical anæsthesia with it, in spite of any increased amount administered." And now, in the paper by Dr. R. L. Mackenzie Wallis and Mr. C. L. Hewer in our present issue, the myth of anæsthetic action is apparently finally laid, ether becoming merely a convenient vehicle for administering certain potent anæsthetic substances present in it in small quantities as impurities.

The main outcome of this work of Wallis and Hewer has been to show that most of the harmful effects of ether—and it may be added, parenthetically, of chloroform—are due to the impurities which they contain. In the case of ether the chief irritants are aldehydes and mercaptans, and when these are removed the ether is freed from any harmful effect in some respects. Further purification, they found, removed not only the irritants, but some compounds essential for anæsthesia, the remaining pure ether having an intoxicant rather than an anæsthetic action. Finally, the anæsthetic effect was discovered to be due to the presence of ketones in small quantities, and the subsequent re-addition of these ketones to the purified ether resulted in the production of a good anæsthetic mixture, free from irritant effect and almost odourless. Should further experience confirm these observations they open up a wide field for investigation, and the new product has been supplied to anæsthetists with the object of ascertaining its true value under a variety of conditions. It may be that other drugs, particularly organic chemicals, owe their main action to impurities contained in them. Thus we know that salvarsan contains sulphur in small amounts, although we do not yet know the significance of this sulphur. Differences in therapeutic effect have been observed between natural and synthetic sodium salicylate. It seems not impossible that the specific action of salicylates may be due largely to impurities; hence the necessity of giving large doses to obtain the necessary therapeutic action. Many naturally occurring organic compounds are found to be more efficacious than those synthetically prepared. All this suggests the continued need of curiosity into the active ingredients of drugs about which we were prone to regard our knowledge as complete.

THE BUFF BOOK AND THE G.M.C.

AT the February meeting of the Executive Committee of the General Medical Council the question of the insertion of the names of medical and dental practitioners in the Buff Book (being a classified commercial telephone directory for London) was under consideration, and a resolution was passed to the following effect:—

> That the insertion of the name of a medical practitioner for payment, whether with or without typographical display, in a list issued to the public, and purporting to be a list of local medical practitioners, which is not open to the whole of the profession without such payment, is not in accordance with professional standards in respect of advertising, and might be held to bring a practitioner so advertising himself within the terms of No. 5 of the Council's warning notices.

So much is, or should be, familiar to our readers. The Council's Registrar has now received a communication from the secretary of the Law Society, in which he says that he "understands that all professional men are now being admitted free of charge, provided their names are printed in small type, but that the Buff Book is not making any hard-and-fast rule that a professional man's name shall appear only in small type. They will print him in any size type he likes provided he pays for it. The Council of the Law Society, however, still feel an objection to solicitors inserting their names at all in the Buff Book, and the objection is based upon this, that some solicitors have no telephone, and that a classified list of solicitors in the Buff Book might give an undue advantage to those who have. This objection does not attach to the ordinary telephone book where names are in alphabetical order, and there is no classification."

We understand that, although no further action was taken by the General Medical Council at its recent session, the attitude of the Council remains as stated in the resolution of its Executive Committee. Should a complaint be lodged against a practitioner in regard to this matter it might be necessary for him to appear before the Council.

HARVEIAN SOCIETY OF LONDON. — The annual dinner of this society, as already announced, will take place at the Café Royal, Regent-street, on June 22nd, at 7.30 P.M. (for 7.45 P.M.), with Dr. G. de B. Turtle, the President, in the chair. The price of the dinner is 12s. 6d., exclusive of wines, and this amount will be collected by the secretaries at the entrance. It is hoped as many members as possible will attend. Those who intend to be present are asked to communicate as soon as possible with the hon. secretaries of the society, 81, Cambridge-terrace, Hyde Park, W.

Annotations.

"Ne quid nimis."

THE WAR AND INDUSTRIAL UNREST.

AT the Royal Society of Arts on May 26th Dr. C. M. Wilson read a paper dealing with Some Effects of the War on Industrial Unrest. The avowed purpose of his paper was to supply an analysis of the present mood and temper of labour, rather than to provide a cut-and-dried solution of problems of industrial unrest. He maintained that in the endeavour to allay that unrest little help is to be obtained from a study of existing institutions; we must rely mainly upon a consideration of human nature, as being the only constant in the problem under review. The difficulties of this task are not made lighter by the practical absence of a labour press in which currents of political thought can be traced. At the outset of the problem lay the necessity of distinguishing the case of the man who saw active service from that of the man who remained at home. Many of the causes of unrest are older than the war, but the mood in which labour is advancing its solutions of these problems is mainly a by-product of the four years of war. We must realise the importance of examining that mood with sympathy and understanding, for it is the outcome of trench experiences. In the later years of the war the "cooking" of war news before it was served up in the press in England was a prime factor in unsettling opinion in France; scepticism marked a decline of confidence in leadership and authority. Examination of the history of the transfer of power from the few to the many since the Reform Act of 1832 demonstrates that it was mainly attributable to the pressure of economic grievances. Abstract theories of natural rights carry little weight without such grievances; the causes of disillusionment in the trenches having no economic basis might therefore appear transitory, but we must be cautious in accepting that interpretation of them, not only because of their intensity and widespread distribution, but also because they are still in operation. The men in the trenches were gradually taught to use new standards in judging men; they are now asked to revert to older standards, associated with "getting on in life," which they had found in the trenches to be artificial standards. With that caution, we can perhaps accept the fact that the real motive force to-day is not political but economic, and that the mass of the people simply want to better their conditions. It is important to meet this wish up to the very limit compatible with the industrial state, because history tends to show that the people will only welcome sudden and sweeping changes if they have solid grievances. It must also be remembered that in handling those who saw active service we are often dealing with men rendered abnormal by the ordeal of modern warfare—men who underwent a change as part of a defensive mechanism set up to meet the environment of the trenches. This defensive mechanism tended towards apathy and what at first sight appeared to be indolence, and this may account for diminished production on the part of workmen at the present time. There is also to be considered the effect of monotony on men both during the war and in their present work, which tends to exaggerate the state of mind resulting from trench life. It is essential that the existing temper of labour be understood before remedies are advanced. Men in the mass are more critical as a result of the war, and less inclined to believe in the infallibility of the press. They have been prepared by the war for an appeal based on something higher than self-interest. This is the opportunity of the war, and it has not been taken. The ineffectiveness of words in an atmosphere of suspicion is becoming increasingly obvious. The methods of the old regular army in handling men merit consideration. The so-called indiscipline of labour is not a fact but a prejudice. The influence of lack of security is of the greatest importance in precipitating strikes; this influence is a symptom of the instinct of class preservation only to be removed by the erection of machinery for settling trade disputes in which labour really believes. The conditions of contentment are partly material and partly moral. There is no danger of the material factors being overlooked at the present day, but there is a danger of the moral factors which constitute the basis of contentment being neglected. In the past the essentials of leadership have been laid down by feudal conditions. It was Dr. Wilson's forcible plea that these essentials must now be reviewed in the light of the attributes of leadership required in an industrial state.

THE TYPHUS EPIDEMIC IN SERBIA IN 1915.

A MODEST volume[1] of 273 pages recently published contains a whole epic of human tragedy in a faithful, unvarnished account of the awfulness through which distracted Serbia lived during 1915. The epidemic of that year was one of the most severe that the world has known in modern times; it not only interrupted and suspended for approximately six months all important military activities of the Serbian army, but it also delayed the military advance of the Central Powers. During the height of the epidemic the number of new fever cases entering the military hospitals alone reached 2500 per day. How many more unreported cases actually occurred one will never know. The mortality varied between 30 and 60 per cent., and in complicated cases reached 70 per cent. Over 150,000 deaths occurred within six months before the epidemic could be suppressed, and coincident with the typhus there occurred an epidemic of relapsing fever. There were only approximately 350 Serbian doctors in the country prior to the outbreak. The majority of this small number sooner or later became afflicted with the disease, 126 succumbing, a mortality of 36 per cent. In an institution originally reserved for surgical cases, with 400 beds, there were approximately 1600 patients, 1100 of which were suffering from typhus. Of a hospital staff of 42 only three escaped the disease. There were no lavatory or bathing or toilet facilities; no nurses: and often only a few Austrian prisoners as attendants. Prison camps were veritable death-traps. Over one-half of the 70,000 Austrian prisoners in Serbia died of typhus during the epidemic. Uskub was a veritable valley of the shadow of death; tired nurses on leaving the crowded hospitals for a little fresh air and exercise were met by a long procession of bullock wagons carrying rude coffins to the cemetery. Sometimes three coffins with unfastened lids rested on the same cart, exposing the bodies of the dead. Of the six surgeons attached to American hospital units two died. Lice were ubiquitous; even the linen brought back from the laundry was not free from vermin. For some time not a single hospital possessed a steriliser. The account of the preventive measures used, now familiar to English readers, is instructive. It had been argued that in order to exterminate typhus from Serbia it would be necessary to raise the standard of living of the whole Serbian people, and entirely to change their habits—a work of years. But owing to the heroic efforts of the American and English commissions, with the coöperation of the Serbian people, the epidemic was not accompanied by starvation and famine, and after six months' intensive labour was entirely eradicated. The habits of the people even now show but little permanent change. In order to cope with the epidemic it became necessary to improvise apparatus for disinfesting and bathing on the spot; the majority of centres did not attain a high standard of efficiency, but usually served their purpose in destroying lice and their ova. Experience demonstrated that highly perfected steam machines were not absolutely essential for overcoming such an outbreak.

The discovery of the Rickettsia bodies, and the series of experimental investigations by different observers which led to their general acceptance as the cause of typhus fever, trench and Rocky Mountain fever, make an interesting story, of which a good account is given by Dr. Strong and his colleagues. The bodies were discovered by Ricketts in guinea-pigs and monkeys injected with blood from Rocky Mountain fever cases, and were also demonstrated in the body of *Dermacentor venustus*, as well as in the ova of infected ticks. In 1910 Ricketts and Wilder observed similar bodies in the blood of typhus fever cases in Mexico, and in 1913 this discovery was confirmed by Prowazek in Belgrade, while Sergent, Foley, and Vialatte in the following year observed similar organisms in infected lice during their experiments in the louse transmission of typhus in Algiers. Rocha-Lima and Prowazek confirmed these discoveries in Germany in 1916, and demonstrated similar bodies in the intestines of lice on the fourth and fifth days after feeding them on typhus blood: in the same year Wolbach in Wyoming found Rickettsia bodies in the capillary endothelial cells of guinea-pigs injected with Rocky Mountain fever blood. From 1917 onwards research was directed towards the discovery by Toepfer, Munk, and Rocha-Lima of similar bodies in the blood and infected lice from cases of a remittent fever, first described as Volhynia fever, but now more generally known as "trench fever." In 1918 Arkwright, Bacot, and Duncan definitely proved the association of these bodies in the fæces of infected lice with the production of trench fever in man. Finally, in 1918, Kuczynski demonstrated the Rickettsia bodies, now known as *Rickettsia prowazeki*, in the petechiæ of the typhus rash, and in the endothelial cells of the capillaries of the liver and other organs, work which has since been confirmed by Wolbach and Todd in the recent Polish epidemic. This, then, very briefly is the outline of the story of the discovery of the long-sought-for cause of typhus.

THE SULPHUR CYCLE, OXIDATION OF SULPHUR BY MICRO-ORGANISMS.

AMONGST the many observations and meditations of Hamlet not the least interesting are those on the mutability of matter. "A man may fish with a worm that hath eat of a king; and eat of the fish that hath fed on that worm," the reflex of that speculation addressed to Horatio: "Why may not imagination trace the noble dust of Alexander, till he find it stopping a bunghole." What even the vivid imagination of Shakespeare himself portrayed is outbid by the achievements of a microscopic cell or by infinitesimally small, lowly bacteria. The small things of the world confound and transform the complex and the mighty. To trace the cycle of a single chemical element in the round of Nature is both a romantic and singularly useful occupation. The latter aspect may be illustrated by the production of free organic acids—acetic, butyric, lactic—by specific micro-organisms, or by mineral acids the products of animal cells, or by micro-organisms. One of the gasteropods contains so much pure sulphuric acid in its saliva, that when it falls on a marble floor it causes effervescence. Again, in the whole round of the vertebrates free hydrochloric acid is always present in gastric juice. It is interesting to note that parotid saliva—alone of all the secretions poured into the mouth—contains an organic compound of sulphur, the sulpho-, or thio-cyanide of potassium, while the bile contains sulphur in its taurin, and every hair or epithelial cell when shed removes in the keratin a certain small amount of sulphur. The liver cell has the remarkable power of fixing organically certain sulphur combinations, which are excreted in the urine. There is, however, a group of microbes which deal specially with sulphur compounds by way of oxidising the sulphur. Winogradsky many years ago was the first investigator definitely to demonstrate the rôle of microbes in the oxidation of H_2S, and of the latter to H_2SO_4. Only about thirty years after, Keil isolated these two organisms—*Beggiatoa* and *Thiothrix*. They never turned the medium acid; this was explained by the presence of sufficient $CaCO_3$ in the culture to neutralise any acid formed. There are various groups of sulphur-oxidising bacteria; the two forms above mentioned accumulate sulphur within their cells. Other forms—*Thiobacillus denitrificans* is anaerobic, deriving its oxygen from the decomposition of nitrates, and *T. thioparus*, which oxidises thiosulphates, H_2S, and S—do not accumulate sulphur within their cells, but produce abundance of sulphur outside their cells and cause the medium to become distinctly acid. Mr. Selman A. Waksman and Mr. J. S. Joffe, of the New Jersey Agricultural Experiment Station, New Brunswick, have isolated another group of bacteria, closely allied morphologically to the latter group, which do not act upon thiosulphates and H_2S, but act only upon elementary sulphur, and allow the medium to become very distinctly acid. They were isolated from certain composts by means of a purely inorganic culture-medium, consisting of minerals, with elementary sulphur as the only source of energy. These organisms are very remarkable, are autotrophic, and do not need any organic substances for their development, the carbon being supplied from the CO_2 of the air. The sulphur is oxidised very rapidly with the production of sulphuric acid. In the presence of the proper neutralising agents, salts or acid salts are formed which tend to make the medium less acid. The noteworthy thing about this group of bacteria is that they produce a more acid zone than the final acidity of the majority of acid-producing bacteria (lactic, acetic, &c.) and yeasts, and they produce a greater concentration of acids and remain alive in that acid medium. The authors' object is the production of acid at such a rate and under such conditions that it should transform insoluble tricalcium phosphate into soluble phosphates and phosphoric acid, the insoluble phosphates being used as neutralising agents But the whole story of the rôle of sulphur in bacterial life remains to be told.

[1] Typhus Fever, with Particular Reference to the Serbian Epidemic. By Richard P. Strong, George C. Shattuck, A. W. Sellards, Hans Zinsser, and J. Gardner Hopkins. Published by the American Red Cross at the Harvard University Press, Cambridge, Mass. 1920. Pp. 273.

SUNSHINE, SLEEP, AND HEALTH.

THE medical department of the Board of Education has just issued to local education authorities a circular (No. 1215) which institutes an inquiry into the operation of the Daylight Saving Act in regard to any injurious effect upon the health of school children. The report of the Summer Time Committee in 1917 showed that in Scotland 80 per cent., and in England 46 per cent., of education authorities reported no evidence of curtailment of sleep as a result of the alteration of the clock face. The high percentage of negative answers from Scotland, where summer daylight is normally more prolonged than in England, is a testimony to a higher standard of parental control and sense of responsibility north of the Tweed. Southron parents must learn to understand that children of school age should not be kept out of bed until dark. Education authorities might usefully draw the attention of parents to the paramount necessity of sufficient rest in bed for young children. The mere fact of their not sleeping at the beginning and end of bed rest is of no great importance. All young animals naturally sleep less in summer than in winter; there is less demand on metabolism in warm weather and consequently less need for sleep. Children have always been kept out of bed later in the summer than in the winter time, and the fact has been a source of lament to teachers for generations. But they are apt to forget this periodicity and to put down to the Daylight Saving Act what is a yearly occurrence. Statistics show that more children die of winter than of summer ailments, and there can be little doubt that the prolonged sunlight of early summer is even more beneficial to growing children than it is to adults.

THE PATHOLOGY OF HYDROCEPHALUS.

THE researches of Mr. W. E. Dandy, of the Department of Surgery of the Johns Hopkins Hospital, have revolutionised as well as simplified our knowledge of the pathology of hydrocephalus. In 1913, in conjunction with K. D. Blackfan, he showed that any lesion which occludes the ventricular system will always produce stasis of fluid and dilatation of the ventricles proximal to the obstruction, but will not change the size of the ventricles distal to it.[1] In a recent paper[2] he has shown that the cause of the other form of the disease—communicating hydrocephalus—i.e., the form in which all the ventricles are in communication with the subarachnoid space, is similar. In studying the absorption of cerebrospinal fluid in hydrocephalus, Dandy and Blackfan found that in the communicating form absorption from the subarachnoid space is greatly reduced. This suggested reduction in the amount of absorption space. Later, in cases studied at necropsy, adhesions were found which obliterated the cisternæ. Hence it was assumed that, by preventing the cerebro-spinal fluid from reaching the great absorption spaces over the cerebral hemispheres, these adhesions caused hydrocephalus. This was proved by experiment. An obstruction of the cisternæ may be demonstrated in two ways—after death and during life. If a coloured suspension is injected into the spinal canal before making a necropsy the colour will reach but not pass an obstruction in the cisternæ. The cause of communicating hydrocephalus may also be shown by its experimental production. In dogs the mesencephalic cisterna was blocked by surrounding the midbrain with a piece of gauze saturated with iodine. Shortly before necropsy a suspension of Indian ink was substituted for an equal amount of cerebro-spinal fluid, which had been aspirated from the cisterna magna through a puncture in the occipito-atlantal membrane. When Indian ink is introduced into the spinal canal of an animal with intact cerebro-spinal spaces, the colour will find its way to every point of the subarachnoid space over both cerebral hemispheres. But in animals with the perimesencephalic barrier the passage of the ink is abruptly terminated there, and none reaches the hemispheres. Further, hydrocephalus develops and the foramina of Luschka and Magendie become so dilated that a retrograde flow of ink takes place into the cerebral ventricles. In one case of communicating hydrocephalus the opportunity arose of verifying this fact in man. The colour was introduced post mortem by gravity for 15 to 20 minutes—pressure was not used for fear of rupturing delicate adhesions. The colour filled the cisternæ, even the cisterna interpeduncularis, and covered the cerebellar subarachnoid spaces, but failed to reach the cerebral hemispheres. On the other hand, the ink passed freely into every part of the cerebral ventricles, for the foramina of Luschka and Magendie were widely open. The cerebro-spinal fluid circulates in a mesothelial-lined vascular system just as definite as the blood vascular. The cerebral ventricles are concerned only with the production of cerebro-spinal fluid, and the spaces on the exterior of the brain (subarachnoid) normally only with its absorption. The fluid passes from the former to the latter through the foramina of Luschka and Magendie. Hence, when these are obstructed hydrocephalus of all the ventricles is produced. But in communicating hydrocephalus they are open and the fluid reaches the cisterna magna and then passes under the medulla, pons, and midbrain to the cisterna interpeduncularis and chiasmatis, whence it is distributed to the cerebral sulci, where it is absorbed. It has been shown experimentally that about three-fourths of the cerebro-spinal fluid is absorbed in the subarachnoid spaces of the brain and the remainder in the spinal subarachnoid space. An obstruction in the cisternæ under the medulla, pons, or mesencephalon will produce hydrocephalus just as effectually as a block in the aqueduct of Sylvius. An interesting method of demonstrating during life an obstruction in the subarachnoid space has been devised. By lumbar puncture 30 to 60 c.cm. of fluid are removed and an equal volume of air is substituted. If there be no obstruction every part of the subarachnoid space will be visible in a radiogram; the cerebral sulci will be seen as a network. If hydrocephalus be present it cannot be of the communicating form. But if air is absent in the sulci an obstruction must exist in the subarachnoid space.

LEGALISED CHILD ADOPTION.

THE Committee appointed last August by the Home Secretary to consider the desirability of making legal provision in this country for the adoption of children has just brought in a very practical and serviceable report.[1] Soon after getting to work a brief interim report was issued recommending immediate amendment of the law so as to secure the legitimation of children born out of wedlock by the subsequent marriage of their parents. An enactment to this effect, which has already been embodied in a Bill read a second time in the House of Commons, would secure the rights of one considerable group of unfortunate children. The present report proposes two further alterations in the law, both urgent. First, an Act to give legal recognition to the adoption of children under the judicial sanction of county courts, securing both for adopter and adopted child similar rights and duties to those obtaining between natural parents and their children. Such an enactment would give to the adopter that protection which has heretofore been so sadly lacking. Parents who have habitually neglected a child, and left it to be brought up by relatives or strangers, are all too ready to claim it again on reaching the wage-earning age. Such a catastrophe has occurred to many adopters and deterred others from adopting. The second recommendation is an amendment of the Children Act, 1908, whereby so-called adoptions which do not receive formal legal sanction should be notified and properly supervised. Here the provision would be for the protection of the child, for whom in many cases a monetary consideration has arisen. When these three questions have been dealt with by separate Acts the Committee recommends the reconsideration of the whole legislation relating to children with a view to amendment and consolidation. The personnel of the Committee, which has discharged so wisely and quickly its civic duties, consists of Sir Alfred Hopkinson (chairman), Mr. Neville Chamberlain, Hon. Lady Norman, Mrs. C. E. B. Russell, Mr. J. H. Seddon, and Mr. T. W. Sherwood. We are grateful to them, and trust that Parliament will lose no time in setting the seal upon their labours.

THE EPIDEMIOLOGY OF THE MENINGOCOCCUS.

ONE of the most illuminating and suggestive papers hitherto published on the peculiarities of the meningococcus has recently appeared under the signatures of Prof. O. Thomsen and Dr. Ferdinand Wulff of the Serum Institute in Copenhagen.[2] The starting-point of their theories would seem to be the observation that in no case has more than one type of meningococcus been found at the same time in the naso-pharynx of a "carrier." Interpreting this observation as a sign of mutual antagonism between the different types of meningococcus, the authors make the interesting suggestion that, with regard to the meningococcus at any rate, there are two totally different kinds of immunity. The one is due to the antibodies present in the blood and, to a less extent, in the secretions of the naso-pharynx. The other is due to the "carrying" of harmless or comparatively harmless types of meningococcus which allow no foothold for a virulent type. This second kind of immunity is, in the authors' opinion, the chief factor which renders long service soldiers comparatively unsusceptible, while recruits seem to be peculiarly susceptible. Under the often overcrowded conditions of military service, both avirulent and virulent types of meningococcus are frequently to be found in the naso-pharynx, and in the case of a recruit who joins an old draft of soldiers, there is a race between the avirulent and virulent types. If the latter reaches his naso-pharynx first, and if his concentration of antibodies is low, he falls ill or, if his concentration of antibodies is high enough to prevent serious blood infection, but not high enough to prevent lodgment in the naso-pharynx, he becomes a "carrier" of this type and is a serious danger to his fellows. The authors describe an epidemic of cerebro-spinal fever among recruits lodged in barracks, one side of which was much more damp and dark than the other. Soon after the outbreak every soldier was examined, and the "carriers" of the virulent type A (which appears to be totally distinct from the virulent types identified in this country) were isolated and the epidemic was checked. An instructive feature of this investigation was the discovery that, though the soldiers were equally divided between the two sides of the barracks, many more harboured meningococci on the dark and damp side than on the other, the actual figures being 22 to 9. Similar observations have been made by Danish army surgeons in earlier years, and the authors suggest that the explanation for this phenomenon is to be found in the lowered resistance of the body to infection induced by darkness and other unfavourable atmospheric influences. The authors translate their hypotheses into certain recommendations on behalf of recruits in their relations with old service men who may prove to be "carriers" of the dangerous type, and it appears from a note in *Hospitalstidende* for March 2nd that these recommendations have already been adopted by the Danish army authorities.

THE PNEUMOCOCCUS AND STREPTOCOCCUS IN RELATION TO INFLUENZA.

THE current number of the *Edinburgh Medical Journal* contains a valuable report on this subject made by Dr. W. R. Logan to the Medical Research Council. The plan of investigation adopted was to examine cases of (1) pure influenza in their earliest stage of illness, and (2) pulmonary complications in the more advanced stages of the disease. In the early cases where there was no sputum the material was obtained from the naso-pharynx by means of a swab, whilst in the later pulmonary cases sputum was available for examination. All the cases were obtained during the influenza epidemic in Edinburgh from November, 1918, to February, 1919. Dr. Logan examined 44 cases of pure influenza and 64 cases of pulmonary complications. From 13·6 per cent. of the former and 78·1 per cent. of the latter pneumococci were obtained, and from 100 per cent. of both groups streptococci were obtained. In differentiating the pneumococcus from the streptococcus the bile solubility test was used as the final arbiter of distinction. Thirty-four pneumococcal strains were examined as to type on the well-known lines of work of the Rockefeller bacteriologists, and 26 strains of Type IV. obtained. Nearly all these Type IV. strains were virulent to mice, whilst their cultural characteristics strongly suggested that in reality they were different strains. An attempt to subdivide them by means of serological and fermentation tests proved unsuccessful. Dr. Logan very wisely concludes that Type IV. is not a type at all, but merely a heterogeneous collection of strains which do not fall into the grouping of Types I., II. and III. In the absence of satisfactory agglutination tests for streptococci Dr. Logan used the hæmolytic test as the best means of differentiation. Non-hæmolytic streptococci having the morphological and cultural characteristics of saprophytic streptococci largely predominated, but 11 strains from 8 cases were found to be definitely hæmolytic and were virulent to mice. Several interesting questions naturally arise as the result of Dr. Logan's valuable work. Probably the most important is the place in bacteriology which must be assigned to the heterogeneous Type IV. of the pneumococcus group. The predominence ot this type in the number investigated is striking, and serves to show how relatively valueless is the ordinary routine bacteriological examination for this organism or group of organisms. Another question, perhaps closely allied, is the high proportion of apparently purely saprophytic streptococci found, as compared with the hæmolytic pathogenic varieties. Clearly we are in urgent need of some more satisfactory means of differentiating the various members of this large unwieldy group of organisms.

[1] Report of the Committee on Child Adoption. Cmd. 1254. H.M. Stationery Office. Price 2d.

[2] Hospitalstidende, 1921, vol. lxiv., Nrs. 2 and 3.

In the main Dr. Logan's conclusion as to the bacterial flora of the late influenza epidemic agrees with and supplements the tentative conclusions arrived at by Sir Frederick W. Andrewes in the Report on the Pandemic of Influenza, 1918–19, published by the Ministry of Health last year. More bacteriological material is now to hand than was available when that report was compiled. We note, for example, in the June number of *Medical Science* a considerable number of abstracts from various British and foreign journals dealing with this aspect of the question. Dr. Logan concludes by dividing influenza from the toxin point of view into three stages: "A primary stage when the unknown infecting virus of the disease is apparently *acting* alone, though presumably frequently accompanied by other organisms which may or may not later be able to develop a like activity; a secondary stage, when pathogenic pneumococci and streptococci are active in producing pulmonary complications; and a tertiary stage, when saprophytic mouth organisms may invade the already diseased lung." Probably this is quite as far as we can justifiably go along the road of causation at the present moment, but it is interesting to note how much we have all been shaken in our views of Pfeiffer's *B. influenzæ* during the last four years.

THE JOURNAL OF OBSTETRICS AND GYNÆCOLOGY OF THE BRITISH EMPIRE.

THIS journal appeared for the first time in January, 1902, and the aim of the promoters was to make the journal an impartial and complete record of British work, an exponent of British obstetrical and gynæcological practice, and an encyclopædia of contemporary thought and achievements in obstetrics and gynæcology throughout the world. In this the various distinguished occupants of the editorial chair succeeded admirably. Unfortunately the outbreak of the war and the fact that a large number of the younger men practising obstetrics and gynæcology were called up on active service, and that those left at home were fully occupied in other ways, led to its ceasing to exist for the time being. It is now proposed to revive it, and the first number of Vol. XXVIII. of the new series has just appeared. If the journal is to be a success it must receive the loyal support of all those who practise this branch of medicine, and they must assume the responsibility not only of supporting the new venture financially, but also of helping it by contributing to its columns. The number of young obstetricians and gynæcologists has much increased of recent years, and many new developments have taken place in this department of practice. There should be ample scope for such a journal, and it would be little short of a scandal if sufficient support is not forthcoming not only to keep the journal alive and flourishing, but also to maintain the very high reputation it has had in the past. There are numerous problems awaiting solution both in midwifery and gynæcology, and it is to be hoped that the number of workers in this field of research will be greatly increased. There is ample room for them and no lack of material. The new editors, Dr. Comyns Berkeley and Dr. Eardley Holland, will be happy to receive contributions.

GOVERNMENT SURPLUS MEDICAL STORES.

ENORMOUS stocks of medical and surgical material, instruments, and drugs still exist, and the question has arisen as to the best way in which these large quantities can be most usefully employed. The Disposal Board decided to invoke the assistance of the Joint Council of the Order of St. John and the British Red Cross Society. Sir Napier Burnett, who is the chief executive officer of the Joint Council, considered that it would be wise to collect into one place the stores which were scattered about in every part of the country. This has been done and they have been housed near Shepherd's Bush in a large building in the grounds of the Disposal Board; and there all the instruments and material have been classified and arranged for exhibition. A private view of them was given on Monday last to representatives of a large number of newspapers. A written description can give but a faint idea of the very great quantities that are available; the stores must be seen for their extent to be appreciated. Some idea of the quantity available can be obtained from the statement that the original cost has been estimated to have been about a million pounds. There are over half a million of surgical instruments, and approximately 50 tons of drugs of nearly every variety. 130 million tablets are available, including five million of the famous "Number 9" pill. In view especially of the anxious financial position of the hospitals of this country at the present time it has been resolved to offer these stores to the hospitals at very reasonable prices, and for this purpose they are to be open to view by representatives of the hospitals in rotation; about 100 hospitals are to be invited each day, but nothing will be sold until all the hospitals have had an opportunity of inspecting them, so that in about a fortnight the sales to hospitals will begin. Current will be available for the testing of the X ray apparatus by intending purchasers. It is clear that the arrangements have been devised with the greatest care, and the hospitals will doubtless find this an excellent opportunity of obtaining at a moderate price what they need. Sir Howard Frank, the Commissioner of the Disposal Board, presided at a luncheon held at the Royal Automobile Club after inspection of the stores. He was supported by Sir Arthur Stanley, Chairman of the Joint Council, Sir Napier Burnett, and Major-General Sir L. B. Friend, member of the Disposal Board. Sir Howard Frank, Sir Arthur Stanley, and Sir Napier Burnett explained the mode in which it is intended to dispose of the stores, and they expressed the hope that the arrangements made would be to the benefit of the hospitals, and at the same time would result in a substantial addition to the funds of the Government. The scheme has been carefully thought out, and should work well.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, MAY 24TH.

THE address delivered by the PRESIDENT was reported in last week's issue of THE LANCET. At its conclusion a vote of thanks to the President was carried by acclamation.

Appointment of Committees.

The following committees were appointed :—

Business Committee.—Dr. Norman Walker (chairman), the President, Sir Francis Champneys, Dr. Magennis, Dr. Macdonald.

Pharmacopœia Committee.—The President (chairman), Dr. Caton, Dr. Matthew Hay, Dr. Kidd, Dr. Hopkins, Dr. Norman Walker, Sir John Moore, Sir Norman Moore, Dr. Russell Wells.

Finance Committee.—Sir Norman Moore (chairman), the President, Mr. Waring, Sir James Hodsdon, Sir Arthur Chance.

Dental Committee.—The President (chairman), Mr. Bennett, Sir James Hodsdon, Mr. Waring, Sir Arthur Chance.

Dental Education and Examination Committee.—Sir James Hodsdon (chairman), the President, Mr. Bennett, Mr. Waring, Dr. Adams, Sir E. Coey Bigger, Sir Arthur Chance.

Students' Registration Committee.—Sir Norman Moore (chairman), Sir Gilbert Barling, the President, Mr. Littlejohn, Dr. Mackay, Dr. Kidd, Mr. Sinclair.

Penal Cases Committee.—The President, Sir Francis Champneys, Sir Arthur Chance, Dr. Norman Walker, Dr. Macdonald.

Executive Committee.—The President, Sir Gilbert Barling, Sir James Hodsdon, Dr. Macdonald, Dr. Norman Walker, Sir Norman Moore, Sir Arthur Chance, Mr. Waring, Sir John Moore.

Reports of Finance and Education Committees.

The report of the Finance Committee was then received and approved, after which the chairman of the Education Committee made an oral report to the Council, calling the attention of the Council and of medical schools generally to the changes in the Medical Students' Regulations which had been made since the last meeting, embodying the resolutions adopted by the Council in November. He explained that the examination in the preliminary sciences was intended to be separate and distinct from the preliminary examination in general education; and also informed the Council that the Education Committee had recognised the shortened matriculation examination of the University of London, and also the senior public examination of the University of Queensland, and that these would be inserted in the next published list of examinations recognised by the Council.

Penal Cases.

The Council then proceeded to the consideration of penal cases.

The Case of Frederick Percy Richard Gover.

The Council considered the case of FREDERICK PERCY RICHARD GOVER, registered as c/o Pearce and Sons, 58, West Smithfield, E.C. 1, L.R.C.P. Edin., F.R.C.S. Edin., L.R.F.P.S. Glasg. 1910, who had been summoned to appear before the Council on the following charge :—

> That being a registered medical practitioner you were convicted of the following misdemeanours, viz. :—On June 9th, 1916, at the Marlborough Street police court, of being drunk in charge of a motor-car and fined forty shillings. On the same day of driving in a dangerous manner and fined twenty pounds. On Dec. 26th, 1916, at the Tower Bridge police court, of being drunk in charge of a motor and fined two pounds or one month's imprisonment. On the same day of driving a motor-car recklessly and fined ten pounds or one month's imprisonment. On April 9th, 1917, at the Hove Borough police court, of being drunk in charge of a motor-car and sentenced to one month's imprisonment with hard labour and disqualified from holding a licence for six months, which sentence was modified on your appeal to the East Sussex Sessions to one month's imprisonment in the second division, but otherwise affirmed. On Nov. 9th, 1920, at the County of London Sessions, held at the Session House, Clerkenwell, of having caused bodily harm to Mary Ann King by wilful misconduct or by wilful negligence whilst having the charge of a motor-car, and ordered to be imprisoned for three months and to be treated as an offender of the second division.

Mr. Gover attended, accompanied by Mr. Watts, his counsel.

The Council's solicitor, Mr. Harper, laid the facts of the case before the Council. He read a report of the proceedings at the County of London Sessions in November, 1920, and a police report on the case. He also read a report of an inquiry under the National Health Insurance Acts concerning the convictions, and the decision of the Ministry of Health on the report thereon. Mr. Watts then opened the case for the defence. He called Mr. Gover, and examined him as a witness in his own behalf. Mr. Gover answered questions put to him by members of the Council through the chair. The Council's solicitor did not desire to cross-examine Mr. Gover. He put in two petitions organised on behalf of Mr. Gover by panel patients and by the police. Mr. Watts then addressed the Council on behalf of Mr. Gover. The Council's solicitor addressed the Council in reply. This closed the case.

The Council having deliberated on the case in camera, the PRESIDENT announced the judgment of the Council as follows :—

I have to tell you that the alleged convictions against you in the notice have been proved to the satisfaction of the Council. These convictions indicate a habit which is not only discreditable to your profession but may become dangerous to your patients. In order to give you an opportunity of reconsidering your habit in this matter the Council has postponed judgment on the convictions proved against you till the May session, 1922. Before that date you will be required to send to the Registrar of the Council the names of some of your professional brethren who may be willing, upon written application from the Registrar, to testify by letter, addressed to him for the use of the Council, as to your character and conduct in the interval. You will receive in due course a formal written intimation of what I have just announced to you, and the intimation will specify the date to which I have referred, when you should be present, and should understand that in the event of any further conviction for a similar offence the Council may instruct the Registrar to erase your name from the Medical Register.

On invitation from the chair, Mr. Gover renewed his solemn undertaking to refrain from drink for the rest of his life.

The Case of Clement Thomas Cory Kingdon.

The Council considered the case of CLEMENT THOMAS CORY KINGDON, registered as of 62, Falcon-road, Clapham Junction, S.W. 11, M.B., C.M. 1893, M.D. 1905 U.Edin., who had been summoned to appear before the Council on the following charge :—

> That, being a registered medical practitioner, you, on Feb. 7th, 1921, signed and gave to one W. McKernon, ex-member of the Australian Imperial Force, a certificate dated Feb. 5th, 1921, that the said W. McKernon was suffering from influenza, and was at present (i.e., on Feb. 5th, 1921) unable to travel, whereas you had neither seen nor examined the said W. McKernon on Feb. 5th, 1921, or at all before Feb. 7th, 1921. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

The complainant was the Australian Imperial Force. Dr. Kingdon attended in answer to his notice, accompanied by Mr. Hempson, solicitor to the Medical Defence Union, his solicitor. The Australian Imperial Force, the complainant, was represented by Major F. M. Best, A.I.F., solicitor, of Messrs. J. Galbraith and Best, Australia House, Strand, W.C. 2. The President inquired whether any member of the Medical Defence Union was present. No such member was present. Major Best then opened the case on behalf of the complainants. He called Major E. W. Morris as a witness and examined him as to the truth of his statutory declaration. Major Morris was cross-examined by

Mr. Hempson, and answered questions put to him, through the chair, by members of the Council. Major Best did not desire to re-examine Major Morris. This closed his case.

Mr. Hempson called Dr. Cory Kingdon as a witness, and examined him as to the truth of his statutory declaration. Dr. Kingdon was cross-examined, answered questions put to him by the Legal Assessor and by members of the Council through the chair. Mr. Hempson read statutory declarations as to Dr. Kingdon's good character from Dr. Philip Rashleigh Dodwell, assistant resident medical officer to the Brompton Consumption Hospital, and from Dr. James Smith, deputy medical officer to His Majesty's Prison, Wandsworth.

The Council having deliberated the case in camera, the PRESIDENT announced the decision of the Council as follows:—

I have to inform you that the Council has found that the facts which were alleged against you in the notice of inquiry have been proved to its satisfaction, but that the Council has taken into consideration the evidence as to your previous good character, and your assurance that the certificate was given without due care and thought. In order to give you an opportunity to rehabilitate your character and to prove to the Council that you realise the gravity of your offence, and in particular in regard to the giving of certificates, the Council has postponed judgment till the November session, when you will be required to attend and to produce evidence from your professional brethren regarding your character.

The Council then adjourned.

WEDNESDAY, MAY 25TH.

The earlier part of this day's session was occupied with the hearing of penal cases.

The Case of John Thomas Godfrey.

The Council considered the case of JOHN THOMAS GODFREY, registered as of Royton Hall, Royton, Oldham, M.B., Ch.B., 1917 U.Edin., who had been summoned to appear before the Council on the following charge:—

That being a registered medical practitioner, you were, at the Manchester Assizes, held on Nov. 15th, 1920, convicted of the following misdemeanour, namely, of attempting to obtain money by false pretences and fraudulent conversion of goods and ordered to be imprisoned for three calendar months.

Mr. Godfrey attended accompanied by counsel. The Council's Solicitor laid the facts of the case before it. He read the statement by Detective-Inspector Quayle in regard to the conviction which he put in, and read extracts from the report of the proceedings of the Insurance Acts Committee which inquired into the conviction. Counsel for the defence then addressed the Council on behalf of Mr. Godfrey, and handed in a series of testimonials in his favour, including testimonials from Dr. J. Sinclair McGowan, Mr. Henry Beswick, J.P., chairman of the Royton District Council, Dr. J. Lorrain Smith, Dean of the Faculty of Medicine of the University of Edinburgh, from Mr. Timothy Cusock, parish priest of Royton, from Mr. John Lindley of the Manchester Royal Exchange, and from Mr. Godfrey's schoolmaster at Durban. The Council's Solicitor addressed the Council in reply.

The Council having deliberated on the case in camera, the PRESIDENT announced the judgment of the Council as follows:—

I have to inform you that you, having been proved to have been convicted of the misdemeanour alleged against you in the notice of inquiry, the Registrar has been directed to erase your name from the Medical Register.

The Case of George Ormiston.

The Council considered a report by the Dental Committee on the charge against GEORGE ORMISTON, in regard to whom certain facts had been found. Mr. Ormiston was not present, nor was he represented by counsel or solicitor. Mr. Hugh Atkins, general secretary of the British Dental Association, the complainants, was present. The Registrar read the following report on the case:—

The complaint against George Ormiston having been referred to the Dental Committee to ascertain the facts, the Dental Committee reported as follows:

On May 23rd, 1921, the complainants, the British Dental Association, represented by Mr. Hugh Atkins, the general secretary of the Association, attended before the Committee and were duly heard. The said George Ormiston did not attend before the Committee, nor was he represented by solicitor or counsel. The chairman asked at the opening of the inquiry whether any member of the British Dental Association was present on the Committee. No member of the Association was present. The Committee find that the following facts were established by the evidence:—

The said George Ormiston was registered on Dec. 27th, 1878, as "In practice on July 22nd, 1878." His address in the current Register is 170, Skene-street West, Aberdeen. Up to a recent date there were exhibited at 170, Skene-street West, aforesaid, the following:—

(*a*) On the window in gilt letters the words:—

Dentist: Mr. Ormiston, Mr. Thow.

(*b*) On the front railing a wooden sign with the words painted thereon: Ormiston and Thow.

(*c*) At the side entrance, painted on the stone wall, the words: Mr. Ormiston.

In the *Aberdeen Free Press* of Dec. 7th, 1920, and March 18th, 1921, under the heading "Artificial Teeth," appeared an advertisement "Ormiston and Thow, Surgeon Dentists" (Dec. 7th, 1920), and "Ormiston and Thow" (March 18th 1921), advertising also painless extractions, gas, skilled work and moderate charges at 170, Skene-street West, aforesaid. In the telephone directory of the Aberdeen district dated February, 1921, is the entry: "Central 2601: Ormiston and Thow, Surgeon Dentists, 170, Skene-street."

Thow, who has never been on the Dentists' Register, was trained by the said George Ormiston as a pupil, and had up to April 28th, 1921, been in his employment for 20 years. The said George Ormiston stated this in a letter to the Registrar, adding that Thow was a most skilful operator and mechanic, and that he, George Ormiston, had been compelled to use his services owing to his own health giving way. In a letter dated May 13th, 1921, from the solicitors of the said George Ormiston, it is stated that he has definitely and finally retired from dentistry practice, and he applies to be allowed to withdraw his name from the Register. The letter adds that the said George Ormiston has withdrawn his name entirely from 170, Skene-street, and that all financial and professional connexion between him and Thow have ceased, with the exception that Thow has only now to pay for the fixtures, furnishings, and material which are identified with the dentistry practice.

In the absence of further information (the said George Ormiston not having been present at the inquiry or represented), the Dental Committee infer that on receipt of the notice of inquiry he parted with his practice to Thow for a consideration, and that this has not yet been fully discharged. The said George Ormiston sent to the Registrar through his solicitors a certificate from George Williamson, M.B. 1886, U. Aberd., dated May 13th, 1921, certifying that he was unable to travel to London on account of physical infirmity, and that he had suffered for some years from heart disease, for 12 months from angina, and for some months from religious melancholia; that it was extremely unlikely that he could ever work at his profession again, and that for a year he had practically done no work.

The evidence before the Committee consisted of the following documents, viz.:—(1) A statutory declaration by Macbeth Moir Duncan, dated April 19th, 1921; (2) and (3) advertisements from the *Aberdeen Free Press* of Dec. 7th, 1920, and March 18th, 1921; (4) letter from the said George Ormiston to the Registrar, dated April 28th, 1921; (5) letter from Alexander and Wm. Robertson to the Registrar, dated May 13th, 1921; (6) certificate of George Williamson, M.B., to the Registrar, dated May 13th, 1921.

The PRESIDENT inquired whether any member of the British Dental Association was present. No such member was then present. In answer to a question from the chair, Mr. Atkins intimated that he did not desire to address the Council on the facts found in the report. The Council having deliberated on the report in camera, the CHAIRMAN announced its decision as follows:—

Mr. Atkins, I have to announce to you that in the facts found in the report of the Dental Committee it has been found that George Ormiston has been proved guilty of the charges, and the Council has directed the Registrar to erase from the Dentists Register the name George Ormiston.

Yearly Tables and Inspection of Final Examinations.

Dr. NORMAN WALKER (chairman of the Examination Committee) presented the report of the Examination Committee on the Yearly Tables and on the Inspection of Examinations. The Council's Committee state that in accordance with their recommendation adopted by the General Council on June 2nd. 1920, the annual tables showing for 1920 the results of examinations for qualifications primarily admitting to the Medical Register have not been printed. The following analyses of those which concern the Committee have been prepared as usual.

Of the 23 bodies granting primary qualifications, it will be seen that the returns for 1920 are complete so far as they go. The table concerned with higher qualifications calls for no special comment by the Committee. The table dealing with exemptions shows that these are again exceptionally numerous. As before, many of them are directly or indirectly due to the war: others to an increasing readiness to accept the examinations of other bodies.

The inspection of the final examinations is not yet completed. That in medicine is almost finished, but there are still seven bodies to be inspected in surgery and eight in midwifery. It is highly desirable that all these should be completed before November in time for consideration at the autumn session of the Council.

* At these examinations Medicine, Surgery, and Midwifery must be passed at one time.
† Medicine, Surgery, and Midwifery must be passed at one time, except in case of certain old students.
§ Medicine, Surgery, and Midwifery must be entered for at one time.

On June 2nd, 1920, the General Medical Council, by resolution, adopted the following recommendation of the Examination Committee:—

"That the licensing bodies which have not hitherto supplied in their annual return information as to whether they do or do not examine in operative surgery, ophthalmology, and mental disease, be asked to do so in future." (Minutes, 1920, p. 21.)

This resolution was communicated by the Registrar to the bodies concerned. As a result, the information given respecting the examinations held during 1920 is much more complete than that obtained regarding those held in 1919, as the following comparative table will show:—

	1919		1920
Operative Surgery:—

Appointment of Branch Councils.

The following Branch Councils were appointed:—

Education Committee.—England: Sir F. Champneys, Dr. Howden, Sir Norman Moore; *Scotland:* Dr. Adams, Dr. Russell, Dr. N. Walker: *Ireland:* Sir Arthur Chance, Dr. Coffey, Sir John Moore.

Examination Committee.—England: Sir G. Barling, Dr. Caton, Dr. Macdonald; *Scotland:* Dr. Adams, Dr. Russell, Dr. N. Walker; *Ireland:* Sir Arthur Chance, Dr. Coffey, Sir John Moore.

Public Health Committee.—England: Dr. Dean, Sir G. Newman, Sir T. Jenner Verrall; *Scotland:* Dr. Matthew Hay, Mr. Littlejohn, Dr. McVail; *Ireland:* Sir E. Coey Bigger, Dr. Magennis, Sir John Moore.

The Council then adjourned.

THE Gloucestershire Scheme for the Extension of Medical Services, which was formally approved by the Ministry of Health in April, 1920, has been steadily coming into effective operation during the past month. Out-stations are now, or will shortly be, available in the areas of the Bristol Hospital, the Cheltenham General Hospital, and the Gloucestershire Royal Infirmary, and a circular letter as been issued by Dr. J. Middleton Martin, executive medical officer, to the medical officers in charge of the stations. The scheme deals with school children, tuberculosis, venereal disease, ex-Service men referred by pensions Committees, mothers and infants under the maternity and child welfare scheme, and other groups of patients by agreement.

THE FEDERATION OF MEDICAL AND ALLIED SOCIETIES.

THE annual dinner of the Federation of Medical and Allied Societies was held on May 26th at the Café Royal, London, Sir **BERKELEY MOYNIHAN**, the President of the Federation, being in the chair. The special guests of the evening were Dr. Christopher Addison, the late Minister of Health, and his successor, Sir Alfred Mond.

The loyal toast having been drunk, Sir **BERKELEY MOYNIHAN** proposed the health of Dr. Christopher Addison, the first Minister of Health. In eloquent terms he commended Dr. Addison's scientific equipment, sympathetic attitude towards medicine, and dignity under ill-informed criticism.

Dr. **ADDISON** thanked the Federation for the warm reception of the words from the chairman, and said that he especially valued the opinion of a body whose "aim is wide and public spirited, and marks a thoroughly wise departure from the usual purposes of professional associations. It is to promote in the medical profession the means whereby societies and associations of widely different aims from the professional or technical point of view may come together to consider not their own interests only, but in what manner they can work together for the public good, how the work of central or local governmental authorities affects the work of the medical profession and how it may best be guided and helped."

The Community of Medical Interests.

Dr. Addison then pointed out that the medical profession is not simply a body of trained men with work and interests bounded by a professional ring fence. If there was one lesson of the war, he thought, more manifest than another (though there were signs that it is being forgotten) it is that, in the language of the Scriptures, "we are members one of another." The strength or weakness of one class must be the strength or weakness of the rest, to be revealed in the time of stress, and conversely the progress and prosperity of any one class could not be promoted at the expense of the rest of the community, but would be conditioned by their progress and prosperity. He continued:—"The Federation seeks to foster in the profession a lively interest in public questions, and is confronted with peculiar difficulties, for the absorbing nature of medical practice leads to a detachment from public issues, making it difficult for medical men to appreciate the task of those who are associated with the work of government and its many-sided complications. Therefore it is hard for medical men to provide in considered and collective form the assistance which they are fitted to render to public authority. But society will seek more and more to enlist the aid of those who can help it to promote the physical well-being of its citizens—for the strength of the State is measured by the capacity of its individual members—and you all know how great is that mass of avoidable disability. In the early stages of the Ministry of Health its dominant purpose was necessarily the development of preventive agencies, primarily with the authority of the State, though the executive agents must, for the most part, be members of the medical or closely allied professions. We had and we have to take long views and be willing to create agencies and set work going that must take time to develop and to achieve results. Opportunist spectacular performances are not the function of a Ministry of Health. If they were to be, they would destroy any chance of achievement of its great and governing purposes."

Port Sanitary Work during the War.

Dr. Addison illustrated his meaning by pointing out that when the Ministry was established improved organisation of sanitary work at ports with suitable expert aid and laboratory equipment was arranged, so that the country should escape the various pestilences let loose by the war. "For this purpose," he said, "I inaugurated a system of assistance to Port Sanitary Authorities which they both needed and thoroughly deserved, whereby additional assistance of a suitable kind was available where required. So far as cost is concerned, the total of this effort is represented by a sum of £65,000 in this year's Estimates. It is a small figure compared with the millions people talk about when we are coping with a railway strike or coal dispute. Owing to the vigilant efficiency of the Port Sanitary Authorities and their officers, with the assistance given under the scheme devised, we have, as you know, almost completely escaped the risks against which it was designed. I have been surprised that this item has not been picked out as one of those portions of expenditure for which I am styled 'a squander-maniac,' because in the absence of an epidemic the kind of critic who goes in for these terminological fireworks can see nothing of a definite kind on which the money was expended. The fact, of course, that this trifling insurance has enabled us to escape disasters the consequences of which would have been hundreds of times more costly than the insurance itself is not the sort of consideration which appeals to the critic whose pabulum is head-lines."

Maternity and Child Welfare Work.

As another illustration of the reasonable expending of money he brought forward Maternity and Child Welfare work, saying that throughout the country it was costing a good deal of money and that in some cases the country was not getting the return which should have followed on the better training provided. "Therefore," said Dr. Addison, "I arranged for grants at about £20 a head for special training-classes for nurses, health-visitors and others, and added two or three expert medical officers centrally to supervise the work, as it was quite evident that the staff available could not physically compete with the amount required. The expenditure was a few thousand pounds. and, although I do not put it higher than being an important contributory cause to the recent striking improvement in the child-welfare statistics, it is one of the few new facts in the situation the importance of which cannot be ignored. You may be interested to know that the recent vote by Parliament to cover a week's loss owing to a railway strike is seven years the total expenditure in England and Wales out of the Exchequer of the whole of our Maternity and Child Welfare services; that the ten millions proposed to be given in aid of miners' wages will represent about nine years of our total Maternity and Child Welfare Exchequer contributions. . . . If it comes to a contest as to which expenditure is the more important to maintain, I tell you frankly that I shall place the interest of British babies before the building of barracks in Bagdad, and that a thousand maternity beds in decent houses for the use of women, who are now living in wretched slums, are of more value, as they are of less cost, than one giant gas-bag of doubtful utility."

The Vision of Opportunities.

After referring to the necessity for commencing the work in preventive medicine of the Ministry of Health by tackling the housing problem, he said that it would be easy to indicate a number of directions in which developments would be certain to arise in connexion with improved preventive and early remedial health services, such as would provide a substantial contribution towards diminishing the avoidable waste of life and strength to which we were still exposed. These things, he said, need cause no violent dislocation of business or great expenditure. There would be phases of advance and reaction, but the lessons of the War would not be forgotten, and they could only properly be utilised if they were supported by an instructed and considered professional opinion. "It is the purpose of the Federation to aid in furnishing that essential service, and it is evidence of a vigorous spirit to have a vision of the greater proved guilty of the charges, and the Council has directed the Registrar to erase from the Dentists Register the name George Ormiston.

Yearly Tables and Inspection of Final Examinations.

Dr. NORMAN WALKER (chairman of the Examination Committee) presented the report of the Examination Committee on the Yearly Tables and on the Inspection of Examinations. The Council's Committee state that in accordance with their recommendation adopted by the General Council on June 2nd, 1920, the annual tables showing for 1920 the results of examinations for qualifications primarily admitting to the Medical Register have not been printed. The following analyses of those which concern the Committee have been prepared as usual.

Of the 23 bodies granting primary qualifications, it will be seen that the returns for 1920 are complete so far as they go. The table concerned with higher qualifications calls for no special comment by the Committee. The table dealing with exemptions shows that these are again exceptionally numerous. As before, many of them are directly or indirectly due to the war; others to an increasing readiness to accept the examinations of other bodies.

The inspection of the final examinations is not yet completed. That in medicine is almost finished, but there are still seven bodies to be inspected in surgery and eight in midwifery. It is highly desirable that all these should be completed before November in time for consideration at the autumn session of the Council.

* At these examinations Medicine, Surgery, and Midwifery must be passed at one time.
† Medicine, Surgery, and Midwifery must be passed at one time, except in case of certain old students.
§ Medicine, Surgery, and Midwifery must be entered for at one time.

On June 2nd, 1920, the General Medical Council, by resolution, adopted the following recommendation of the Examination Committee:—

"That the licensing bodies which have not hitherto supplied in their annual return information as to whether they do or do not examine in operative surgery, ophthalmology, and mental disease, be asked to do so in future." (Minutes, 1920, p. 21.)

This resolution was communicated by the Registrar to the bodies concerned. As a result, the information given respecting the examinations held during 1920 is much more complete than that obtained regarding those held in 1919, as the following comparative table will show:—

	1919	1920
Operative Surgery:—		
Bodies giving passes and rejections	4	8
,, stating that it is included under Surgery	3	6
,, ,, that there is no special examination	—	7
,, ,, that there is no examination	—	2
,, not alluding to the subject	16	—
Ophthalmic Surgery or Ophthalmology:—		
Bodies giving passes and rejections	3	9
,, stating that it is included under Surgery	3	3
,, ,, that there is no special examination	1	9
,, ,, that there is no examination	—	2
,, not alluding to the subject	16	—
Mental Diseases:—		
Bodies giving passes and rejections	8	10
,, stating that it is included under Medicine	5	6
,, ,, that it is included under Surgery	—	1
,, ,, that there is no special examination	1	4
,, ,, that there is no examination in the subject	—	2
,, not alluding to the subject	9	—

Appointment of Branch Councils.

The following Branch Councils were appointed:—

Education Committee.—England: Sir F. Champneys, Dr. Howden, Sir Norman Moore; *Scotland:* Dr. Adams, Dr. Russell, Dr. N. Walker: *Ireland:* Sir Arthur Chance, Dr. Coffey, Sir John Moore.

Examination Committee.—England: Sir G. Barling, Dr. Caton, Dr. Macdonald; *Scotland:* Dr. Adams, Dr. Russell, Dr. N. Walker; *Ireland:* Sir Arthur Chance, Dr. Coffey, Sir John Moore.

Public Health Committee.—England: Dr. Dean, Sir G. Newman, Sir T. Jenner Verrall; *Scotland:* Dr. Matthew Hay, Mr. Littlejohn, Dr. McVail; *Ireland:* Sir E. Coey Bigger, Dr. Magennis, Sir John Moore.

The Council then adjourned.

THE Gloucestershire Scheme for the Extension of Medical Services, which was formally approved by the Ministry of Health in April, 1920, has been steadily coming into effective operation during the past month. Out-stations are now, or will shortly be, available in the areas of the Bristol Hospital, the Cheltenham General Hospital, and the Gloucestershire Royal Infirmary, and a circular letter as been issued by Dr. J. Middleton Martin, executive medical officer, to the medical officers in charge of the stations. The scheme deals with school children, tuberculosis, venereal disease, ex-Service men referred by pensions Committees, mothers and infants under the maternity and child welfare scheme, and other groups of patients by agreement.

THE FEDERATION OF MEDICAL AND ALLIED SOCIETIES.

THE annual dinner of the Federation of Medical and Allied Societies was held on May 26th at the Café Royal, London, Sir BERKELEY MOYNIHAN, the President of the Federation, being in the chair. The special guests of the evening were Dr. Christopher Addison, the late Minister of Health, and his successor, Sir Alfred Mond.

The loyal toast having been drunk, Sir BERKELEY MOYNIHAN proposed the health of Dr. Christopher Addison, the first Minister of Health. In eloquent terms he commended Dr. Addison's scientific equipment, sympathetic attitude towards medicine, and dignity under ill-informed criticism.

Dr. ADDISON thanked the Federation for the warm reception of the words from the chairman, and said that he especially valued the opinion of a body whose "aim is wide and public spirited, and marks a thoroughly wise departure from the usual purposes of professional associations. It is to promote in the medical profession the means whereby societies and associations of widely different aims from the professional or technical point of view may come together to consider not their own interests only, but in what manner they can work together for the public good, how the work of central or local governmental authorities affects the work of the medical profession and how it may best be guided and helped."

The Community of Medical Interests.

Dr. Addison then pointed out that the medical profession is not simply a body of trained men with work and interests bounded by a professional ring fence. If there was one lesson of the war, he thought, more manifest than another (though there were signs that it is being forgotten) it is that, in the language of the Scriptures, "we are members one of another." The strength or weakness of one class must be the strength or weakness of the rest, to be revealed in the time of stress, and conversely the progress and prosperity of any one class could not be promoted at the expense of the rest of the community, but would be conditioned by their progress and prosperity. He continued:—"The Federation seeks to foster in the profession a lively interest in public questions, and is confronted with peculiar difficulties, for the absorbing nature of medical practice leads to a detachment from public issues, making it difficult for medical men to appreciate the task of those who are associated with the work of government and its many-sided complications. Therefore it is hard for medical men to provide in considered and collective form the assistance which they are fitted to render to public authority. But society will seek more and more to enlist the aid of those who can help it to promote the physical well-being of its citizens—for the strength of the State is measured by the capacity of its individual members—and you all know how great is that mass of avoidable disability. In the early stages of the Ministry of Health its dominant purpose was necessarily the development of preventive agencies, primarily with the authority of the State, though the executive agents must, for the most part, be members of the medical or closely allied professions. We had and we have to take long views and be willing to create agencies and set work going that must take time to develop and to achieve results. Opportunist spectacular performances are not the function of a Ministry of Health. If they were to be, they would destroy any chance of achievement of its great and governing purposes."

Port Sanitary Work during the War.

Dr. Addison illustrated his meaning by pointing out that when the Ministry was established improved organisation of sanitary work at ports with suitable expert aid and laboratory equipment was arranged, so that the country should escape the various pestilences let loose by the war. "For this purpose," he said, "I inaugurated a system of assistance to Port Sanitary Authorities which they both needed and thoroughly deserved, whereby additional assistance of a suitable kind was available where required. So far as cost is concerned, the total of this effort is represented by a sum of £65,000 in this year's Estimates. It is a small figure compared with the millions people talk about when we are coping with a railway strike or coal dispute. Owing to the vigilant efficiency of the Port Sanitary Authorities and their officers, with the assistance given under the scheme devised, we have, as you know, almost completely escaped the risks against which it was designed. I have been surprised that this item has not been picked out as one of those portions of expenditure for which I am styled 'a squander-maniac,' because in the absence of an epidemic the kind of critic who goes in for these terminological fire-works can see nothing of a definite kind on which the money was expended. The fact, of course, that this trifling insurance has enabled us to escape disasters the consequences of which would have been hundreds of times more costly than the insurance itself is not the sort of consideration which appeals to the critic whose pabulum is head-lines."

Maternity and Child Welfare Work.

As another illustration of the reasonable expending of money he brought forward Maternity and Child Welfare work, saying that throughout the country it was costing a good deal of money and that in some cases the country was not getting the return which should have followed on the better training provided. "Therefore," said Dr. Addison, "I arranged for grants at about £20 a head for special training-classes for nurses, health-visitors and others, and added two or three expert medical officers centrally to supervise the work, as it was quite evident that the staff available could not physically compete with the amount required. The expenditure was a few thousand pounds, and, although I do not put it higher than being an important contributory cause to the recent striking improvement in the child-welfare statistics, it is one of the few new facts in the situation the importance of which cannot be ignored. You may be interested to know that the recent vote by Parliament to cover a week's loss owing to a railway strike is seven years the total expenditure in England and Wales out of the Exchequer of the whole of our Maternity and Child Welfare services; that the ten millions proposed to be given in aid of miners' wages will represent about nine years of our total Maternity and Child Welfare Exchequer contributions. . . . If it comes to a contest as to which expenditure is the more important to maintain, I tell you frankly that I shall place the interest of British babies before the building of barracks in Bagdad, and that a thousand maternity beds in decent houses for the use of women, who are now living in wretched slums, are of more value, as they are of less cost, than one giant gas-bag of doubtful utility."

The Vision of Opportunities.

After referring to the necessity for commencing the work in preventive medicine of the Ministry of Health by tackling the housing problem, he said that it would be easy to indicate a number of directions in which developments would be certain to arise in connexion with improved preventive and early remedial health services, such as would provide a substantial contribution towards diminishing the avoidable waste of life and strength to which we were still exposed. These things, he said, need cause no violent dislocation of business or great expenditure. There would be phases of advance and reaction, but the lessons of the War would not be forgotten, and they could only properly be utilised if they were supported by an instructed and considered professional opinion. "It is the purpose of the Federation to aid in furnishing that essential service, and it is evidence of a vigorous spirit to have a vision of the greater opportunities for public and professional service which the coming years would certainly offer."

Sir Malcolm Morris then proposed the health of Sir Alfred Mond, the Minister of Health, in a speech in the course of which he described the origin of the Federation and its constructive policy.

Sir Alfred Mond, in reply, said that his friend and predecessor in office, Dr. Addison, had two advantages over him:—First, as a medical man himself, he could command and obtain medical assistance from personal friends; secondly, he started the work of the Department at a time when the national purse was popularly supposed to be bottomless, whereas at the present moment rigorous economy was necessary. Sir Alfred Mond pointed out, however, that small economies which resulted in large expenses were not businesslike propositions, and that his aim would be to do a few things thoroughly, rather than spread the financial resources of the Ministry over a large number of services. Speaking as a layman, though head of the Ministry of Health, he ventured to point out that doctors' work was so absorbing that they were apt to look at public affairs in the wrong perspective. They could hardly help thinking of the nation in terms of the sick, whereas the majority of the public was perfectly healthy. He humorously commended the habit of doctors to take regular recreation on the golf-course, saying that such a habit was very good for doctors quite apart from any health question, as it compelled them to become acquainted with lay views and helped them to understand how medical affairs were regarded by a deeply interested public. Sir Alfred Mond then pointed out that the medical profession possessed most powerful influence in moulding opinion, but they must develop unanimity and decision. He concluded by saying that he should always welcome from the Federation all the assistance which they could give him in the shape of considered and corporate views on questions affecting the professions of medicine and pharmacy and nursing.

The toast of "Prosperity to the Federation" was proposed by Lieutenant-Colonel F. E. Fremantle, M.P., who said that he spoke as, in a sense, the first baby of the Federation, inasmuch as he believed that he was the first Member of Parliament in support of whose candidature the Federation had supplied speakers and assistance. He congratulated the Federation on the work that it had done and the ideals which it had placed before it. Speaking as a loyal member of the British Medical Association, he asserted that the work of the Federation could not be done by the Association.

Dr. Arthur Latham, replying for the Federation, thanked those present for their sympathy and asked for their support. He said the Federation was a federating force for the purpose of focusing the knowledge possessed by all grades of health workers to the advantage of the community. They regarded the manufacture of health as the key industry of the country, and they differed from all other societies in that the patient was their prime consideration—the potential patient, who represented the preventive side of their work, and the actual patient, who would benefit by their efforts in remedial or happily curative measures against disease. They wished to enlighten public opinion in health matters, and he called attention to the fact that the public conscience was awakening to the value of the health worker, as was shown by the number of medical men in the House of Commons, the peerage conferred on Lord Dawson of Penn, and the appointment of Sir Clifford Allbutt to the Privy Council. They were jealous of the interests of their members, but they hoped by suasion rather than dictation to show the public and the leaders of the public that if they were to have an efficient band of health workers they must make such a career an attractive one. Behind their work was a good idea. Individuals might delay the fructification of a good idea, but they could not kill it.

Already they represented 18,000 doctors and 90,000 health workers, and he was confident that their sphere of influence would rapidly increase.

Among those present at the dinner were Lord Dawson of Penn; Sir Arthur Stanley (President, British Hospitals Association): Sir George Newman (Chief Medical Officer, Ministry of Health); Sir H. Kingsley Wood, M.P. (Parliamentary Private Secretary, Ministry of Health): Sir Arthur Robinson (Permanent Secretary, Ministry of Health); *Sir Thomas Neill (Chairman of Council for* National Health Insurance, Ministry of Health); Mr. A. C. Thompson (Chairman of National Conference of Industrial Approved Societies); Viscount Knutsford (British Hospitals Association); Lord Queenborough: Dr. Nathan Raw, M.P.; Dr. Donald Murray, M.P.; Sir Philip Magnus, M.P.: Dr. G. de Bec Turtle (President, Harveian Society of London); Dr. A. G. Buchanan, (President, Chelsea Clinical Society); Dr. F. J. McCann (President, West London Medico-Chirurgical Society); Dr. T. A. Goodfellow (President, Manchester Medical Society); Dr. J. Forsyth Craig (President, Birmingham and District Medical Practitioners Union); Dr. Godfrey Carter (President, Sheffield Medico-Chirurgical Society); Lieutenant-Colonel Hugh Stott (President, Brighton and Sussex Medico-Chirurgical Society); Dr. J. E. Gemmell (President, Liverpool Medical Institution); Dr. J. F. Murton (President, Nottingham Medico-Chirurgical Society): Miss Olga Nethersole (Hon. Secretary, The People's League of Health); Mr. E. T. Neathercoat (President, Pharmaceutical Society of Great Britain); Sir William Glyn-Jones (Secretary, Pharmaceutical Society of Great Britain); Mr. Philip Rowsell, J.P. (Pharmaceutical Society of Great Britain); Dr. Farquhar Buzzard (Royal Society of Medicine); Dr. J. F. Gordon Dill (Royal Society of Medicine); Sir John MacAlister (Secretary, Royal Society of Medicine); Dr. Jane Walker and Lady Barrett, M.D. (Medical Women's Federation); Sir StClair Thomson; Mr. Ernest Clarke; Dr. Charles Buttar (Harveian Society); Sir Bruce Bruce-Porter; Mr. E. B. Turner (National Council for Combating Venereal Diseases); Major R. Worth, Sir Maurice Craig, and Dr. E. S. Pasmore (Medico-Psychological Association of Great Britain and Ireland); Miss E. C. Barton (Poor-law Infirmary Matrons Association): Dr. and Mrs. Remington Hobbs (Infirmary Medical Superintendents Society); Sir Sydney Beauchamp: Sir Squire Sprigge; Sir Crisp English; Colonel A. S. Woodwark; Mr. P. L. Lockhart-Mummery; Dr. H. J. Cardale and Dr. R. J. Farman (Association of Panel Committees); Dr. F. Hernaman-Johnson (British Association of Radiology and Physiotherapy); Mr. C. F. Rilot (British Dental Association); Mr. Montagu Hopson (President, British Dental Association); Mr. Robert Lindsay (Dental Secretary, British Dental Association); Major C. Thomson, M.D. (West Kent Medico-Chirurgical Society); Sir Ronald Ross (British Science Guild); Dr. E. H. M. Stancomb (Southampton Medical Parliamentary Committee); Miss H. L. Pearse and Miss Lord (National Union of Trained Nurses); Miss Sheriff-MacGregor (College of Nursing); Dr. H. Wansey Bayly (Society for the Prevention of Venereal Disease); Mrs. Greenwood, Miss Armitage, Miss de Chaumont, Miss Hoskins, Miss Jarvis, and Miss Whitbread (Women Health Visitors Association); Sir Ernest Hodder-Williams; Dr. David Lawson; Dr. G. E. Haslip; and Dr. Howard Mummery (General Secretary, 5, Vere-street. W. 1.)

AUSTRALIA.

(From our own Correspondent.)

Public Health Association.

The Brisbane Medical Congress last year decided, through some members interested in public health, to form a Public Health Association of Australia. The underlying idea is that the laity should be encouraged and educated to take an interest in matters of public health apart from politics. A provisional committee was appointed to complete preliminaries. A meeting was held in Melbourne Town Hall on April 11th to inaugurate the movement. Office-bearers are already appointed, and although the aim of the Association is stated to be "free from departmental connexions," almost all the office-bearers are departmental medical officers. The President is Dr. J. H. L. Cumpston, Director of the Federal Health Department. Provision is made for all classes of members, but the lowest subscription is to be £1 per annum. It is proposed, if funds permit, to publish a periodical devoted to questions of public health. His Excellency the Governor of

Victoria and the Countess of Stradbroke attended the meeting.

Death of Dr. C. J. Tozer.

The trial of Mrs. Mort, charged with the murder of Dr. C. J. Tozer, under circumstances already described, came before the Chief Justice and a jury in Sydney on April 6th. The accused was still in a weak state, and required special attention throughout the proceedings. Medical evidence was given that Mrs. Mort had always been of neurotic temperament, and evidence was also brought that she had applied for employment as a film artist, and had been sent home by the manager suffering from delusions that men were following her. Dr. R. Lee Brown, Government medical officer at Long Bay Penitentiary, where Mrs. Mort was detained, gave evidence that he had seen her daily during her detention and observed no signs of insanity. The jury decided that the accused was insane when she committed the act, and she was ordered to be detained during the Governor's pleasure.

Small-pox.

A suspicious case of illness in the Melbourne Hospital was reported to the health authorities as probably small-pox. The patient was a coloured fireman from the s.s. *Gracchus*. The Health Department at first pronounced the disease to be chicken-pox, but subsequently regarded it as small-pox. Six cases from the same steamer have since been reported from Sydney, whither the *Gracchus* had proceeded. She called at Fremantle and Adelaide, but no shore cases have yet been registered.

May 4th.

DANGEROUS DRUGS ACT:

REVISED REGULATIONS.

THE Committee appointed last March by the Home Secretary to consider the objections raised to the draft regulations issued under the Dangerous Drugs Act, 1920, has issued a report, dated May 12th, as a Parliamentary White Paper [*Cmd. 1307.* Price 3*d.*], which may be obtained from H.M. Stationery Office. The personnel of this Committee was as follows: Mr. Chester Jones (chairman), Sir Malcolm Delevingne, K.C.B., Captain W. E. Elliot, *M.C.*, M.P., Major A. C. Farquharson, M.D., M.P., Mr. Gerald A. France, M.P., Sir Beville Stanier, Bart., M.P., and Mr. W. J. U. Woolcock, *C.B.E.*, M.P., with Mr. A. H. Anderson of the Home Office as Secretary.

After a closely reasoned argument, which we summarise elsewhere, the Committee presents the regulations in an amended form, which will, it trusts, go a long way to prevent the increase of the drug habit without avoidable inconvenience to the medical or pharmaceutical profession or to the public.

TEXT OF THE REGULATIONS.

1. *Application.*—The drugs to which these Regulations apply are morphine, cocaine, ecgonine, and diamorphine (commonly known as heroin), and their respective salts, and medicinal opium, and any preparation, admixture, extract or other substance containing not less than one-fifth per cent. of morphine or one-tenth per cent. of cocaine, ecgonine or diamorphine.

For the purpose of the foregoing provision, the percentage in the case of morphine shall be calculated as in respect of anhydrous morphine.

2. *Manufacture.*—No person shall manufacture or carry on any process in the manufacture of morphine, cocaine, ecgonine or diamorphine, or their respective salts or medicinal opium—

(*a*) unless he is licensed by the Secretary of State or is authorised by these Regulations or by any authority granted by the Secretary of State to do so,

(*b*) except on premises licensed for the purpose by the Secretary of State,

(*c*) otherwise than in accordance with the terms and conditions of such licence or authority.

3. *Sale, Distribution and Possession.*—No person shall supply or procure or offer to supply or procure any of the drugs to or for any person whether in the United Kingdom or elsewhere or shall advertise any of the drugs for sale—

(*a*) unless he is licensed by the Secretary of State or is authorised by these Regulations or by any authority granted by the Secretary of State to supply the drug or unless he is licensed by the Secretary of State to import or export the drug or unless he is licensed or otherwise authorised to manufacture the drug or

(*b*) otherwise than in accordance with the terms and conditions of such licence or authority.

4. Except when the drugs are lawfully dispensed in pursuance of a prescription given by a duly qualified medical practitioner, registered dentist or registered veterinary surgeon, or are supplied by a duly qualified medical practitioner or registered veterinary surgeon who dispenses his own medicines, in accordance with the conditions hereinafter specified, no person shall supply or procure or offer to supply or procure any of the drugs to or for any person in the United Kingdom who is not licensed or otherwise authorised to be in possession of the drug nor to any person so licensed or authorised except in accordance with the terms and conditions of such licence or authority.

Provided that administration of the drugs by or under the direct personal supervision of a duly qualified medical practitioner, or by or under the direct personal supervision of a registered dentist in dental treatment, or by or under the direct personal supervision of a registered veterinary surgeon in the treatment of any animal, shall not be deemed to be supplying the drug within the meaning of this and the following Regulations.

5. A prescription for the supply of the drugs must comply with the following conditions:—

The prescription must be in writing, must be dated and signed by the medical practitioner, registered dentist or registered veterinary surgeon as the case may be, with his full name and address, and must specify the name and address of the person for whose use the prescription is given, and the total amount of the drug to be supplied on the prescription, except that in the case of prescriptions issued for national health insurance purposes on the form provided by the Insurance Committee the medical practitioner's address need not be marked on the prescription.

A prescription shall only be given by a registered dentist for the purposes of dental treatment and shall be marked "For local dental treatment only."

A prescription shall only be given by a registered veterinary surgeon for the purposes of treatment of animals and shall be marked "For animal treatment only."

The Secretary of State may prescribe and issue a form hereinafter referred to as the "official form" for use in giving prescriptions for the drugs, and in that case a prescription for any of the drugs shall only be given on an official form or in the case of prescriptions issued for national health insurance purposes on the form provided by the Insurance Committee, provided that in a case of emergency when the person giving the prescription has not the official form available, the prescription may be given without using the official form, but in that case shall be marked with the words "Official Form not available" or similar words.

A medical practitioner, registered dentist or registered veterinary surgeon shall not give any prescription for the supply of any of the drugs otherwise than in accordance with the foregoing conditions.

A medical practitioner who dispenses any medicines to which these Regulations apply shall enter particulars thereof in his day book or in the register hereinafter specified.

6. The following conditions shall be observed by persons dispensing prescriptions for the drugs:—

(*a*) If an official form is prescribed and issued by the Secretary of State in pursuance of the foregoing Regulation, a prescription for any of the drugs shall only be dispensed if the prescription is on one of those forms or on the form provided for national health insurance purposes by the Insurance Committee, or in the case of an emergency prescription given under the conditions specified in the foregoing Regulation, if the person dispensing the prescription is acquainted with the signature of the medical practitioner, registered dentist, or registered veterinary surgeon by whom the prescription purports to be given, or is acquainted with the person for whose use the prescription is given and has no reason to suppose that the prescription is not genuine;

(*b*) the drugs shall not be supplied more than once on the same prescription: Provided that, if the prescription so directs, the drugs may be supplied on more than one but not exceeding three occasions, as directed in the prescription, at intervals to be specified in the prescription;

(c) the prescription shall be marked with the date on which it is dispensed, and shall be retained by the person, firm, or body corporate by whom the prescription is dispensed, and (unless issued for national health insurance purposes on the form provided by the Insurance Committee) shall be kept on the premises where it is dispensed and shall be available for inspection.

7. No person shall be in possession of any of the drugs unless—

(a) he is licensed to import or export the drug, or

(b) he is licensed or otherwise authorised to manufacture or supply the drug, or

(c) he is otherwise licensed by the Secretary of State or authorised by these Regulations or by any authority granted by the Secretary of State to be in possession of the drug, or

(d) he proves that the drug was supplied for his use by a duly qualified medical practitioner or registered veterinary surgeon or on and in accordance with such a prescription as aforesaid.

8. (i) No person shall supply any morphine, cocaine, ecgonine, diamorphine or their respective salts or any medicinal opium unless the package or bottle containing it is plainly marked with the amount of the drug in the package or bottle.

(ii) No person shall supply any preparation, admixture, extract, or other substance containing any of these last mentioned drugs and coming within these Regulations unless the package or bottle is plainly marked

(a) in the case of a powder, solution, or ointment, with the total amount thereof in the package or bottle and the percentage of the drug in the powder, solution, or ointment;

(b) in the case of tablets or other articles with the amount of the drug in each article and the number of articles in the package or bottle.

This Regulation shall not apply to any preparation dispensed by a duly qualified medical practitioner or on the prescription of a duly qualified medical practitioner.

9. Every person who supplies any of the drugs shall comply with the following provisions:—

(a) he shall enter or cause to be entered in a register kept for the sole purpose all supplies of the drug purchased or otherwise obtained by him and all dealings in the drug effected by him (including sales or supplies to persons outside the United Kingdom) in the form and containing the particulars shown in Schedule I. to these Regulations;

(b) separate registers or separate parts of the register shall be used for (a) cocaine and ecgonine and substances containing them, (b) morphine and substances containing it, (c) diamorphine and substances containing it, (d) medicinal opium; provided that with the approval of the Secretary of State separate registers may be kept for separate departments of a business;

(c) he shall make the entry with respect to any of the drugs purchased or otherwise obtained by him on the day on which the drug is received and with respect to any sale or supply by him of the drug on the day on which the transaction is effected; or where that is not reasonably convenient on the day following the day on which the drug is received or the transaction is effected;

(d) where he carries on business at more than one set of premises he shall keep a separate register or registers in respect of each set of premises;

(e) he shall keep the register or registers in some part of the premises to which it relates so that it shall at all times be available for inspection in accordance with the provisions of the Act;

(f) he shall not cancel, obliterate, or alter any entry in the register or make therein any entry which is untrue in any particular. Any mistake in an entry may be corrected by a marginal note or footnote giving the correct particulars and dated:

(g) he shall furnish to the Secretary of State or to any person authorised by any order of the Secretary of State for the purpose all information in regard to any purchases by him of the drugs, all stocks held by him of the drugs, and all transactions effected by him in the drugs as may be required by the Secretary of State for the purpose of seeing that the provisions of the Act are observed.

A duly qualified medical practitioner who records in a day book particulars of any of the drugs supplied by him to any patient, together with the name and address of the patient and date of the supply, may, in lieu of keeping the register required by this Regulation of drugs sold or supplied by him, enter separately for each of the drugs in a book to be kept for the purpose references under the appropriate dates to the records in the day book of any supply of the drug. A person lawfully keeping open shop for the retailing of poisons in accordance with the provisions of the Pharmacy Act, 1868, as amended by the Poisons and Pharmacy Act, 1908, may in lieu of keeping the register required by this Regulation of drugs sold or supplied by him enter separately for each of the drugs in a book to be kept for the purpose references under the appropriate dates to the entries in the "Poisons Book" or "Prescription Book" kept by him in pursuance of Section 17 of the Pharmacy Act, 1868, relating to any supply of the drugs. Provided that all such books shall at all times be available for inspection in accordance with the provisions of the Act.

10. Any person lawfully keeping open shop for the retailing of poisons in accordance with the provisions of the Pharmacy Act, 1868, as amended by the Poisons and Pharmacy Act, 1908, is hereby authorised—

(a) to manufacture at the shop in the ordinary course of his retail business any preparation, admixture, or extract of any of the drugs;

(b) to carry on at the shop the business of retailing, dispensing, or compounding the drugs, but subject always to the provisions of these Regulations.

In the event of any such person being convicted of an offence against the Act or of an offence under the enactments relating to the Customs as applied by the Act, the Secretary of State may by notice in the London, Edinburgh or Dublin Gazette withdraw the authorisation aforesaid, if, in the opinion of the Secretary of State, such person cannot properly be allowed to carry on the business of manufacturing or selling or distributing as the case may be, any such drug; provided that the Secretary of State shall, before withdrawing the authorisation in the case of any such person, consult the Council of the Pharmaceutical Society of Great Britain.

11. Any duly qualified medical practitioner, or any registered dentist, or any registered veterinary surgeon or any person employed or engaged in dispensing medicines at any public hospital or other public institution being a person duly registered under the Pharmacy Act, 1868, as amended by the Poisons and Pharmacy Act, 1908, or any person in charge of a laboratory for purposes of research or instruction attached to any University, University College, public hospital or other institution approved by the Secretary of State for the purpose, or any person appointed by a local authority with the approval of the Minister of Health as an analyst for the purposes of the Sale of Food and Drugs Acts, 1875 to 1907, is hereby authorised so far as is necessary for the practice of his profession or employment in such capacity to be in possession of and supply the drugs.

12. In the event of any person authorised by these Regulations or by any authority granted by the Secretary of State to manufacture, supply or be in possession of the drugs, or any of them, being convicted of any offence against the Act or of an offence under the enactments relating to the Customs as applied by the Act, the Secretary of State may by notice in the London, Edinburgh or Dublin Gazette withdraw the authorisation in respect of such person, if, in the opinion of the Secretary of State such person cannot properly be allowed to manufacture, supply or be in possession of any such drug.

13. No person shall deliver any of the drugs to any person not licensed or otherwise authorised to be in possession of the drugs who purports to be sent by or on behalf of a person so licensed or authorised unless such person produces an authority in writing, signed by the person so licensed or authorised, to receive the drug on his behalf and unless the person supplying the drug is satisfied that the authority is genuine. This Regulation shall not be deemed to apply to medicines dispensed in pursuance of the foregoing Regulations.

14. Any of the drugs in the order or disposition of any person shall be deemed to be in his possession.

15. In the case of a ship not carrying as part of her complement a duly qualified medical practitioner, the master of the ship shall be deemed to be a person authorised to be in possession of the drugs so far as is necessary to comply with the requirements of the Merchant Shipping Acts, and it shall also be lawful for him, subject to any conditions prescribed by the Secretary of State, to administer and supply the drugs to any member of the crew in accordance with instructions prepared or sanctioned by the Board of Trade. The keeping of a record of the use of the drugs in the official log in accordance with the provisions of the Merchant Shipping Acts shall be deemed to be compliance with the requirements of these Regulations as to the keeping of records.

16. The Secretary of State may exempt from the operation of these Regulations any hospital or other public institution subject to the observance of such conditions as he may by order prescribe.

17. These Regulations shall not apply in respect of the preparations named in Schedule II. to these Regulations, nor to any of the drugs when denatured in a manner approved by the Secretary of State. The Secretary of State may from time to time by order add any other preparation to the Schedule or remove any preparation from the Schedule.

18. In the application of these Regulations to Ireland :—

(a) A reference to the Poisons (Ireland) Act, 1870, the Pharmacy (Ireland) Act, 1875, and the Pharmacy (Ireland) Act, 1875, (Amendment) Act, 1890, shall be substituted for any reference to the Pharmacy Act, 1868, and

(b) A reference to the Pharmaceutical Society of Ireland shall be substituted for the reference to the Pharmaceutical Society of Great Britain.

Forms to be used by those Supplying Drugs.

Schedule I. gives the approved form of records as follows :—

(a) Record of { Morphine, &c.
Diamorphine (Heroin), &c.
Cocaine, &c.
Medicinal Opium. } Purchased or otherwise obtained.

Date on which supply received.	Name of person, body or firm from whom obtained.	Address of person, body or firm from whom obtained.	Amount obtained.	Form in which obtained.

(b) Record of { Morphine, &c.
Diamorphine (Heroin), &c.
Cocaine, &c.
Medicinal Opium. } Sold or supplied.

Date on which the transaction was effected.	Name of person, body or firm to whom sold or supplied.	Address of person, body or firm to whom sold or supplied.	Authority of person, body or firm to be in possession of the drug.	Amount sold or supplied.	Form in which sold or supplied.	When sale is on a prescription specify the ingredients of the prescription.

Exemption of Certain Familiar Remedies.

Certain familiar remedies containing narcotic drugs are exempt from the regulations under §17. These are given in a schedule as follows :—

Schedule II.—Cereoli Iodoformi et Morphinæ, B.P.C., Emp. Opii, B.P., 1898, Lin. Opii, B.P., Lin. Opii Ammon., B.P.C., Pasta Arsenicalis, B.P.C., Pil. Hydrarg. c. Opio, B.P.C., Pil. Ipecac. c. Scilla, B.P., Pil. Plumbi c. Opio, B.P., Pil. Digitalis et Opii Co., B.P.C., Pil. Hydrarg. c. Cret. et Opii, B.P.C., Pulv. Cretæ Aromat. c. Opio, B.P., Pulv. Ipecac. Co., B.P. (Dover's Powder), Pulv. Kino Co., B.P., Suppos. Plumbi Co., B.P., Tablettæ Plumbi c. Opio, B.P.C., Ung. Gallæ c. Opio, B.P. (Gall and Opium Ointment), Ung. Gallæ Co., B.P.C.

ROYAL SANITARY INSTITUTE.—A sessional meeting will be held on Thursday and Friday, June 9th and 10th. 1921, in the Guildhall, Gloucester, jointly with the West of England branch of the Society of Medical Officers of Health. On June 9th at 10 A.M. a discussion on Public Health Development in Gloucestershire will be opened by Dr. J. Middleton Martin. At 2.30 P.M. a visit will be paid to Cheltenham Corporation Refuse Destructor, Sewage and Water Works. On June 10th at 10 A.M. Major E. W. A. Carter, M.I.M.C.E., will open a discussion on the Collection and Disposal of House Refuse. Professor H. R. Kenwood will preside. Those proposing to attend the meetings should notify the Hon. Local Secretary, Dr. J. R. Bibby, 9, New Inn-lane, Gloucester, so that the necessary arrangements may be made.

Public Health Services.

The Allocation of Sanatorium Benefit Surplus.

THE Lancashire Insurance Committee has approved a recommendation by its finance committee as to the allocation of a sum of about £18,000 standing to its credit at the end of March. The finance committee recommended that £10,000 should at once be handed over to the county council for its tuberculosis scheme, and that the whole of the surplus should be applied in the same way as soon as its total can be ascertained. The Ministry of Health and the local committee do not see eye to eye as to the disposal of this surplus credited to the committee's sanatorium benefit fund. When the National Insurance Act was amended last year sanatorium benefit was abolished, and the Health Ministry was empowered to provide by regulation for the disposal of any such surpluses, provided that they were paid over to the Ministry itself, except when the Ministry might decide that part should go to the local county council. The local committee has taken its own course without waiting for the approval of the Ministry of Health. The local committee states its reasons in favour of the course it has adopted, and correspondence with the Ministry has taken place. So far the Ministry has not declared its intention to take the Lancashire surplus to its own uses, nor has it stated what part of the total surplus would remain for use in the county area. A conflict has thus arisen as to the disposal of the surplus funds.

Paying Patients at Poor-law Hospitals.

Mr. R. A. Leach, clerk to the Rochdale Board of Guardians, read a paper at the Northern Poor-law Conference, recently held at Keswick, on the admission to Poor-law hospitals of private patients. He stated that had the suggestion been made before the war the reply would have been "No." Having regard to the fact that during the war hundreds of thousands of British sick and wounded were maintained, treated, cared for, and healed in the Poor-law hospitals, why should not these hospitals, if empty beds are available, be used for civilians other than of the Poor-law class? Several boards of guardians, especially in Lancashire, opened their hospitals to such patients. If the hospitals are so opened it was imperative that the guardians should safeguard the rights of the poor, and above all, it behoved the guardians not to allow themselves to be fettered with rules and regulations that might impair the guidance, government, and control of their hospitals; that is, they should not do anything or consent to anything which was calculated to injure them as the statutory authority for the relief of destitution. The sick poor should never come under any risk of hustle with the better-off classes to obtain admission to the hospitals. After discussion the Conference passed a resolution that when there were surplus beds immediate measures should be adopted to take advantage of the changed attitude of the Ministry of Health to throw open this vacant accommodation to non-Poor-law cases, having due regard to the position of local voluntary hospitals.

SCHOOL MEDICAL INSPECTION.

Shrewsbury.

In his report[1] on school medical inspection for 1919 at Shrewsbury Dr. James Fenton, medical officer of health and school medical officer, states that very little had been done during 1916, 1917, and 1918, but that the work returned to normal from the beginning of 1919. The number of children on the registers was 4494, and the number examined in the code groups was 1172, time not allowing of a complete examination in the case of the elder children. The most common defect requiring treatment was uncleanliness of the head (22·9 per cent.), and next to this dental disease (9·9 per cent.). Nutrition was satisfactory, only 11 children among those in the code groups (0·94 per cent.) needing attention. There were seven cases of organic heart disease, but only one of definite pulmonary tuberculosis. Dr. Fenton considers that, on the whole, children appear to be better nourished than they were before the war, and has "come to the definite conclusion that there is less evidence of thriftlessness and drunkenness amongst parents." On the other hand, the important but disquieting statement is made that "the inspections show that each year there is a marked falling off in vaccination compared with the previous one, and the time appears to be rapidly approaching when there will be very few children in the town protected against small-pox." Among the 12-year old children, 6·1 per cent.; among those of 8 years, 31·0 per cent.; and of the 5-year old children, 148, or 41·2 per cent., were found to be unvaccinated. It must be acknowledged that the responsibility for this condition cannot be attributed only to the ignorance of the parents. An important advance has been made in the treatment of ringworm of the scalp. During 1915, 77 children lost 11,125 attendances from this cause, causing a total loss of grant amounting to £48 12*s*. At the beginning of 1916 the Education Committee adopted the X ray treatment, and decided to pay the whole of the expense, the children having to be conveyed to Birmingham for the purpose; 136 cases have been treated with entire success during these four years. There has been a saving of over 10,000 school attendances per annum, and a gain of something like £45 per annum in the Government grant. There are now only two children in the whole town absent from school on this account. There has also been an improvement in the cleanliness of the children, owing to the support given by the magistrates and the press, though 22·86 per cent. of those examined in the code groups were found to need treatment.

---

[1] Annual Report of School Medical Officer for 1919.

Cardiff.

Until November, 1919, the work of school medical inspection[2] at Cardiff was carried on under considerable difficulties on account of disorganisation of staff and arrangements due to war conditions. The intermediate group of children (8 years of age) could not be examined, but all arrears were overtaken and the entrants and leavers completed—these numbered 8077; and in addition 1248 children were brought forward as special cases. In the code groups systematically inspected, defective vision (462) and squint (68) combined to form the most numerous group requiring treatment; and after them enlarged tonsils (314), or adenoids (104), or both of these conditions together (89). Organic heart disease was diagnosed in 18 children, of whom 9 were recommended for treatment, and 9 to be kept under observation. Not a single case of definite pulmonary tuberculosis was found during the routine examinations; 6 cases were "suspected," of which 3 were referred for treatment. It is stated that "cases of nose, throat, and ear defects, defective vision, and minor ailments, if treatment is not otherwise procurable, are referred for treatment at the school clinic," where, however, the facilities provided are at present inadequate, and "it is feared that in consequence many have to go without treatment." It is also observed that "there are many cases for the treatment of which no special provision is made, and parents are in such cases recommended to seek the advice of their own doctor." No mention is made of any available hospital or dispensary treatment. As regards care of the teeth, Dr. Edward Walford, medical officer of health for the city and school medical officer, who presents this report, states that "at present the dental arrangements provide only for the inspection of children between the ages of 6 and 8 years, and for the treatment of the children in that group requiring it, and belonging to families whose weekly income does not exceed £4." Everyone will agree with his remarks that "these arrangements are extremely inadequate," and that "the school dental service urgently requires development and expansion, and an additional dentist (whole time) should be appointed." About 5 per cent. of the children inspected suffer from enlarged tonsils or adenoids, and require treatment by an aural surgeon. At present operative treatment is carried out on one half-day a week. This is not enough, and a large number of cases are awaiting treatment. An aural surgeon should attend on two half-days a week, and operations should be performed in the afternoon, the patients being detained overnight in a recovery room, of course under care of a nurse, and handed over to their parents next day. With regard to "minor ailments"—ringworm, scabies, skin diseases, otorrhœa, &c., which are a cause of considerable non-attendance at school, with consequent loss of grant, the arrangements appear to be very unsatisfactory. "No child attends at the clinic for treatment more often than once a week, consequently the treatment devolves to a great extent upon parents, and has to be continued in many instances over a long period, instead of being regularly and carefully carried out by school nurses under the supervision of medical officers." There can be no question that there is urgent necessity, as Dr. Walford points out, for a school clinic to be open daily for, say, two hours, with school nurses in attendance, in order that minor ailments may be treated regularly and thoroughly. The X ray treatment should also be provided for ringworm. There were 92 cases of ringworm of the head during the year under report, 83 of which were "specials," but it is not stated how long these children were absent from school on this account—i.e., how long they were deprived of education through want of effective treatment. The provision of a suitably constructed and equipped building as a school clinic appears to be a pressing need at Cardiff, the facilities for treatment at present being "inadequate and altogether unsuitable." It appears that one room only is available for operations—eye treatment, dental treatment, and for minor ailments. The five rooms at the City Hall at present available are obviously not nearly sufficient. As the city of Cardiff ranks first in the Principality in regard to population and prosperity, it may be confidently anticipated that adequate arrangements will be made by the civic authorities to enable this necessary work to be satisfactorily dealt with.

VITAL STATISTICS OF LONDON DURING APRIL, 1921.

IN the accompanying table will be found summarised statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the ten diseases notified in the table was equal to an annual rate of 8·7 per 1000 of the population, estimated at 4,531,971 persons in the middle of 1920; in the three preceding months the rates had been 10·6, 10·2, and 9·7 per 1000. Among the metropolitan boroughs the lowest rates from these diseases were recorded in Paddington, Chelsea, the City of Westminster, St. Marylebone, Hampstead, and the City of London; and the highest in Hackney, Finsbury, Bethnal Green, Stepney, and Woolwich. The prevalence of enteric fever was about equal to that in the preceding month; of the 14 cases notified during the four weeks ended April 30th, 2 cases belonged to each of the boroughs of Paddington, Hampstead, Greenwich, and Lewisham. There were 10 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 11·9 and 10 at the end of the three preceding months; the weekly admissions averaged 2, against 3, 2, and 3 in the three preceding months. The case of small-pox occurring during the month was notified from the borough of Holborn. The prevalence of scarlet fever was 10 per cent. less than in the preceding month: this disease was proportionally most prevalent in Hammersmith, Hackney, Bethnal Green, Stepney, Bermondsey, and Woolwich. The Metropolitan Asylums Hospitals contained 3217 scarlet fever patients at the end of the month, against 2618, 2766, and 2652 at the end of the three preceding months; the weekly admissions averaged 411, against 489, 461, and 469 in the three preceding

* Including membranous croup.

months. Diphtheria also was somewhat less prevalent—about 12 per cent.—than in March; the greatest proportional prevalence of this disease was recorded in Islington, Hackney, Finsbury, Shoreditch, Bethnal Green, and Deptford. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 2648, 2766, and 2652 at the end of the three preceding months, numbered 2129 at the end of April; the weekly admissions averaged 261, against 319, 333, and 290 in the three preceding months. Erysipelas was proportionally most prevalent in Fulham, Chelsea, Stoke Newington, Holborn, the City of London, and Bethnal Green. The 2 cases of poliomyelitis belonged to Wandsworth. The prevalence of encephalitis lethargica showed a marked decrease since the beginning of the year, 77 cases having been notified in January, 56 in February, 24 in March (five weeks), and 14 in April; of these latter, 3 belonged to Southwark, and 2 to Hampstead. Twelve cases of cerebro-spinal fever were notified during the month, against 11, 17, and 14 in the three preceding months; of these 3 were notified from Finsbury, 2 from Hammersmith, 2 from Islington, and 2 from Lambeth. The 30 cases of puerperal fever included 5 in Stepney and 3 in Fulham.

The mortality statistics in the table relate to the deaths of civilians actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ended April 30th the deaths of 4387 London residents were registered, equal to an annual rate of 12·6 per 1000; in the three preceding months the rates had been 12·5, 14·0, and 13·6 per 1000. The death-rates ranged from 9·6 in Wandsworth, 10·5 in Lewisham, 10·8 in the City of London, 11·0 in Hammersmith and in Hampstead, to 15·5 in Finsbury, 15·7 in Southwark, 16·4 in Chelsea, 17·1 in St. Marylebone and in Holborn, and 17·9 in Shoreditch. The 4387 deaths from all causes included 242 which were referred to the principal infectious diseases; of these 2 resulted from enteric fever, 31 from measles, 20 from scarlet fever, 41 from whooping-cough, 93 from diphtheria, and 52 from diarrhœa and enteritis among children under two years of age. No death from any of these diseases was recorded in the City of London. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in Paddington, Hammersmith, Fulham, Chelsea, Southwark, Wandsworth, and Greenwich; and the highest in Hampstead, Islington, Stoke Newington, Finsbury, Shoreditch, Bethnal Green, and Bermondsey. The 2 fatal cases of enteric fever were 4 fewer than the average in the corresponding period of the five preceding years. The 31 deaths from measles were about one-sixth of the average; of these 10 belonged to Shoreditch, 8 to Islington, and 4 to Lewisham. The 20 fatal cases of scarlet fever exceeded the average by 7; of these, 3 belonged to Lambeth, 2 to Kensington, 2 to Bethnal Green, and 2 to Stepney. The 41 deaths from whooping-cough were less than a third of the average number; of these, 6 belonged to Islington, 5 to Camberwell, 4 to Shoreditch, and 3 to each of the boroughs of St. Pancras, Battersea, and Lewisham. The 93 fatal cases of diphtheria were 39 in excess of the average; the greatest proportional mortality from this disease occurred in St. Marylebone, Stoke Newington, Hackney, Finsbury, Shoreditch, Bethnal Green, and Bermondsey. The 52 deaths from infantile diarrhœa were 4 below the average; the greatest proportional mortality from this disease occurred in Paddington, Stoke Newington, Holborn, Bethnal Green, Bermondsey, and Deptford. In conclusion, it may be stated that the aggregate mortality in London during April from these principal infectious diseases was 47 per cent. below the average in the corresponding period of the five preceding years.

URBAN VITAL STATISTICS.

(Week ended May 21st, 1921.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate population estimated at 18¼ million persons, the annual rate of mortality, which had been 12·5, 12·4, and 12·5 in the three preceding weeks, fell to 11·3 per 1000. In London, with a population of 4½ million persons, the annual rate was 10·7, or 0·9 per 1000 below that recorded in the previous week, while among the remaining towns the rates ranged from 3·9 in Swindon, 6·2 in East Ham, and 6·4 in Hornsey to 18·9 in St. Helens, 20·7 in West Hartlepool, and 21·1 in Oldham. The principal epidemic diseases caused 213 deaths, which corresponded to an annual rate of 0·6 per 1000, and comprised 63 from infantile diarrhœa, 48 from whooping cough, 44 from diphtheria, 43 from measles, 11 from scarlet fever, and 4 from enteric fever. Measles caused a death-rate of 1·1 in Portsmouth, 1·8 in South Shields, 2·5 in Exeter, and 2·7 in Barrow-in-Furness, and whooping cough of 1·3 in Warrington and in Preston. There were 3209 cases of scarlet fever and 2215 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 3238 and 2281 respectively at the end of the previous week. During the week ended May 14th, 5 cases of encephalitis lethargica were notified in the County of London, of which 2 belonged to Stepney and 1 each to Camberwell, Hammersmith, and Poplar. The causes of 34 of the 4011 deaths in the 96 towns were uncertified, of which 6 were registered in Birmingham and 5 each in Liverpool and West Hartlepool.

Scottish Towns.—In the 16 largest Scottish towns, with an aggregate population estimated at nearly 2½ million persons, the annual rate of mortality, which had been 15·0, 14·7, and 14·3 in the three preceding weeks, further declined to 13·3 per 1000. The 286 deaths in Glasgow corresponded to an annual rate of 13·6 per 1000, and included 23 from whooping cough, 3 from infantile diarrhœa, 2 from diphtheria, and 1 each from measles and scarlet fever. The 118 deaths in Edinburgh were equal to a rate of 13·8 per 1000, and included 6 from diphtheria, 2 from scarlet fever, and 1 each from measles, whooping cough, and infantile diarrhœa.

Irish Towns.—The 97 deaths in Dublin corresponded to an annual rate of 12·0, or 4·9 per 1000 below that recorded in the previous week, and included 1 each from whooping cough and diphtheria. The 112 deaths in Belfast were equal to a rate of 13·9 per 1000, and included 3 from whooping cough and 1 each from measles, diphtheria, and infantile diarrhœa.

The Services.

ROYAL ARMY MEDICAL CORPS.

F. E. Feilden, late temp. Maj., to be temp. Maj.

Capt. P. D. Warburton retires, receiving a gratuity.

Temp. Capt. C. C. Chance relinquishes the actg. rank of Maj.

Temp. Capts. relinquishing their commns. on appt. to the Ind. Med. Serv.: F. M. Kirwan, S. R. Prall, and F. R. Thornton.

Temp. Capt. O. E. Finch, relinquishes his commn. and retains the rank of Capt.

To be temp. Lts.: W. E. Barnes and C. A. Lindup.

ARMY DENTAL CORPS.

Capt. A. R. Inglis, Dental Surg., late Spec. List, to be Capt.

F. D. Neal to be temp. Lt. whilst empld. as a Dental Surg.

DEFENCE FORCE.

To be Asst. Dirs. of Med. Servs.: Temp. Cols. G. H. Edington (D.F.), L. J. Blandford (D.F.), F. G. Proudfoot (D.F.), D. Rorie (D.F.), H. T. Samuel (D.F.), E. A. Wraith (D.F.)

To be Dep. Asst. Dirs. of Med. Servs.: Temp. Majs. F. W. Squair (D.F.), C. J. Martin (D.F.), H. A. Leebody (D.F.)

To be temp. Maj.: J. B. Batchelor.

To be temp. Capts.: W. J. M. White, D. Craig, S. S. Greaves, D. C. MacLachlan, and W. J. C. Watt.

To be temp. Lt.: G. L. Lyon-Smith.

1st (Highland) Fd. Amb. (D.F.).—To be temp. Lt.: G. M. Gray.

3rd (Northumbrian) Fd. Amb. (D.F.).—To be temp. Capt.: A. C. Barker.

44th (Home Counties) San. Sect. (D.F.).—To be temp. Capt.: S. W. Hoyland.

N. Midland Divl. San. Sect. (D.F.).—To be temp. Lt.: H. J. Morgan.

2nd (S. Midland) Fd. Amb. (D.F.).—Temp. Maj. A. E. P. McConnell to be temp. Lt.-Col.

1st (Welsh) Fd. Amb. (D.F.).—To be temp. Lt.-Col.: T. Donovan.

To be temp. Maj.: E. Bull.

ROYAL AIR FORCE.

Capt. (Bt. Maj.) F. C. Cowtan, R.A.M.C., is granted a permanent commission as Squadron Leader.

The undermentioned Flight Lts. relinquish their temporary commissions on ceasing to be employed, and are ermitted to retain the rank of Capt.: S. G. Seymour d K. F. D. Waters.

THE ÆTIOLOGY OF MITRAL STENOSIS.

To the Editor of THE LANCET.

SIR,—In his lecture on Mitral Stenosis, published in THE LANCET of May 28th, Dr. Basil Parsons-Smith states that "measles, scarlet fever, small-pox, erysipelas, pneumonia, septicæmia, &c., account for a considerable number of cases" of this form of valvular disease. Can any evidence be brought forward to support such a contention? Personally I should maintain that, from the standpoint of morbid anatomy, there is no such evidence. Murmurs may appear over the heart during a febrile attack in the young, due to almost any cause, but those murmurs are not evidence of endocarditis, and disappear, leaving the heart quite sound. I cannot but think that the text-book statement regarding the numerous causes of an endocarditis which may result in chronic deformity of the valve must be due to a misinterpretation of the nature of temporary cardiac murmurs. This applies not only to systolic murmurs, but to the dull diastolic sound variously named "mid-diastolic" sound, part of a "reduplicated first" sound, or of a "reduplicated second" sound, audible at the apex. Such a sound may appear during various conditions of ill-health and not uncommonly during normal health, but both in ill-health and normal health I have frequently known it to be considered to indicate the presence of mitral stenosis by medical men. Such a sound heard in a case of measles, or some similar disease, may lead to the belief that measles has caused mitral stenosis. If we take the evidence of the post-mortem room, rheumatism and chorea, I maintain, are the only diseases worthy of consideration in connexion with the ætiology of mitral stenosis. Yet in a sense, the word rheumatic endocarditis used as the precursor of mitral stenosis may be said to be a misnomer. Rheumatism and chorea, to a less extent, affect the whole heart, the muscular and interstitial structures, as well as the lining membranes, being affected. It is not disease of the endocardium which produces mitral stenosis, but inflammation of the fibrous structures of the cusps of the valve from the apices of the columnæ carneæ to basal ring. The presence of a small bead of vegetations along the margin of the cusps of the valve during an attack of acute rheumatism or chorea may be described almost as an accident. The inflammation affects the fibrous structures of the chordæ tendineæ, and at the spot where these fibrous structures are inserted into the valve and interlace there is some thickening. The endocardium covering this inflamed band chafes against the endocardium covering the inflamed band on the opposite side. Some vegetations are the result, but they have no bearing upon the disease. The inflamed fibrous structures gradually contract. They draw the two halves of the valve together and the chordæ tendineæ also. A slowly progressive thickening and fusion of cusps and also of the chordæ tendineæ are the result. In short, it is a disease of fibrous structures, not of the lining endocardium.

The above remarks will suggest that "long-continued strain, gout, syphilis, chronic nephritis, plumbism, arteriosclerosis" are not considered to play an important part in the causation of mitral stenosis. Personally, I hold that they play *none.* Mitral stenosis commences in childhood or early adult life. It may last many years, and in very exceptional cases until over 50 years of age, but even then it has commenced in early life. In thus sweeping aside all such diseases as gout, syphilis, &c., as causes of mitral stenosis, it should perhaps be remarked that there may be one apparent exception, that exception occurs in association with calcareous disease of the aortic valve. The nature of the disease is to me obscure. It is, however, locally infective in the sense that it may send calcareous processes into the cardiac muscle or into the large flap of the mitral valve. When it sends a well-marked process into this flap it must interfere with the action of the valve, but it cannot be said to produce a true mitral stenosis. I am, Sir, yours faithfully,

Norwich, May 27th, 1921. THEODORE FISHER.

IRRADIATION AND SAFETY.

To the Editor of THE LANCET.

SIR,—I have read with considerable interest and with no little surprise the leading article upon Irradiation and Safety published in your issue of May 28th.

You state that a committee composed of radiologists, physicists, pathologists, and others has been appointed to consider this important question, and you then mention the names of those selected to serve. I note particularly that there is no extra-metropolitan representative on this committee, no representation from Scotland, and none from Ireland. Perhaps it is not within the knowledge of the existing Committee that any X ray or radium work is done outside London, but for their information and guidance I may state that in Manchester there is at the present time the second largest supply, and in the near future there will be the largest supply of radium in the United Kingdom, and that at the Royal Infirmary there is one of the most efficient and most up-to-date X ray departments in the country. Would it not be policy on the part of this very "parochial" committee to invite a few extra-metropolitan representatives of radium and X ray workers to share their responsibility, the more especially as I feel sure that they will eventually have to apply to them for much of the information they ultimately require in reference to the protection of the worker? In Manchester, such items as the blood count of the workers, the regularisation of work, the holidays of workers are matters of ancient history.

May I suggest that the Committee would be well advised to coöpt a few workers from *outside* London if they wish to present in their report anything approaching an up-to-date epitome of actual and practical experience.—I am, Sir, yours faithfully,

W. MILLIGAN,
Hon. Secretary, Manchester and District
May 27th, 1921. Radium Institute.

THE DIAGNOSIS OF DYSENTERY BY THE SIGMOIDOSCOPE.

To the Editor of THE LANCET.

SIR,—For the last five years I have been greatly interested in the diagnosis of dysentery by the sigmoidoscope, a subject which Dr. P. Manson-Bahr and Dr. A. L. Gregg have so well discussed in their paper in THE LANCET of May 28th. In an article published in the Guy's Hospital Reports for January of this year I referred to the strikingly different appearances seen with the sigmoidoscope in amœbic and bacillary dysentery. I have had the advantage over Dr. Manson-Bahr and Dr. Gregg of being afforded the opportunity of examining cases in which actual ulceration of the bacillary type was present, both in the acute stage in Salonica and in one chronic case in England. The appearance is identical with that observed in the ulcerative colitis, which occurs sporadically in England, and which I believe to be of the same nature as the bacillary dysentery of tropical countries. The ulcers are shallow, irregular in outline, varying much in size, and are separated from each other by swollen, deeply congested and easily bleeding mucous membrane. Amœbic ulcers are generally more regular in shape and deeper, and the intervening mucous membrane is normal in appearance, offering a very striking contrast to that of bacillary dysentery. I have several times also seen a very early stage of amœbic dysentery in which small round projections from the mucous membrane are present, some—but not all—of which show a minute central area of necrosis surrounded by a red areola, corresponding exactly to the condition illustrated in the second plate in Sir Leonard Rogers's book on Dysenteries.

It is extremely interesting to watch with the sigmoidoscope from day to day the rapid healing of amœbic ulcers under treatment with emetine, and that of bacillary ulcers with antidysenteric serum. Quite apart from the question of diagnosis, the instrument is of the greatest value in determining when the condition should be regarded as cured. As I pointed out already in the first edition of my book on *Medical Diseases of the War*, in 1916, I have several times found that ulcers were still present when all symptoms had disappeared and the stools had become perfectly normal. Treatment should always be continued until the sigmoidoscope shows that all trace of active disease of the mucous membrane has disappeared.

I am, Sir, yours faithfully,

New Lodge Clinic, Windsor Forest, ARTHUR F. HURST.
Berks, May 30th, 1921.

ABDUCTION PARALYSIS IN EXOPHTHALMIC GOITRE.

To the Editor of THE LANCET.

SIR,—In the report of the proceedings of the Laryngological Section of the Royal Society of Medicine in your issue for May 21st (p. 1081), I am stated to have suggested in regard to a case of bilateral recurrent laryngeal paralysis and exophthalmos that the "symptoms" might have been due to pressure exerted by the enlarged thyroid gland on the sympathetic nerve. I intended to refer only to the exophthalmos, and to convey that the goitre which could produce paralysis of the recurrent laryngeals was unlikely to be the goitre of Graves's disease. The exophthalmos, therefore, might require a special explanation, such as irritation of the sympathetic produced by the pressure of an enlarged thyroid body.—I am, Sir, yours faithfully,

JAMES DUNDAS-GRANT.

Harley-street, W., May 24th, 1921.

TREATMENT OF ACUTE TOXÆMIA.

To the Editor of THE LANCET.

SIR,—The cells of many types of living beings, unicellular and multicellular, secrete poisons—endotoxins for defensive and exotoxins for offensive purposes. The microbes of disease, insects, snakes, and numerous plants furnish examples. All our vegetable medicines are endotoxins which, by means of poisonous action, often combined with disagreeable taste, protect the producing plants from animal enemies. In chronic diseases (e.g., tuberculosis and leprosy) the poisons are mainly endotoxins; in acute diseases (e.g., measles, pneumonia, diphtheria, septicæmia) they are exotoxins. Fever is a reaction to toxæmia. While experience of some poisons—for example, strychnine, quinine, and tuberculin—confers little or no added power of resistance, it is possible to train the individual to increased tolerance of other poisons—for example, nicotine, opium, snake and insect venom, and the toxins of the acute diseases. It is unnecessary to discuss the vexed question as to how this tolerance arises; bacteriologists have formulated many suppositions; but, presumably it is, in essence, what biologists call "a useful acquirement," a product of functional activity, an habituation. The individual becomes "used" to, accustomed to, educated to toxins, and, in recovery from acute disease, his cells, no longer poisoned to impotence, are able, as a consequence, to attack and destroy the pathogenic organisms. Hence recovery and acquired immunity, temporary or permanent.

This habituation may be achieved in three distinct ways. (1) By beginning with small, and proceeding to larger and larger doses of toxin, as in tobacco and opium smoking, and when diphtheria toxin is administered to a horse during the manufacture of antitoxin. (2) By beginning with and maintaining in action one large dose, as happens in acute disease which is followed by recovery. (3) By antitoxin and vaccine treatment, the rationale of which, as I say, need not be discussed.

The second method is exceedingly dangerous and is the cause of death in disease. The last method has been attempted in many infections, but as yet it has been conspicuously successful in only a few acute diseases—e.g., diphtheria and small-pox. Were it possible in acute illness to combine antitoxic serum with small doses of toxin, we should have an ideal method of cure. But sera for many acute diseases are lacking. Moreover, in illness the patient is already suffering from a large dose of toxin, which the introduction of small doses from outside would only make larger. Consequently, during illness, the only conceivable method of causing a sufferer to experience small doses is to reduce the amount of toxin in him. I do not know that this has ever been consciously attempted. I believe, however, it is not impracticable. In other words, I believe it is possible to abstract toxin from a sufferer.

Consider lobar pneumonia. A portion of the lung is invaded by the pathogenic organisms; blood is extravasated; and that portion of the lung becomes more or less solid. The temperature rises, rigors occur, the patient suffers from headache, sleeplessness, and a general feeling of illness. The severity of the disease is not at all strictly proportionate to the amount of lung involved, but depends rather on a toxæmia which especially affects the heart and breathing centres. In favourable cases a "crisis" occurs about the fifth to tenth day. Commonly the patient sleeps and awakes some time later feeling much improved. His temperature has fallen, his headache, rigors, and sleeplessness have gone, and he is bathed in sweat. Apparently the condition of his lung has not altered; but later gradual resolution occurs, and the extravasated and disintegrated blood is voided as "rusty" sputum.

Sweating is nature's mode of cooling the healthy body by evaporation from the surface. But if, as usually happens in pneumonia, the patient is thickly covered with bedclothes and evaporation prevented, the temperature still falls. Presumably, therefore, something more than mere exudation and evaporation of fluid occurs in the crisis—something which in itself causes the fall of the temperature and the general improvement. I can conceive no reason for such a sudden change except a quick elimination of toxins, and, in view of the lack of evidence of increased activity in other possible channels of elimination, I cannot conceive by what road the toxins can be passed out if not by the sweat. I know of no evidence that toxins have been found in the sweat; but then I do not know that they have been sought there. Since recovery from acute diseases is associated with a falling temperature, moisture of the skin, and sleep, the administration of antipyretics, sudorifics, and soporifics was formerly common. But the medicines and the dosage generally employed depressed the heart and breathing centres, and of late it has been regarded as almost axiomatic that antipyretics and sudorifics are injurious under such conditions.

But if we give a patient, suffering from pneumonia (for example) and not already poisoned past redemption, the following dose, aspyrin 10 gr., phenacetin 5 gr., and pulv. ipecac. co. 5 gr., we get (as far as my experience goes) what has all the appearance of an artificial crisis, without depression of the heart and breathing centres, or any other ill-effects. The patient soon falls asleep, and wakes some hours later feeling much better, bathed in sweat, his temperature down, his rigors and headache gone, and his pulse and breathing improved. The signs of illness will gradually return, but they can be abolished in the same way once or twice a day till permanent improvement sets in. On such occasions the patient will be relieved and rested, and unless my experience has been unusual, his illness shortened.

Lately I myself fell ill of lobar pneumonia. I began the treatment I describe about the third day, having previously received ordinary treatment; but I know no good reason why I need have waited so long. My most vivid recollection is the immense and blessed sense of relief that followed each dose. I fell asleep within half an hour. After waking, I was able for some hours to read or converse with comfort; indeed, with little feeling of illness. I suppose I took six or seven doses in all. Within a week I was writing at my desk. On the tenth day of illness I was taken for a 30 miles motor drive in the country. On the twelfth day I was walking about visiting friends at their own houses. On the thirteenth day I was back at full medical work feeling none the worse. I am not young. I voided not rusty sputum, but bright blood, showing rapid resolution. As well as I am able to judge, at each artificial crisis toxins were eliminated in large quantities, and the body was thus presented with several small doses, instead of having to make head against one continuously large dose. Certainly, while my temperature was high I felt poisoned; during the intervals I felt, or seemed to feel, relief from poisoning. Apparently my sweat centre was roused to activity, while my heart and breathing centres were relieved by the elimination of the toxin.

I have never known ill-results follow this treatment, though it has been tried lately in a fair number of cases both by myself privately and by friends in hospital practice. The following is a fair sample of cases:—

Lobar pneumonia. Advanced stage. No improvement followed treatment. Death. Apparently the patient was poisoned beyond redemption.

Lobar pneumonia. Early stage. The temperature was taken as a guide and several doses given. This case followed a course very similar to that in my own illness. Patient was up and about on the tenth day.

Broncho-pneumonia following suicidal immersion. Only one dose was given. Sleep. Sweating. Temperature fell, and never rose again. Recovery, but "vast quantities of sputum were voided for four days."

Mild rheumatic fever. Some temporary relief followed each dose, but apparently no permanent improvement, though treatment was long continued. But aspirin has been found very useful in this disease. How does it act? Hardly as an antiseptic.

Diphtheria. Twenty thousand units of antitoxin given about the same time as the dose. Sleep. Sweating. Patient awoke declaring himself recovered. Temperature never rose again. No further treatment necessary. Presumably, in this case the swift reaction to the antitoxin occurred because much of the toxin had been eliminated. That is, serum treatment was combined with a small dose of toxin.

Threatened breast abscess a week after child-birth. Temperature 101·5°F. Sleepless. Acute headache. Bad mental condition. Dose given. Slept. Sweated. Awoke feeling much better in mind and body. Temperature normal. Threat of abscess gone. No further treatment.

Diphtheria. Only one dose given, which apparently had no effect, good or bad.

Enteric fever. Only one dose given, which apparently had no effect.

Septic infection of ureter. Rigors. Temperature 105°. Effect of doses as in my own illness. Quick uncomplicated recovery in a week.

Two cases of pyrexia of uncertain origin. One dose given. Sleep. Sweating. Immediate recovery.

Measles in child of 6. Early eruptive stage. Severe. Cyanosed, so that mother remarked on "white appearance about mouth." Dose (1/6 adult) given at midday. Slept and later passed a good night. Next morning playing happily in bed. Temp., cyanosis, and photophobia gone. Little cough. Rash fading. Immediate recovery.

Measles in child of 7. Dose given, but little apparent next day. Dose repeated twice. Almost well third day.

Measles in child of 5. Much improved next day. Practically recovered third day.

These are sample cases. Up to now the suggested treatment has apparently given such good results in many cases that I have hopes that it will prove generally useful in the treatment of acute toxæmia—for example, in puerperal fever, surgical sepsis, tetanus, small-pox, and the like. But medicine is full of decaying mare's nests. It is never wise to trust to the experience furnished by a few cases to a few men. I venture, therefore, to ask if some of your readers, medical and surgical, will try this treatment, and either publish their results or inform me of them. Obviously, even if the treatment be useful in some acute diseases, it is sure not to be useful in others; the combination of drugs I suggest *may be improved on*; there may be a right and a wrong stage in each disease for the commencement of treatment; and so on. I suggest that in every instance the trial shall begin by giving a single dose in a single suitable case. If the results are not unfavourable, the treatment may be continued and the experiment extended. My own experience has been such that I feel very confident. But that, I suppose, is the way of all beginners. It should be noted that I suggest an *addition, not an alternative*, to ordinary treatment. The extreme simplicity of the suggested addition is liable to create scepticism; and though simplicity does not always imply inefficiency, unfortunately it often does. However, the test, and perhaps the improvement of this "reduction" treatment, is easy.

I am, Sir, yours faithfully,

Southsea, May 20th, 1921. G. ARCHDALL REID.

EARLY DIAGNOSIS IN DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—Dr. Frederic Thomson, in your issue of May 21st, brings before our profession a very serious matter in emphasising the importance of early diagnosis in diphtheria, and complains that many of the patients arriving at his hospital had been ill for some time, and consequently the toxins of the disease had had too much time for their deadly work. One common cause for delay in reporting these cases is the fear, on the part of the medical man in attendance, of sending a case into a diphtheria ward without being certain that his diagnosis was correct. To get over this difficulty, some years ago the Public Health Committee of the Wimbledon Corporation provided in their isolation hospital some observation wards, where doubtful cases could be sent at once. These cases were watched for a day or so, bacteriological examinations made, and antitoxin given, &c., and if the case turned out to be follicular tonsillitis no harm was done. The Public Health Committee also provided in a very central place in the town—viz., the fire-station—a supply of antitoxin and syringe available for every medical practitioner by day or night, so that time should not be lost in the administration of antitoxin. A good rule is in doubtful cases to err on the safe side, and give antitoxin at once, without waiting for the results of a bacteriological examination or for the disease to develop.

It seems to be that if the Public Health authorities throughout the country followed the example of the Wimbledon Corporation in the provision of "observation wards," and an available supply of antitoxin with syringe, &c., there might soon be an appreciable decrease in the mortality of diphtheria.

I am, Sir, yours faithfully,

Wimbledon, May 23rd, 1921. S. R. COLLIER.

DIGITALIS AND THE PERIPHERAL CIRCULATION.

To the Editor of THE LANCET.

SIR,—I would ask Dr. I. Harris, whose paper appeared in your issue of May 21st, how he thinks it possible to obtain an increased volume of flow per unit of time through the arterial system without either dilatation, at least, of the capillaries or rise of the blood pressure. For purposes of argument let us take Cases 1, 6, and 7 in his Table I., where, after the administration of digitalis, there is recorded an *increase of pulse pressure, but no rise in pulse-rate.* Let us also presume with Dr. Harris that an increase in pulse pressure connotes an increased cardiac output. Is it possible that the increased output recorded in line three, Case 1, passes through the arterial system per time unit, whilst both the systolic and diastolic pressures are markedly lowered, unless at least the capillaries are dilated? In Case 6 the second observation shows no rise in pulse, but an increased cardiac output; the diastolic pressure is negligibly lessened, and there is an appreciable rise in the systolic. Is not the explanation of this rise that capillary dilatation has either not occurred at all or at least not sufficient to allow, without increased intra-arterial pressure, the passage of a greater volume of blood in the same time unit? Finally, Case 7 shows, in the second observation, no rise in pulse-rate or systolic pressure, but an increase of cardiac output and a fall of diastolic pressure. It would again seem necessary to recognise that this combination suggests that digitalis is responsible for at least capillary dilatation to allow, at what is a slightly lowered pressure, the passage in the same time unit of an increased blood volume.

In other words, I contend that these cases bear out, inasmuch as conclusion is legitimate from them, what is a law of physics—namely, that an increased flow per unit of time through the arterial system can be obtained only either by increase of the lumina or rise of the intra-arterial pressure, and that, therefore, they render improbable the basis upon which Dr. Harris builds his conception of the pharmacology of digitalis.—I am, Sir, yours faithfully,

W. J. GRANT, M.D.

Fordoun, Kincardineshire, May 21st, 1921.

THE VALUE OF SANATORIUM TREATMENT.

To the Editor of THE LANCET.

SIR,—The review in THE LANCET of May 21st of the twenty-fourth annual report of the Loomis Sanatorium, New York, deals a much needed blow at the pessimism which has been so prevalent lately in this country with regard to the results of sanatorium treatment for pulmonary tuberculosis. I have recently read an article by a tuberculosis officer in which he arrives at the astonishing conclusion that cases do better in their own homes than in a sanatorium. This may be true in the case of some industrial sanatoriums, judging from certain letters I have received from patients who have had the misfortune to be "treated" in such institutions; but where a sanatorium is so conducted that each individual case is treated on its merits, there can be no question of the benefit of sanatorium treatment, as shown by the results at the Loomis Sanatorium. This cannot be done without sufficient staff and proper equipment, and I am very glad that you have called attention to the inadequacy of both in the public sanatoriums of this country. An X ray installation is a necessity for the proper investigation and treatment of pulmonary tuberculosis, more especially for the control of treatment by artificial pneumothorax, and no sanatorium can be said to be functioning properly if this method of treatment is not utilised in a proportion of cases. It is gratifying to find that dental treatment is considered so important at the Loomis Sanatorium; I have long held a similar opinion, but, further, I think that sufficient attention has not been paid to the hygiene of the upper air-passages. I have seen remarkably beneficial results following, for example, operation for drainage of septic nasal conditions. Another point commented upon in the review, and with which I heartily agree, is that the short length of stay which is the rule in industrial sanatoriums in this country probably accounts to a large extent for the unfavourable results published. Sanatorium treatment properly conducted still holds the premier place in the treatment of tuberculosis, and excellent results can be obtained in the majority of early cases and in a proportion of advanced cases.

I am, Sir, yours faithfully,
J. M. JOHNSTON, M.B., D.P.H.
Tor-na-Dee Sanatorium, Murtle, Aberdeenshire,
May 26th, 1921.

WARMING ETHER VAPOUR FOR INHALATION.

To the Editor of THE LANCET.

SIR,—Dr. K. B. Pinson drew attention last week to the danger of heating ether-laden air by an electric incandescent lamp, and in connexion with this has referred to an intratracheal ether apparatus described by men in your issue of April 2nd. While designing this apparatus I had in mind the accident described by Dr. W. J. McCardie, and have done everything possible to eliminate the risk of such an occurrence. The apparatus when properly connected is vapour-tight, the only place from which the vapour can escape, with the exception of the tube leading to the patient, is through the mercury safety valve, which is adjustable. A manometer is attached to the apparatus. By means of this the pressure at which the vapour is being delivered can easily be seen; the safety valve is therefore only a means of rendering it impossible to raise the pressure above the desired maximum.

In practice one finds that it is quite unnecessary to cause the safety valve to blow off. Furthermore, the length of rubber tubing that I advocate for use between the apparatus and the patient is at least six feet, therefore it is possible to have the apparatus a considerable distance from the patient. I have proved, by putting a thermometer in the current of vapour issuing from this tube, that by adjusting the heater it is possible to maintain a vapour at any desirable constant temperature. In my opinion it is practically impossible for any fire or explosion to take place even if the connexions are faulty.

Dr. Pinson's suggestion of warming the vapour by passing it through a length of rubber tubing placed on the patient's chest would, I think, greatly add to the risk of getting the tube pinched, and, in a number of cases for which intratracheal anæsthesia is used, the tube would impede the surgeon's work.

I am, Sir, yours faithfully,
A. W. MATTHEW,
Anæsthetist to St. Mary's Hospital, &c.
London, W., May 30th, 1921.

THE INTERNECINE VENEREAL CAMPAIGN.

To the Editor of THE LANCET.

SIR,—A writer in your columns (May 21st), signing himself "Morphologist," criticises a recent article of mine in the *Morning Post*, and appears to challenge my right as a layman to express any opinion on current controversies with regard to venereal disease. I have the greatest respect for the opinion of competent experts on subjects exclusively covered by expert knowledge. But the controversial issues with regard to venereal disease are not matters for expert pronouncement. They depend on ethical quite as much as on medical considerations. Indeed, the only medical issue that arises is whether treatment before connexion is more likely to prevent infection than treatment several hours after infection. On this point your correspondent, who says that his name proves that he ought to know his subject, is silent. He confines his argument to points on which his expert knowledge gives him no right to claim papal infallibility.

The issue between the two societies, the S.P.V.D. and the N.C.C.V.D., is very simple. Both accept the fairly obvious proposition that—to quote your correspondent's words—the "*fundamental* cause of venereal disease is the indulgence in promiscuous sexual intercourse"; both appeal to everybody to refrain from this indulgence; but both recognise that some people will not refrain. Up to this point the two societies have identically the same policy; the divergence then arises. To those men who will not refrain, the S.P.V.D. says: "Take certain precautions in advance"; the N.C.C.V.D. says: "Wait till you have had connexion and then report yourself as quickly as you conveniently can to some public institution where you will receive treatment at the public expense." Since your well-informed correspondent is silent on the relative medical merits of these two plans, I think I am entitled to assume that the former plan is more likely to prevent infection. That being so, I contend, as I argued in the *Morning Post*, that the Ministry of Health is not justified in spending public money in giving effect to the latter plan or in advertising the society that advocates that plan.

Ethically there is no distinction between the two courses. If it is ethically wrong to tell a man how he can help himself to sin in safety, it must also be ethically wrong to set up public institutions to give him a chance of escape after he has sinned. Possibly Dr. Addison and Sir Alfred Mond and the other theologians who direct the policy of the Ministry of Health may argue that their policy is less sinful because it provides less safety. But if they use that argument they confess themselves guilty of hypocrisy *in pretending that the purpose of the Ministry is the* promotion of the national health.

I am, Sir, yours faithfully,
Gray's Inn, May 24th, 1921. HAROLD COX.

To the Editor of THE LANCET.

SIR,—In his letter to you in THE LANCET of May 21st "Morphologist," attacking Mr. Harold Cox for his support of the movement for the medical prevention of venereal disease, betrays even more ignorance of the subject than that which he attributes to Mr. Cox. I adduce the following comments in justification of this proposition.

1. "Morphologist's" statement that the Society for the Prevention of Venereal Disease *recognises* the importance of the ethical factor is quite correct; but his further statement that Mr. Cox "fails as a critic" by not mentioning this fact is based on a misconception. The S.P.V.D., while recognising fully the obvious fact that venereal diseases would necessarily be reduced to a minimum, or nearly die out, if promiscuous sexual intercourse could be wholly *stayed* by *ethical or religious teaching, came into existence* solely because the Royal Commission on Venereal Disease, the National Council for Combating Venereal Diseases, and the Ministry of Health, which has all along supported the recommendations of these bodies, had completely ignored the element of immediate self-disinfection as an essential part of any practical measure for compassing a material reduction of venereal diseases. It is clear that Mr. Cox was aware of this fact, and was in no sense unfair to the S.P.V.D. by omitting to insist on the obvious.

2. "Morphologist" does not seem to know that venereal disease is strictly contagious, and can be directly prevented by personal disinfection; that disinfection is effectual in proportion to the quickness of its application; and that the N.C.C.V.D. advise the use of soap and water, which, being practically unportable, are therefore unavailable in the majority of cases. Neither does he seem to realise that, apart from soap and water, the N.C.C.'s recommendations are—moral injunctions, which have demonstrably failed as a means of prevention—and the treatment of those already infected, which never lessens the *incidence* of any disease. Yet surely even a "learned layman" ought to know that appropriate sanitation is the universally recognised method for diminishing the incidence of all diseases.

3. "M." seems not to know the facts (*a*) that both the Royal Commission on Venereal Disease and the N.C.C. ignored from the outset the discovery of Metchnikoff; (*b*) that by teaching the doctrine arising from this discovery the incidence of venereal disease was reduced in India and England to 1·5 from nearly 100, not by one medical officer, but by many; (*c*) that the War Office proposed to bring in this method (simply teaching) for the whole army; (*d*) that a member of the N.C.C. proposed "packets," which were provided.

But the men in our army were told that these packets were for "*early treatment*," and it is alleged that they obeyed this instruction. It is important to note here what "M." could scarcely be expected to know, that the fact of soldiers having used disinfectants as treatment for the disease was adduced before Lord Astor's Interdepartmental Committee as *evidence* that civilians who were taught to disinfect would use the disinfectants in a similarly erroneous manner. Further misrepresentations of the position and statements of the S.P.V.D. have been officially made and fully dealt with several times in many publications, including the book on "The Prevention of Venereal Disease," by Sir Archdall Reid. Lately the whole matter was investigated by the Birth-rate Commission, which made certain suggestions affording some possible ground for surcease of controversy between the two societies for antagonising venereal disease; but the N.C.C., who favoured the establishment of this inquiry, declined to proceed any further in this attempt.

Ought not your correspondent to have known something more about his subject before charging Mr. Cox with possibly "doing great damage to the nation" by his article in the *Morning Post*?

I am, Sir, yours faithfully,
H. BRYAN DONKIN.

May 26th, 1921.

A WIDER FIELD FOR CANCER RESEARCH.

To the Editor of THE LANCET.

SIR,—Do laboratory experiences and statistics derived from ready-made materials form too large a part of cancer research? If cancer comes from without, then the cause of breast cancer may be conveyed direct to the nipple by a contaminated hand. Can it be shown that in no case can this be so? If not, then what excuse is there for not finding out by asking 5000 women doctors and nurses to collaborate in a simple experiment? Would post-operative recurrence be less likely if a vegetarian diet were adopted, since vegetarian races are far less liable to cancer? An American physician, experimenting on a small scale, says "Yes." Experiments with a thousand cases with a like number of controls might settle this.

A case said to be one of Hodgkin's disease is alive after four years. He is doing the sun-cure. Would exposure to light and air influence metabolism in the direction of retarding recurrence in malignant disease? Naked or almost naked races are very little troubled with the disease. The homes of absolutely bedridden persons, and of children, who develop malignant disease, present environments which are unique. A group of expert bacteriologists, entomologists, and public health men might well be employed in examining the surroundings of all such cases. My experience is that this is not done, yet one factor might be discovered common to all. Compulsory disinfection of houses and clothes in one area, the covering and cleaning out of cisterns and covering of food in another, and perhaps an elaborate onslaught on vermin in a third, might be attempted. The Isle of Wight and Isle of Man might be used for such experiments. Is there any case at all for creating special conditions for statistical purposes—not necessarily those mentioned above? I think there is.

I am, Sir, yours faithfully,
PERCY GULLY.

Leysin, May 23rd, 1921.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, MAY 25TH.

Taxation and National Economy.

ON the motion for the Second Reading of the Finance Bill, Lord R. CECIL complained of the heavy burden of taxation imposed on income-tax and super-tax payers. Direct taxation on a small minority of the population was he said, the very worst form of indirect taxation. He was, satisfied that any system by which they tried to raise the whole of the revenue of the country from the present income-tax payers would be very disastrous. It was not in the least true that the people who were not taxed did not pay. They paid, but without in the least knowing it, and without any direct knowledge of the consequences involved in excessive taxation. All taxation was evil, and had a discouraging effect on industry. The only sound financial policy of the country at the present moment was economy. The Government apparently after prodigious efforts could succeed only in keeping taxation no higher than it was at the present time. That was a most disappointing result.

Sir R. HORNE (Chancellor of the Exchequer), replying to the debate, said he was afraid there was no opportunity for enthusiasm at the present time in matters of finance. It was a question of grinning and bearing the condition in which we were, and facing and confronting facts, rather than by lamenting and bemoaning. The present year was going to have a very testing effect upon the courage and stability and steadiness of our people. But he felt no pessimism whatever about the situation. He was sure that once we emerged from our present troubles the nation would settle down to work with a will which we had not known since the armistice, and he was equally certain that if we confronted the situation with courage we should conquer it by our perseverance and our industry.

The Second Reading of the Bill was carried by 213 votes to 16.

Round-table Liquor Conference.

Major KELLEY asked the Prime Minister the terms and personnel of the round-table conference on liquor restrictions and licensing reform.—Mr. CHAMBERLAIN replied: I hope to make a statement upon this matter in the course of next week.

THURSDAY, MAY 26TH.

A Case of Trench Feet.

Mr. GLANVILLE asked the Minister of Pensions whether he was aware that Frederick Dimmock, No. G. 531161, of the Royal Fusiliers, who is a miner and joined up in 1916, when he was passed A1, served in France till May, 1917, when he was sent home with trench feet to the hospital; that his toes were amputated on August 15th, 1919, and he had to return to hospital for an operation; that he was unable to walk owing to intense pain; that he has a wife and child and had no other means beyond his pension and the unemployment benefit which would shortly end; that the medical reference recommended 80 per cent. pension; and that this had since been reduced to 8*s.* 3*d.* per week, though he was quite unable to work for a living; what action he proposed to take in this case, and whether the man in question could come before a medical appeal board.—Mr. MACPHERSON replied: The disabilities in this case are disorderly action of the heart (attributable to service); hammer toes—not trench feet—and varicose veins (both aggravated by service). The little toe of one foot has been amputated. Aggravation of the hammer toes having passed away no pension for that disability can be awarded therefor. Disablement from the other disabilities was assessed at 30 per cent. by a Medical Appeal Board in July, 1920, and a pension of 12*s.* a week will be in payment until July 19th, 1921. Following that day the rate will be reduced to 8*s.* per week, a recent Survey Board, held with a view to renewal of the award, having assessed disablement at 20 per cent. There is a right of appeal through the Local War Pensions Committee to a Medical Appeal Board against the assessment of 20 per cent. and to the Pensions Appeal Tribunal against the decision that aggravation in the case of the hammer toes has passed away.

Grants for School Camps.

Mr. TREVELYAN THOMSON asked the President of the Board of Education whether he was aware that, notwithstanding the recommendation of the chief medical officer to the Board that school camps should be encouraged, local education authorities were seriously handicapped in making these arrangements by the rulings of the Board that attendance at lessons given at such camps cannot be reckoned on the school register of attendances if any charge was made to cover the cost of food or any other item of expenditure in connexion with these camps; and, if the Act of 1918 prohibited such charges, could he see his way to bring in an amending Bill to enable local authorities to organise school camps and make a charge to cover the cost of food, which would otherwise be provided by parents, and at the same time count the attendance at lessons given in these camps in the school register so as to qualify for grants.—Mr. Herbert Lewis (Parliamentary Secretary to the Board of Education) replied: My right honourable friend understands that the honourable Member is concerned with children who receive instruction elsewhere than at the school in accordance with arrangements approved under Article 44 of the Code, and not under Section 17 of the Education Act of 1918, though the conditions under which they receive such instruction are those of a camp. It appears to him that in such a case the local education authority are competent to exercise their powers under the provision of Meals Acts, 1906 and 1914. The power to make a charge under those Acts is expressly excepted by Section 26 of the Act of 1918 from the general prohibition of charges contained in that section.

Physical Education of Boys.

Colonel Sir Charles Yate asked the President of the Board of Education whether out of the 11 inspectors of physical education appointed by the Board of Education 8 were women; and, if so, what steps he proposed to take to place men in charge of the physical education of boys.—Mr. Herbert Lewis replied: Seven of the 11 inspectors of physical training are women. My right honourable friend does not see his way to increase the establishment by the appointment of additional men inspectors.

Grants for Clinical Units in Hospitals.

Mr. Hopkins asked the President of the Board of Education whether he would supply a return setting forth the allocation of the Exchequer grants for university colleges, recurrent and non-recurrent, for the last financial year; and how much of this grant was expended in financing new departures, such as the financing of the University of Cambridge and grants towards the salaries of heads of clinical units in hospitals.—Commander Hilton Young (Financial Secretary to the Treasury) replied: Returns from universities and colleges in receipt of Treasury grants for the academic year 1919–20 have already been presented to Parliament (Cmd. 1263), and they give the information referred to by the honourable Member so far as it is yet available. Similar returns will be presented annually.

Mr. Hopkins asked the President of the Board of Education what were the principles and regulations under which the University Grants Committee was to recommend the distribution of the Parliamentary grants recently approved by Parliament for the coming quinquennium; was it an implied condition in the allocation of financial aid to university colleges from the extra grant voted by Parliament that they should obtain equal financial assistance from local authorities, and was this principle also to be applied to grants made for the formation of clinical units in hospitals; had the principle of giving building grants to university colleges been authorised, and, if so, the principles on which such grants were to be made; and was it intended to supply Government funds to raise the salaries of the more important professors in university colleges to the same figure—namely, £2000 per annum, as had been fixed for the salaries of the professors who acted as the heads of the newly instituted clinical units in hospitals.—Commander Hilton Young replied: The general principles on which the University Grants Committee base their recommendations for the allocation of grants are set out in the Report of the Committee dated Feb. 3rd, 1921, and in the letter addressed by my right honourable friend to Sir William McCormick printed as an Appendix to the Report, which has already been presented to Parliament. As there stated, great importance is attached to the amount of support provided from local sources in calculating the grants payable to the different institutions, but except in the case of the University of Wales there is no undertaking by the Government to make grants on the basis of pound for pound in respect of rate aid. The Committee are authorised to recommend capital grants for sites, buildings and permanent equipment if the funds at their disposal allow, but no such recommendations have yet been made. The responsibility for fixing the salaries of the teaching staffs rests with the authorities of each institution.

Institutional Treatment of Tuberculosis.

Mr. Ronald M'Neill asked the Minister of Health whether regulations had recently been made with respect to the institutional and other treatment of tuberculosis by councils of counties and county boroughs; whether such regulations had to be laid before Parliament for confirmation, and, if so, when they would be laid; and whether, before they took effect, an opportunity would be afforded of discussing any regulation the effect of which would be to impose an additional charge on the ratepayers.—Sir A. Mond replied: The answer to the first part of the question is in the negative, and the second part does not therefore arise. The arrangements to be made by the councils of counties and county boroughs for the treatment of tuberculosis upon the termination of sanatorium benefit and the financial proposals in connexion therewith were fully explained in the course of the debates upon the Public Health (Tuberculosis) Act, 1921, and in the White Paper which was circulated explaining the provisions of the Act and the necessary Financial Resolution.

New Liquor Regulations.

Sir John Butcher asked the Under-Secretary of State for the Home Department, as representing the Central Liquor Control Board, whether he was now in a position to publish, in the form of a White Paper or otherwise, the modifications which had been recently made in the regulations of the Central Liquor Control Board.—Sir John Baird replied: Copies of the recent Orders issued by the Central Control Board (Liquor Traffic) which have been distributed throughout the country are now available for Members. I am circulating a printed copy of the statement published by the Board in explanation of these Orders.

The following is the statement:—

"The Central Control Board (Liquor Traffic) have made Orders dated April 25th and operating on Monday, 2nd May, applicable to all Scheduled Areas in England and Wales consolidating the existing Orders and amending them in the following particulars:—

1. The prohibition of the sale and supply of spirits for consumption off the premises on Saturday is removed, and such sale and supply during the midday period (12 to 2.30 P.M.) on that day is allowed.
2. The provision which fixes a reputed quart as the minimum quantity of spirits which may be sold for off consumption together with the requirement as to the labelling of bottles, is revoked.
3. The hours after 10 P.M. for which magistrates (or, in London, the Commissioner of Police) may grant an Order or licence in pursuance of Section 57 or Section 64 of the Licensing *(Consolidation)* Act, *1910*, are extended beyond the present limit of 11 P.M.
4. The extent to which spirits may be diluted without notice to the purchaser is limited to a strength falling between 30 degrees and 35 degrees under proof.
5. The sale of intoxicating liquor to authorised messes of officers or non-commissioned officers is exempted from the operation of the Order.
6. The requirement that copies of the Board's Orders must be exhibited in every club and in every public room in licensed premises is revoked, and a requirement that copies must be kept on the premises and produced on demand is substituted therefor.

These Orders were published in the *London Gazette* of April 26th, and corresponding Orders have been made for Scheduled Areas in Scotland.

The Government have now announced that no legislation of any kind upon the subject will be possible during the present session, and they have agreed that the relaxations contained in the Orders now published, which have been held over in the expectation that the whole matter was about to be dealt with by Parliament more comprehensively and authoritatively than could be done by the Board, should be made without further delay.

The Board will now proceed to consider what further modifications can properly be made in view of the Government's announcement."

Friday, May 27th.

The Washington Conventions.

Mr. G. Barnes called attention to the fact that the Government had not yet submitted to Parliament certain conventions adopted by the International Labour Conference at Washington, and moved: "That in the opinion of this House the conventions adopted at the International Labour Conference under the League of Nations should be submitted to Parliament as the competent authority." He said that of the three Government Departments concerned the Home Office had given effect to certain of the Washington Conventions by the Act relating to the employment of women and children, and by Departmental Orders; but neither the Ministry of Labour nor the Ministry of Health had given effect to the Labour Chapter. They had failed to deal with the Eight Hours' Convention and the ex-Minister of Health had stated in that House that the Government had decided not to ratify the maternity convention, thereby indicating that the Government assumed to be a law unto themselves. Though the Government were not under an obligation to ratify the maternity convention, they were under an obligation to allow Parliament to have a look at it. If the attitude of the Government was correctly voiced by the ex-Minister of Health it meant knocking the bottom out of the Labour organisation, which would become a mere cipher in the hands of Governments. The success of the International Labour Organisation depended on results, and if there were no results the failure would delight the hearts of the Bolshevists in this country and elsewhere. It was not only unwise, but it was unfair to those who had helped to build up this labour organisation in the hope of contributing to goodwill, lessening waste from stoppages of work, and improving conditions in the poorer countries.

Dr. MACNAMARA (Minister of Labour) moved to leave out *all the words after "That," and add "in the opinion of* this House it is not expedient in existing circumstances to proceed with legislation to give effect to the Washington Convention on Hours of Labour." He said that the Government had no desire to evade their pledges in relation to the conventions. *To do so would be to fall below the* reputation of this country in such matters. The real fact was that as regards most of the conventions we had already a first-class record, and one far in advance of that of any other country. The position of the Government in proposing the amendment was that the great bulk of the proposals had already been translated into definite action and were in effective operation throughout the country.

Viscountess ASTOR said that she thought that the conscience of the country was more awake than that of the Government on the subject of maternity benefit. Before the maternity convention was turned down entirely she suggested that a committee representing women's societies should be called together in order to see what they could get out of the Washington Convention. so that it might be attached to the existing insurance scheme.

Sir M. BARLOW (Parliamentary Secretary to the Ministry of Labour) said it was not the intention of the Government to drop the Hours Bill altogether. Had the Washington Convention been drawn with a little more latitude and elasticity it would have been more easy to apply its provisions. The Cabinet had recently set up a strong Departmental Committee presided over by himself with the desire of getting all international labour matters dealt with expeditiously, and with a view of coördinating the work. With regard to the maternity convention the last word had not yet been said as to the need for further provisions for dealing with the burden of women in industry, and the appeal of Lady Astor would certainly be considered. The *Government and the* Ministry of Labour desired to work in the most cordial and close coöperation with the International Labour Office of the League of Nations.

On a division the Government amendment was carried by 100 votes to 69.

MONDAY, MAY 30TH.

Medical Officers at Pensions Ministry.

Lieutenant-Colonel CROFT asked the Minister of Pensions whether certain doctors employed by the Ministry of Pensions had had a four years' service contract given to them.—Mr. MACPHERSON replied: The answer is *in* the affirmative. With the approval of the Treasury and after consultation with my right honourable friend, the Minister of Health, a number of full-time salaried medical officers, whose employment had previously been subject to one month's notice, have been given a four years' *contract*, terminating on March 31st, 1925.

Lieutenant-Colonel CROFT asked the Minister of Pensions whether he would give an undertaking that the services of those doctors at present employed under the Ministry of Pensions who sacrificed their practices to *join the Army* and Navy at the outbreak of war and were on active service and were now dependent solely on their salaries would be retained at the Pensions Ministry in preference to those who were already drawing big pensions in addition to their salaries and those who were being kept *on* who had never served abroad.—Mr. MACPHERSON replied: Practically the whole of the full-time medical officers of the Ministry served during the late war and, other things being equal, preference for retention will continue to be given to medical officers who saw active service over medical officers in the same class who did not so serve.

TUESDAY, MAY 31ST.

Bonus to Tuberculous Trainees.

Mr. ALFRED DAVIES asked the Minister of Pensions whether any definite decision or ruling had yet been given to war pensions committees with regard to the payment of bonus to trainees who had undergone a course of training on the termination of sanatorium treatment for tuberculosis. Mr. MACPHERSON *replied: Instructions* will be given to the regional offices as soon as the necessary arrangements have been made with the Ministries of Health and Labour.

NEXT Wednesday, June 8th, the Prince of Wales will lay the foundation-stone of the new Institute of Preventive Medicine at Cardiff.

Medical News.

UNIVERSITY OF LONDON.—Dr. R. R. Gates, Ph.D. (Chicago), has been appointed to the University Chair of Botany tenable at King's College, and Mr. D. M. S. Watson, M.Sc. (Manchester), to the Jodrell Chair of Zoology and Comparative Anatomy tenable at University College. Mr. H. G. Jackson, M.Sc. (Liverpool), has been appointed to the University Readership in Zoology tenable at Birkbeck College, and Dr. William Wilson, Ph.D. (Leipzig), D.Sc. (London), to the University Chair of Physics tenable at Bedford College.

At examinations held recently the following candidates were successful:—

THIRD (M.B., B.S.) EXAMINATION FOR MEDICAL DEGREES.

Girdhar C. Agarwala, London Hosp.; Doris Elizabeth Alcock, London Sch. of Med. for Women; Christopher H. Andrewes (honours, distinguished in medicine, forensic medicine, and surgery, University medal), St. Bart.'s Hosp.; Wilfred M. Anthony, St. Thomas's Hosp.; James R. Banks, Univ. Coll. Hosp.; Mary Rushton Barkas, St. Mary's Hosp.; Frank M. Barnes, St. Thomas's Hosp.; Henry E. Beasley, Univ. Coll. Hosp.; Ursula Pousett Blackwell, London Sch. of Med. for Women; Harold J. Blampied, St. Thomas's Hosp.; John Brodie and Philip C. P. Cloake, London Hosp.; Florence R. Clulow (honours, distinguished in pathology) and Eric V. Corry, Univ. Coll. Hosp.; Elsie E. Cowperthwaite, St. Mary's Hosp. and London Sch. of Med. for Women; Llywelyn ap Ivan *Davies, Univ. Coll. Hosp.*; Archibald G. Duncan, London Hosp.; Edith M. Evans, St. Mary's Hosp. and London Sch. of Med. for Women; Ada M. Freeman, King's Coll. Hosp.; Isaac Frost, St. Bart.'s Hosp.; Madeline Giles, St. Mary's Hosp.; Henry A. Harris (honours, distinguished in forensic medicine), Univ. Coll. Hosp.; Frank Heber, London Hosp.; James G. Jones, *Guy's Hosp.*; *Dorothy* M. Kemp, London Sch. of Med. for Women; M. Kathleen Forsaith Lander, St. Mary's Hosp.; Eugene H. L. Leclezio, Guy's Hosp.; Reginald C. B. Ledlie (honours, distinguished in surgery), Guy's Hosp.; Harold W. Lewis, Middlesex Hosp.; Rhys T. Lewis, Univ. Coll. Hosp.; Margaret Longbottom, London Sch. of Med. for Women; Edward R. Lovell, Middlesex Hosp.; Gerald J. W. McMichael, Univ. Coll. Hosp.; Henrietta A. C. Main, St. Mary's Hosp.; Arthur G. Maitland-Jones (honours, distinguished in medicine), London Hosp.; Claude H. Marshall, Guy's Hosp.; Adeline M. Matland, London Sch. of Med. for Women; Kathleen H. Matthews, St. Mary's Hosp. and London Sch. of Med. for Women; Victor E. Negus, (honours, distinguished in forensic medicine), King's Coll. Hosp.; Sybil M. Nuttall, St. Mary's Hosp.; Sybil G. Overton, St. Mary's Hosp. and *London* Sch. of Med. for Women; Robert H. Parry, Middlesex Hosp.; Phœbe M. Phillips and Alice D. Pocock, London Sch. of Med. for Women; William R. Rowlands, Liverpool Univ.; Gordon W. R. Rudkin, Univ. Coll. Hosp.; Herbert L. Sackett, St. Bart.'s Hosp.; Ahmad; Shafeek, St. Thomas's Hosp. and Kasr El-Ainy Hosp.; *Bryan B. Sharp*, St. Bart.'s Hosp.; Katherine J. Shaw, London Sch. of Med. for Women; Philip Steinberg, (honours, distinction in medicine), London Hosp.; Lionel F. Strugnell, St. Bart.'s Hosp.; Richard N. L. Symes, St. Thomas's Hosp.; Raghunath Sabaji Tirodkar, Univ. Coll. Hosp. and Grant Med. Coll., Bombay; Norah E. Trouton, St. Mary's Hosp.; Arthur E. Ward and Sydney A. T. Ware, St. Thomas's Hosp.; Robert W. Warrick, Guy's Hosp.; Frederick W. A. Watt, London Hosp.; Agnes E. Westwood, St. Mary's Hospital; Idwal Glynne Williams and William P. Wippell, St. Bart.'s Hosp.; and Wilfrid C. S. Wood, King's Coll. Hosp.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—E. D. Fenwick (Sects. I. and II.), St. Mary's Hosp.; H. L. Sheehan (Sect. I.), Manchester; and J. Solomonoff (Sects. I. and II.), London Hosp.

Medicine.—F. E. Edwards (Sect. II.), Manchester; M. A. K. El Hennawy (Sects. I. and II.), and E. D. Fenwick (Sects. I. and II.) St. Mary's Hosp.; O. E. Finch (Sects. I. and II.), Toronto; A. Mishriky (Sect. I.), St. Mary's Hosp.; and H. L. Sheehan (Sect. I.), Manchester.

Forensic Medicine.—F. E. Edwards, Manchester; M. A. K. El Hennawy and E. D. Fenwick, St. Mary's Hosp.; O. E. Finch, Toronto; H. L. Sheehan, Manchester; M. Tcherny, Zurich; and R. E. Williams, Guy's Hosp.

Midwifery.—M. A. K. El Hennawy and E. D. Fenwick, *St. Mary's Hosp.*; M. Fox, Charing Cross Hosp.; A. Senn, London Hosp.; and H. L. Sheehan, Manchester.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: E. D. Fenwick and J. Solomonoff.

VISIT OF MEDICAL MEN TO AIX-LES-BAINS AND THE SWISS SPAS.—At the invitation of the managers and with the coöperation of the French and Swiss railways, two parties of medical men from this country are visiting Aix-les-Bains and a number of Swiss spas. The itinerary includes *Chamonix*, Montana, Leuk, Ragaz and Tarasp. The first party of 20 leaves on June 25th under the personal guidance of Sir Henry Lunn.

Royal College of Surgeons of England.—An ordinary meeting of the Council was held on May 12th, Sir Anthony Bowlby, the President, in the chair.—The President presented Mr. Harold Burrows, C.B.E., with the Jacksonian prize, Dr. James Sim Wallace with the John Tomes prize, Mr. W. Kelsey Fry with the Cartwright medal and prize, and Mr. Kenneth Parsons with the certificate of his appointment as Begley student.—A report was read from the Court of Examiners respecting candidates found qualified for the Diploma of Member of the College, and diplomas were awarded to 103 candidates mentioned in the report.—A report was read from the Secretary to the Conjoint Examining Board respecting candidates found qualified for the Diploma in Public Health of the Royal College of Physicians of London and the Royal College of Surgeons of England, and diplomas were granted jointly with the Royal College of Physicians to 23 candidates mentioned in the report.—A report was read from the Secretary to the Conjoint Board respecting candidates found qualified for the Diploma in Tropical Medicine and Hygiene of the two Colleges, and diplomas were granted to 21 candidates mentioned in the report.—It was resolved to inform the British Dental Association that the Council were not prepared to institute a Diploma in Public Dentistry at the present time.—A report from the Committee of Management was read announcing that Sir Charles Ballance, the visitor appointed by the Royal Colleges to inspect the examinations of the Egyptian Medical School and Hospital, Cairo, had sent a full and interesting report on the examinations and teaching of the Medical School and Hospital, and that they (the Committee) were of the opinion that the examinations and course of education justified the Royal Colleges in continuing their recognition of the School. It was resolved that the best thanks of the Council be given to Sir Charles Ballance for his services. —The President reported that he had placed the lecture theatre of the College at the disposal of the University of London for a course of four lectures by Prof. Edward Mellanby, of the University of Sheffield, on "Some Actions of Foodstuffs in the Production and Treatment of Disease," to be delivered on June 6th, 7th, 13th, and 14th.—The President reported that the *terms of office* of Mr. R. Lawford Knaggs and Mr. J. Hutchinson as members of the Court of Examiners would expire on June 8th next, and that the vacancies thus occasioned would be filled up at the ordinary Council on June 8th.—Sir Squire Sprigge was introduced, and admitted a Fellow of the College.

Epsom College.—The annual general meeting of the governors of this medical foundation will be held at 49, Bedford-square, London, W.C., on Friday, June 24th, at 1 P.M., when the result of the voting for pensioners and foundation scholars will be announced.

Society for the Prevention of Venereal Disease.—The second annual *general meeting* of this society will be held at 5.30 P.M. on Monday, June 6th, at the Barnes Hall, 1, Wimpole-street, London, W., kindly lent by the Royal Society of Medicine.

Tuberculosis Society.—A general meeting of this Society will be held at the Margaret-street Hospital, Margaret-street, Oxford-street, London, W.1, on June 6th, at 7.30 P.M., when the President, Dr. Nathan Raw, will read a paper.

University College Hospital.—The Ladies' Association will hold a sale on Wednesday, June 8th, from 11.30 A.M. to 7 P.M., at Someries House, Regent's Park, London, N.W.1. Princess Helena Victoria will open the sale, at which special features will be an antique stall and a second-hand book-stall.

Exhibition of X Ray Photographs.—At the Royal Photographic Society's exhibition, opened this week at 35, Russell-square, London, W.C., there is an important section of X ray photographs under the auspices of the Rontgen Society. Comprising upwards of 250 prints, it includes a number of examples from French workers, sent over by special æroplane. In the competition for prizes offered by Dr. R. Knox, president of the Rontgen Society, first prize was awarded to Mr. Suggars, of the London Hospital, and the second to Mr. A. O. Forder, of King's College Hospital. The exhibition *remains* open during June, from 11 A.M. to 5 P.M.

Donations and Bequests.—The Trustees of Smith's Charity have contributed £500 to the Royal Waterloo Hospital.—The residue of the estate of the late Mrs. Sarah J. Fellowes, amounting to some £5000, will be divided equally between St. Dunstan's Hostel for *Blinded* Soldiers and the Church Army.—The executors of the late Frank Rigby, of Abbots Heyes, Chester, have allocated to the Chester Royal Infirmary £10,000. This gift will be used for the endowment of a ward in memory of Mr. Rigby's nephew, who was killed in Palestine.

The National Medical Union.—During the afternoon of Saturday, May 28th, the eighth annual general meeting of the National Medical Union was held at 11, Chandos-street, Cavendish-square. The main subject for discussion was the creation of a body really representative of the medical profession, and having an influence on its destinies commensurate with that representation. The object of their meeting, as stated by Dr. Blackhall-Morison in an introductory address, was to devise means whereby medicine might regain control of its own development and activities. He pointed out that the preservation of the traditional esprit de corps of the profession was greatly to the benefit of the public; its ethic should be consistently taught together with the theory and practice of medicine. The physician is neither judge nor policeman, and should never be used as such by the *administrators* of justice in the case of those whom he has attended professionally. The sanctity of the Hippocratic oath should know no exception; it would not hinder the assistance which the medical man can give in the detection and punishment of crime in which his technical knowledge is of service. The growth of knowledge of prevention and of epidemiology had resulted, he said, in the rise of a medical civil service dealing with public medicine. In certain conditions medical men had to be regarded in the aggregate, as in the naval, military, and Poor-law services: members of these services, together with public health officers, would wisely be represented in a central body representative of the entire profession. In such a body the Colonial profession should be represented; the whole would constitute an Imperial Medical Council, a term implying local councils, coördinated with an Imperial centre but absolute in their own spheres. In such an arrangement would lie the germ of an international medical power beneficial to the whole of mankind. The General Medical Council, as at present constituted, could in no sense be regarded as representative of the entire profession; each directly represented member represents between seven and eight thousand members of that profession. The bodies chiefly constituting the Council had maintained an absolute passivity in recent important legislation affecting the profession. *To this anomalous situation* the National Medical Union must now address itself, in order to establish such a body as the Government, speaking through the Minister of Health, has stated its desire to negotiate with matters of professional interest. Outside the General Medical Council several other bodies regard themselves as generally representative of the profession, but their claims are not admissible; in the General Medical Council itself, the Medical Union contends, there lies the germ of an adequate professional organisation. With the nominated element as it now exists no fault can be found; but for adequate representation 500 members of the profession should be regarded as a unit, resulting in a Government *or Parliament of medicine containing 100 members*—31 nominated as at present, and the remainder representative; direct representation would then give London 14 members, Provincial England 33, Wales 2, Scotland 8, Ireland 6; the Services might be represented by 3 members, and the Colonies by 6. There would be no great difficulty in the financing of such a body or in establishing its relationship to the Government.

In the evening the Annual Dinner of the General Medical Union was held at the Café Monico, Piccadilly Circus; the chair was occupied by Dr. Blackhall-Morison. After the loyal toast had been drunk the toast of the National Medical Union was proposed by Professor William Russell, *President of the Union*, who *defined the causes for which* the Union stood as those of freedom of the medical profession from State interference in its affairs, and freedom of the public in their relations with medical men. No doubt, he said, the State had certain medical duties to perform, but the Medical Union held that it exceeded those duties when the National Insurance Act was introduced. State interference had had a disastrous effect on the profession and on its high ideals; the sense of individual responsibility for individual patients was being destroyed in the medical man, and with it the self-help and independence which had been the glory of the working class of this country. Dr. Blackhall-Morison, responding, described the medical profession as the least organised *portion of mankind*; he regretted its apathy in the matter of professional interests and also the ingorance which held many medical men back from what they considered to be political matters. Dr. V. T. Greenyer, who proposed the health of the Scottish Medical Guild, briefly described the origins of the Guild, of the London Medical Committee, and of the National *Medical Union*, which bodies had come into being to combat the State socialism rampart during the war and afterwards. He referred to the recent circularisation of the medical profession in Scotland by the Medical Guild on the subject of the Interim Report of the Consultative Council to the Ministry of Health, which had shown the majority of that portion of the profession to disapprove both of the extension of national insurance and of the terms of the Interim Report.

NORTH OF ENGLAND TUBERCULOSIS SOCIETY: POST-GRADUATE COURSE.—A small party attended the course recently held in Paris under the auspices of the Society. The visitors were impressed with the work being done at Berck-Plage for crippled children and the arrangements for treatment of pulmonary cases at Bligny sanatorium, and especially with the thoroughness in diagnostic methods and treatment of Dr. E. Rist at the Laennec Hospital, where artificial pneumothorax is practised. The members were *hospitably welcomed at the various institutions* visited, and appreciated the courtesy and helpfulness of Dr. Rist and his colleagues Dr. E. Sorrel, of Berck-Plage, Dr. Guinard, of Bligny, Dr. Besredka, of the Pasteur Institute, and Dr. Williams and Dr. Soper, of the Rockefeller Commission in France.

PAYING PATIENTS IN THE BRISTOL VOLUNTARY HOSPITALS.—The two principal voluntary hospitals of Bristol, the Royal Infirmary and the General Hospital, have simultaneously decided upon the collection of payments from patients; a guinea per week from in-patients, and a small fee at registration and on subsequent visits from out-patients. Each institution will appoint an almoner, and it is to be clearly explained to all patients that their contributions are towards the cost of maintenance and in no sense *payment for the services of* the honorary staff. The proposals are frankly experimental, and designed to meet the present financial emergency. The Royal Infirmary, it may be added, has recently received from its President, Mr. H. H. Wills, a present of securities sufficient to bring in about £5000 per annum.

ANTI-VIVISECTION HOSPITAL (BATTERSEA GENERAL HOSPITAL, INC.).—Lord Tenterden, who presided at the annual court of governors of the hospital on May 26th, said that it was highly satisfactory that during the past 11 years this hospital—so far as he knew, the only hospital of its kind in the world—could show an excess of income over expenditure. Nevertheless, the board would have to consider the *necessity of closing* down some of the wards unless a more assured annual income was forthcoming. The number of out-patient attendances in 1920 was 11,557, 6000 more than the year before. Mr. Steward, representing the Hospital Saturday Fund, said that when he visited that beautiful hospital the patients told him they could not be more kindly or efficiently treated, and he could only say that *it was worthy of* whole-hearted support. The retiring members of the board were *re-elected.*

NEW ASSOCIATION OF SCOTTISH WOMEN'S HOSPITAL UNITS.—A meeting was held on May 30th *in the building* of the Gynæcological and Obstetric Unit of the Royal Free Hospital of past *members and* friends of this unit, to discuss the formation of an association to endow or maintain beds in the unit, of which Professor Louisa McIlroy is the director. A resolution in favour of such an association was passed unanimously, and a committee was formed. Lady Selborne presided, and among the speakers were Mrs. Russell, M.D., Miss F. Ivens, M.S., and Sir Courtauld Thomson, who paid a *tribute to the excellent* work done by the hospital units under Professor McIlroy in Salonica and in *Constantinople*, and congratulated the Royal Free Hospital on having secured her services. The cost of maintenance of each bed is £200 a year. Donations and subscriptions should be sent to Miss Dorothy Willis at *the* Royal Free Hospital, Gray's Inn-road, W.C.1.

LONDON SCHOOL OF TROPICAL MEDICINE.—A prize has just been instituted at this school in memory of the late Dr. W. H. Langley, C.M.G., Principal Medical *Officer* of Southern Nigeria. Dr. Langley died in the year 1912, and the fund was raised principally *on the coast.* The war intervened and all the papers, subscription lists, &c., *went down in the s.s. Umgeni*, when Dr. Lynch Burgess, of the West African Medical Service, who was treasurer, lost his life. Dr. Thomas Hood, C.M.G., and Major Gerald Bell, two of those originally connected with *the movement*, have made arrangements for setting up the memorial in connexion with the school. *The prize (about* £30) is to be awarded triennially and is open to competition among *officers of the West African* Medical Staff, whether on the active or retired list. The award will be made in respect of the best paper written on one of the following subjects: (*a*) Tropical Medicine or Surgery; (*b*) Tropical Hygiene and Sanitation; (c) Tropical Entomology and Parasitology. The first award will be made *in the* year 1921. Papers should be delivered to the Secretary, Seamen's Hospital *Society, Greenwich, London*, S.E., on or before Oct. 1st, 1921.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.
THURSDAY, June 9th.—*Papers:—Prof. C. S. Sherrington*: Break-shock Reflexes and "Supramaximal" Contraction-response of Mammalian Nerve-muscle to Single-shock Stimuli. Mr. R. J. Ludford and Mr. J. B. Gatenby: Dicytokinesis in Germ Cells, or the Distribution of the Golgi Apparatus during Cell Division (communicated by Prof. J. P. Hill). Dr. F. W. Edridge-Green: The Effect of Red Fatigue on the White Equation (*communicated by Prof.* W. M. Bayliss). Mr. E. Ponder: A Method for investigating the Hæmolytic Activity of Chemical Substances (communicated by Sir E. Sharpey Schafer). Mr. W. H. Pearsall: The Development of Vegetation in the English Lakes, considered in Relation to the General Evolution of Glacial Lakes and Rock Basins (communicated by Mr. A. G. Tansley).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.
THURSDAY, June 9th.—5 P.M., Croonian Lecture:—Dr. F. L. Golla: The Objective Study of Neurosis.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
MONDAY, June 6th.—12.15 P.M., Dr. Burnford: Pathological Demonstration. 2 P.M., Dr. S. Pinchin: Medical Out-patients. Dr. Morton: X Ray Department. 2.30 P.M., Mr. Baldwin: Demonstration of Cases, Surgical Wards. 5 P.M., Lecture:—Dr. A. Saunders: Gastric Disorders in Adults.
TUESDAY.—10 A.M., Mr. *Steadman*: Dental Department. 11 A.M., Dr. McDougal: Electrical Department. 12 noon, Mr. T. Gray: Demonstration of Fractures. 2.30 P.M., Dr. Pritchard: Demonstration of Cases, Medical Wards. 5 P.M., Clinical Lecture:—Mr. Banks Davis: Throat, Nose, and Ear.
WEDNESDAY.—11 A.M., Mr. MacDonald: Demonstration of Cystoscopy. 12 noon, Mr. Sinclair: Surgical Diseases *of the Abdomen.* 2 P.M., Mr. D. Armour: Visit to Surgical Wards. Mr. Gibb: Eye Department. Dr. Owen: Medical Out-patients. 5 P.M., Lecture:—Dr. Morton: Carbon *Dioxide Snow.*
THURSDAY.—10.30 A.M., Dr. Simson: Gynæcological Demonstration. 12 noon, Dr. S. Pinchin: Diseases of the Heart. 2 P.M., Mr. Bishop Harman: Eye Department. Mr. Baldwin: Orthopædic Department. 5 P.M., *Special Lecture*:—Dr. A. Eichholz: Extraordinary Children—their Treatment and Management (open to all Medical Practitioners).
FRIDAY.—10 A.M., Dr. *G. Stewart*: Neurological Demonstration. Mr. D. Buxton: Dental Department. 2 P.M., Dr. Burnford: Medical Out-patients. Mr. T. Gray: Surgical Out-patients. *Dr. Pernet*: Skin Department. 5 P.M., Lecture:—Mr. MacDonald: *Retention of* Urine.
SATURDAY.—10 A.M., Dr. A. Saunders: Medical Diseases of Children. 2 P.M., Mr. Sinclair: Surgical Out-patients.
Daily:—10 A.M., *Visit of* Post-graduates to Wards. 2 P.M., In-patient, Out-patient Clinics and Operations.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, W.C. 1.
MEDICAL SCHOOL.
MONDAY, June 6th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Lecture:—Dr. *Russell* Reynolds: X Ray Demonstration of Spinal Cases.
TUESDAY, June *7th*.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Lecture:—Mr. Armour: Surgical Treatment of Spinal Cord Tumours (I.).
THURSDAY, June 9th.—2 P.M., *Out-patient* Clinic: Dr. Farquhar Buzzard. 3.30 P.M., Lecture:—Dr. Kinnier Wilson: Tumours of Spinal Cord (II.).
FRIDAY, June 10th.—2 P.M., Out-patient *Clinic*: Dr. Gordon Holmes. 3.30 P.M., Lecture:—Mr. Sargent: Surgical Treatment of Exophthalmic Goitre.
NEUROLOGICAL OPHTHALMOLOGY.
WEDNESDAY, June 8th.—3.30 P.M., Mr. Leslie Paton: Optic Atrophy.
Fee for Post-Graduate Course £7 7*s*.
C. M. HINDS HOWELL, Dean.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Turner-street, Mile End, E.
Courses of Lectures:—
A Course of Fourteen Lectures on Psycho-Neuroses, to be given by Dr. M. Culpin in the Clinical Theatre of the Hospital. Open to *Students of* the Hospital and to Members of the Profession.
TUESDAY, June 7th.—5.15 P.M., Lecture X.: Diagnosis.
FRIDAY.—5.15 P.M., Lecture XI.: *Treatment.*
Advanced Lectures in Physiology, to Students of the University and to others *interested* in the subject.
A Course of Eight Lectures on Reception of Sensory Stimuli, to be given by Prof. H. E. Roaf in the Physiology Theatre.
THURSDAY, June 9th.—4.30 P.M., Lecture V.
SURGICAL UNIT.—A Special Course of Ten Lectures on Advanced Surgery in the Unit Theatre to Post-graduates and Senior Students.

TUESDAY, June 7th, and THURSDAY.—4.15 P.M., Mr. R. Howard: Diseases of the Breast.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND, at the Maudsley Hospital, Denmark-hill, S.E.

TUESDAY, June 7th.—4.30 P.M., Maudsley Lecture: Sir Frederick Mott.

UNIVERSITY OF LONDON.

Advanced Lectures to Students of the University and to others interested in the subject.

A Course of Three Lectures in Embryology on Recent Advances in Experimental Embryology, to be given by Prof. E. W. MacBride at the Imperial College, Royal College of Science, Exhibition-road, S.W.

TUESDAY, June 7th, WEDNESDAY and THURSDAY.—5 P.M., Lectures I., II., and III.

A Lecture in Medicine on Permeability in Physiology and Pathology, to be given by Prof. H. J. Hamburger at the Rooms of the Royal Society of Medicine, 1, Wimpole-street, W.

WEDNESDAY, June 8th.—5 P.M.

A Course of Four Lectures in Pharmacology, on Some Actions of Foodstuffs in the Production and Treatment of Disease, to be given by Prof. E. Mellanby at the Royal College of Surgeons, Lincoln's Inn-fields, W.C.

MONDAY, June 6th, and TUESDAY.—5 P.M., Lectures I. and II.

ST. BARTHOLOMEW'S HOSPITAL (UNIVERSITY OF LONDON), West Smithfield, E.C.

A Course of Eight Advanced Lectures in Physiology, to be given in the Physiological Laboratory, to Students of the University and others interested in the subject.

TUESDAY, June 7th.—4.30 P.M., Lecture VI.: Prof. E. H. Starling: The Heart in Exercise.

UNIVERSITY COLLEGE (UNIVERSITY OF LONDON), Gower-street, W.C.

A Course of Four Advanced Lectures in Hygiene to Students of the University and to others interested in the subject.

MONDAY, June 6th, and FRIDAY.—5.30 P.M., Dr. C. Porter: Recent Developments in Legislation for the Prevention of Disease. (Lectures III. and IV.)

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, June 9th.—4 P.M., Lecture:—Mr. Pitts: Oral Sepsis.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, E.

A Course of Post-Graduate Clinical Lectures and Demonstrations in the Board Room of the Hospital, free to Medical Practitioners and Students of Medicine.

MONDAY, June 6th.—Mr. N. C. Lake: Intussusception.

TUESDAY.—4 P.M., Mr. A. H. Todd: Common Disabilities of the Lower Limbs (other than Paralytic) in Children (II.).

THURSDAY.—4 P.M., Mr. B. W. Howell: Treatment of Injuries to the Elbow (with cases).

FRIDAY.—2.30 P.M., Mr. J. Taylor: Treatment of Anterior Poliomyelitis.

TAVISTOCK CLINIC FOR FUNCTIONAL NERVE CASES, 51, Tavistock-square, W.C.

A Course of Ten Lectures on Elementary Psychotherapy, to be given by Dr. H. C. Miller, at the Kingsway Hall, Kingsway, W.C.

FRIDAY, June 10th.—5.15 P.M., Lecture VI.: Mental Mechanisms: Conflict: Regression: Repression; Complete Formation: Transference; Compensation.

INSTITUTE OF PATHOLOGY AND RESEARCH, St. Mary's Hospital, in the Lecture-room of the Bacteriological Department.

A Course of Lectures on Pathological Research in its Relation to Medicine, open to all Members of the Profession and Students.

THURSDAY, June 9th.—4.30 P.M., Prof. H. Head: Release of Function in the Nervous System.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.

TUESDAY, June 7th.—4.30 P.M., Lecture:—Dr. W. F. Shaw: Malignant Disease of the Uterus.

Appointments

COATES, V. M., M.A., M.D., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Assistant Physician to the Royal United Hospital, Bath.

MCARTHUR, J., L.R.C.P., L.R.C.S. Edin., L.R.F.P.S. Glasg., Medical Officer of Health for Conisborough Urban Council.

ROBERTS, EVA, M.B., Ch.B. Manch., Medical Officer of Health (temporarily) for Isleworth.

WOOD, W. B., M.D. Lond., Assistant County Medical Officer, and to act as Tuberculosis Officer for Grays, Tilbury and Orsett.

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne District Infirmary.—Res. S.O. £250.

Bedford County Hospital.—Asst. H.S. £150.

Bethlem Royal Hospital, Lambeth-road, S.E.—Jun. Asst. Phys. £350.

Birmingham, Queen's Hospital.—Surg. Registrar. £100.

Birmingham University.—Demonstrator of Anatomy. £300.

Bradford Royal Infirmary.—H.S. £200.

Brighton, Royal Alexandra Hospital for Sick Children.—Hon. Anæsth. Hon. Radiologist.

Brighton, Royal Sussex County Hospital.—Three H.S.'s. Cas. H.S. and H. Anæsth. Each £120.

Bristol Royal Infirmary.—H.P., H.S., H.S. to Ear, Nose, and Throat Dept., Cas. O., and Ophth. S. Each £120.

Cardiff, King Edward VII. Hospital.—H.S. £200.

Charing Cross Hospital, Agar-street, W.C.—Phys. in charge of Children's Department. Asst. Phys.

Colchester, Essex County Hospital.—H.S. £200.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Asst. Phys.

Evelina Hospital for Children, Southwark, S.E.—Phys. to Out-patients.

Exeter City Mental Hospital.—M.O. £300.

Hackney Union Infirmary.—Jun. Asst. M.O. £414 16*s.* 10*d.*

Hull Royal Infirmary.—Asst. H.S. £150.

Leeds Infirmary, Beckett-street.—Asst. M.O. £100.

Liverpool Royal Southern Hospital.—Two H.P.'s and three H.S.'s. Each £100.

Liverpool Stanley Hospital.—Three H.S.'s. Each £120.

London Homœopathic Hospital, Great Ormond-street and Queen-square, Bloomsbury, W.C.—Two Res. M.O.'s. £100.

London Lock Hospital, 91, Dean-street, W.—Clin. Assts.

Manchester Royal Infirmary.—H.P. £50.

Ministry of Pensions, Birmingham Orthopædic Centre.—Jun. Res. M.O. at the Highbury, Uffculme, and Sorrento Group of Hospitals. £350 to £400.

Newcastle-on-Tyne, City Hospital for Infectious Diseases, Walker-gate.—Res. Med. Asst. £350.

Newcastle-on-Tyne, Hospital for Sick Children.—Jun. Res. M.O. £200.

Newport, Mon., Royal Gwent Hospital.—Hon. Radiologist.

Nottingham Children's Hospital.—Res. H.P. (female). Res. H.S. (female). Each £180.

Plymouth, Borough of.—Asst. M.O.H., £500.

Preston and County of Lancaster Royal Infirmary.—H.S. £200. H.P. £200.

Prince of Wales's General Hospital, Tottenham, N.—Hon. Asst. P. or S. to X Ray Department.

Queen Mary's Hospital for East End, Stratford, E.—Cas. O.

Rotherham Hospital.—Jun. H.S. £150.

Royal Dental Hospital of London, Leicester-square, W.C.—Two Hon. Anæsths.

Royal Free Hospital, Gray's Inn-road, W.C.—H.S. £50. Hon. Anæsth.

Royal Naval Medical Service.—Surg.-Lieuts. 26*s.* 6*d.* per diem.

Royal National Orthopædic Hospital, 234, Great Portland-street.—Res. H.S. £150.

Royal Waterloo Hospital for Children and Women.—Hon. Phys. for Out-patients.

Salford Royal Hospital.—Anæsth. £50. H.S. and Cas. H. S. Each £150.

Sheffield, Jessop Hospital for Women.—Asst. H.S. £100.

St. Helens Hospital, Lancashire.—Res. M.O. £250.

St. Pancras Hospital.—Asst. M.O. (female). £300.

Southampton Free Eye Hospital.—H.S. £200.

South Uist, Parish of.—M.O. and Public Vaccinator. £170.

Stamford, Rutland and General Infirmary.—H.S. £250.

Taunton, Taunton and Somerset Hospital.—Sen. H.S. £200. Jun. H.S. £150.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Sen. Res. M.O. £250.

West End Hospital for Nervous Diseases.—Asst. P.

West London Hospital, Hammersmith-road, W.—Two H. P.'s, H.S. Each £50. P. Neurologist.

Wigan Education Committee.—Female Asst. Sch. M.O. £500.

THE Home Secretary gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, for the Barnard Castle, Darlington, and Richmond County Courts in Circuit No. 2, and the Leyburn and Northallerton County Courts in Circuit No. 15. Applications for the post should be addressed to the Private Secretary, Home Office, and should reach him not later than June 22nd.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshops Acts at Walton-on-Naze (Essex).

Births, Marriages, and Deaths.

BIRTHS.

CUNNING.—On May 23rd, at Upper Wimpole-street, the wife of Joseph Cunning, F.R.C.S., of a son.

GOODWIN.—On the 30th May, at a nursing home, to Elsa Mary, wife of Aubrey Goodwin, M.D., a son (Timothy Rudhall).

HANCOCK.—On 28th May, 1921, at Trevaunance Cottage, Howe Green, Chipstead, Surrey, the wife of Allen Coulter Hancock, M.C., M.R.C.S., L.R.C.P., D.P.H., of a son.

SANDILAND.—On May 19th, in Shrublands Nursing Home, Croydon, the wife of Ernest L. Sandiland, M.B., B.S., D.P.H., of a son.

SHEPHARD.—On May 23rd, at Latymer House, Sheerness, the wife of Dr. Hopper Shephard, of a son.

DEATHS.

BEALY-SMITH.—On May 26th, at Manchester, Richard Leonard Bealy-Smith, M.R.C.S., L.R.C.P., aged 53 years.

WILLIAMS.—On May 29th, at Queen Anne-street, W., Campbell Williams, F.R.C.S., aged 62 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE ECONOMICS OF INFANT WELFARE.

A MEETING of the National Baby Week Council was held at Armitage Hall, Great Portland-street, London, W., on May 24th, when the reports of the Chairman of the Executive Committee and of the Hon. Treasurer were submitted and addresses read.

Dr. **ERIC PRITCHARD**, chairman of the Executive Committee, who presided, said that the three special phases of child welfare work, which the Council were emphasising this year, were (1) the importance of breast-feeding, (2) the urgent need for some scheme of pensions for civilian widows, and (3) the prevention of blindness with special attention to the infectiveness and treatment of ophthalmia neonatorum. It was hoped that the National Baby Week Council and the Health Week Committee would work in close coöperation. The National Baby Week Council would celebrate its fifth birthday from July 1st to 7th, but it had been suggested that combined Health and Baby Week celebrations might be held in the provinces and in Greater Britain in October.

Mr. **J. MARSDEN**, the hon. treasurer, said that subscriptions and donations were greatly needed. On the basis of last year's work about £450 would be required. There was a balance at the bank of about £150, and it was hoped that another £300 would speedily be forthcoming.

Economy in Life.

Dr. **MABYN READ**, medical officer of health for Worcester, then read an inspiring address on the successful efforts to improve infant life in the city over the health of which he presided. The population of Worcester in 1900, he said, was 48,000; it was now about 50,000. When he was appointed medical officer of health in 1891 the infant death-rate was 208 per 1000. During the first five years of the present century it was 145, in the next five years 121, from 1910 to 1914 it fell to 91, in the next five years it was 69, and last year the figures showed 67 per 1000. The three individual years previous to this—namely, 1917, 1918, and 1910—showed 64, 60, and 61 per 1000 respectively. Previous to the founding of the Infant Health Society in 1907 there had been no particular health activities, though some 200 of the worst houses had been removed—a small proportion in a total of about 11,000 dwellings. The Infant Health Society began with one health visitor, but in 1910 the city council gave a grant to the Society and two years later took over the health visitor as an official. A second health visitor was appointed in 1915. Though some classes for mothers were held, no clinics were started till 1917 when a lady doctor was appointed giving half her time to the clinic and half to school work. In 1910 the Society obtained a grant from the American Red Cross Society and established an antenatal clinic. During the progress of the Society milk was provided for mothers and children, and was now supplied by the city council. In 1913 dinners were given to expectant mothers, and a small amount of dental treatment was given; both these activities were limited by the finances of the Society. From 1910 onwards, at the classes for mothers, the infants were weighed. No difficulty had been experienced in obtaining a welcome for the health visitor in the homes of the poor, and an important factor in the progress of the work was the coöperation and sympathy of the midwives. When difficulties had occurred, Dr. Read said, he called the midwives together, when matters were soon smoothed out. Some 16 midwives attended about 80 per cent. of the births in the city. The prevalent opinion among the mothers now was that it was a disgrace to have an unhealthy baby. The good results had been almost entirely due to home visiting. At the present time there were four health visitors and an antenatal centre, which was kept constantly full by the recommendations of the midwives.

Economy in Efficiency and Economy in Health.

Miss **ELEANOR RATHBONE** (Liverpool) deplored the lack of provision made by the State for babies, motherhood not being recognised as work of public importance. The poverty period of the ordinary working-class family came just at the time when the mother was bearing children, and this had most serious effects upon the race. Nothing could be more wasteful or more extravagant than the present system of neglecting mothers and children. Was it not about time that the nation should recognise that its baby crop was as important as its wheat crop?

Dr. **LEONARD HILL** said that health, including the health of the baby, was bound up very largely with the question of coal. With our wasteful methods of using it only about 5 per cent. of its energy and heat value was utilised, the other 95 per cent. polluting the atmosphere and setting up conditions which caused ill-health and dirt. We were now experiencing the benefits of unobscured sunlight as a result of the coal shortage, and he instanced the advantages of sunlight and fresh air as seen in the results to tuberculous children in Alpine climates, where they ran about covered with only a loin cloth. The effects upon these diseased children were extraordinarily good. If this life and open air schools were good for the diseased the same conditions should be good for the healthy. In London he believed there were only two open-air schools, while in New York there were 120.

Prof. **E. L. COLLIS** said that economy consisted in spending money wisely and well, and that it must not be confounded with parsimony. By a long series of enactments during the past 100 years, the country in the interests of economy had been nationalising the care of health. The first test of spending money wisely was the return on expenditure. On the credit side was the productive activity, mental and physical, of the adult members of the nation. But the results of nationalising the care of health had not as yet produced the most economical results. In order to obtain a healthy nation the first need was healthy babies. The standard of health of children at birth was fairly satisfactory and it ought to be maintained and improved. Girls in schools should be taught mother-craft. Money spent on health visitors was true economy. It was cheaper to spread a knowledge of fresh air and cleanliness than to patch up casualties in sanatoriums and dispensaries.

In a short discussion which followed, reference was made to the need for better housing conditions, and for supplying children with milk in the interests of sound teeth.

UNITED STATES ARMY RATIONS.

IN the April number of the *Military Surgeon* Major C. C. Mason and Capt. A. T. Shore speak of the work done in France by the officers of the Food and Nutrition Section, American Medical Corps, attached to the Division of Laboratories and Infectious Diseases. These were staff officers who considered whether the men got good meals regularly, and if not, what was wanted—whether more food, better food, better distribution, better cooking, or better mess equipment. Much bread was at one time lost from an epidemic of mould, and this was looked into. Meat was supplied to the army "in better condition than to the average American home." It was difficult to arrange that all men should get rations, for on Monday demands were sent in, but not till Wednesday were the rations received, and meantime 30 new men might have joined; but eventually the telephone minimised this difficulty. There were mess sergeants who saw to the drawing and the storage of rations, serving of food and prevention of waste, but it is noted that these sergeants should not be chosen merely because they are unfit for other soldierly duties, and that cooks, too, should not be selected in the companies on the sole ground that they are flat-footed men. In an appendix there is a statement of the various rations served out to American

soldiers. We print above the ordinary daily or "garrison" ration, the "field service" ration, and the "travel" ration drawn by men doing little work in troop trains.

The authors of the paper suggest that commanding officers might, with advantage, take greater interest in their cooks and kitchens—"men fight only once in a while, but eat *three times a day.*"

THE EVIDENTIAL VALUE OF CERUMEN.

IN the future it will be the mark of a clever criminal to throw dust, not into the eyes of the police, but into his own ears. Dr. Severin Icard[1] has shown recently that among the trade marks borne infallibly, if unintentionally, on the bodies of industrial workers must be counted the dust adhering to the cerumen in the external auditory meatus. It appears that the most careful toilet will not remove all traces of a man's past environment, but only the use of a small instrument for curetting the meatus, and even so, the operation is not without considerable risk in unskilled hands. Moreover, it is easy to imagine that a completely wax-free ear might prove in itself a cause for suspicion on the part of an examining counsel. Even the alternative method of concealment which we have indicated might well fail under the searching investigation of the technique devised by Dr. Icard. Specimens of wax are examined by him both quantitatively and qualitatively, both under the microscope and by chemical tests; it might well be that a lead-miner who had filled his ears with coal-dust would fail in his deceit as much by the presence of an excessive quantity of coal as by the discovery of a contemporary layer of lead.

SARAH GAMP OF ARABIA.

THOSE who lament the existence of unqualified midwives in England may derive some measure of consolation from the reflection that in some other parts of the world conditions may be even more cruel. It would be difficult to find sadder stories in all the annals of child-birth than those told by Doctor Thierry-Detaille, of Bizerte, in the May number of *Tunis Médical*. He teels first of a primipara, aged 18, to whom he was called by the patient's sister. It appeared that after the girl had been in labour three days her native attendant had confessed her inability to do any more. The doctor recognised by her feverish appearance that the attempts made in these three days had not been without their malign results. The temperature was 101° F. and the pulse 130. Vaginal examination discovered a fœtal head, firmly engaged, with the cranial vault completely denuded. The dead child was delivered by forceps, and it was then seen that a portion of the scalp as large as a five-shilling piece had been torn from the child's head. The family stubbornly refused to allow the young mother to be taken to a hospital, so she remained in the care of the Arab attendant until she died a fortnight after her first-born. His second story is of another native "midwife" who considered that a prolapsed cord was a heaven-sent aid to help her extract the baby. In this case the mother, who was a 3-para, survived, but the child was of course killed. There is room in North Africa for a lot of health propaganda.

THE CARE OF MENTAL DEFECTIVES.

THE training and after-care of mental defectives was the subject of discourse by Dr. F. R. P. Taylor, medical superintendent of the Hellingly Mental Hospital, at the annual meeting, held at Brighton on May 18th, of the Guardianship Society. Dr. Taylor considers that all mental defectives should receive some training in establishments specially set apart for the purpose, and believes that with suitable training a very large proportion of mental defectives could be made at least partially self-supporting. Provision for the future could be made in two directions: (1) by a central colony—preferably attached to a special school—where, after attaining a certain standard, children should be boarded out in cottage homes with foster parents, and attend daily at a central block of workshops; or (2) by the methods employed by the Guardianship Society. The latter scheme had many advantages, and most nearly restored the child to homelike surroundings. The work of the Society was of real benefit, not only in providing for the happiness and welfare of the individual mental defective, but also for the protection of society and of the race.

The Guardianship Society provides for the supervision of the mentally defective: (1) by boarding out in carefully chosen families; (2) by assisting them to obtain training and employment suitable to their capabilities; and (3) by visiting them and taking a friendly interest in their moral and material welfare. The Society's record for the year just ended shows that the fresh applications made during the year numbered 358, compared with 243 in the previous year. The number of fresh patients actually taken was 185, against 156 last year. 360 patients were cared for as against 445, and the number remaining at the end of the year was 206 as against 184. Two patients were removed from institutions and put under guardianship, and one patient was transferred from an asylum to guardianship. The committee considered this was particularly satisfactory as justifying the view of the Society that certain cases were better suited to this method of care than to institutional treatment.

During the year 46 cases had been under supervision in their own homes at the request of the Brighton corporation, and four certified patients had been entirely self-supporting, thus saving at least £200 to the ratepayers. At the present time the Society had 20 patients entirely, and 32 patients partially self-supporting.

HUGH MORTON (UNREGISTERED).

AT the Marylebone Police-court on May 9th, Hugh Morton, of Park-lane (formerly of 15, Cavendish-place), appeared to answer three summons under the Venereal Diseases Act, and one summons under the Medical Act, issued against him at the instance of the Medical Defence Union, Limited. The facts upon which the prosecution relied were admitted by the defendant, and the magistrate after hearing counsel, and without calling witnesses, imposed a penalty of £30 in respect of each offence under the Venereal Diseases Act, and £20 in respect of the offence under the Medical Act, with 5 guineas costs on each summons; and sentenced the defendant to two months' imprisonment in default of payment of the fines and costs within seven days.

HYGIENE IN THE KINEMA.

As the result of the activities of a local health society, the sanitary condition of local kinemas has been under review by the East Ham Borough Council. An opportunity was afforded us of inspecting the new Coronation Cinema at Manor Park, London, E., prior to its formal opening by the Mayor of East Ham on Saturday, May 28th. It is a large and airy building, seating 2000 persons individually, wide aisles, and a number of exit doors providing means for rapid emptying in case of need. Ventilation shafts are arranged for the inlet of cooled air in summer. The aim of the managers to provide healthy conditions under which entertainment can be enjoyed has been successfully carried out.

Lettsomian Lectures

[ABRIDGED]

ON

SURGERY OF THE LUNG AND PLEURA.

Delivered at the Medical Society of London on Feb. 7th and 21st, 1921,

BY G. E. GASK, C.M.G., D.S.O., F.R.C.S. ENG.,
SURGEON AND DIRECTOR OF SURGICAL UNIT,
ST. BARTHOLOMEW'S HOSPITAL, ETC.

(WITH COLOURED PLATES.)

[THE first lecture was devoted to an outline of the treatment of chest wounds from the beginning of the 14th century—when the science was raised by Theodoric, the Italian, and Henri de Mondéville from the obscurity which had surrounded it since Roman times—to 1914. The lecturer referred to the "Grande Chirurgie" published by Guy de Chauliac in 1363; to the decline of Western European learning, including medical and surgical knowledge, during the Hundred Years' War; to the appearance of gunshot wounds after the introduction of the arquebus in the 15th century; and to the renascence of surgery in the 16th century under Ambroise Paré, Gale Wurtz, and Peter Lowe. Coming to the 18th century, the work of John Hunter was discussed and linked up with that of Guthrie and Baron Larrey during the Napoleonic War. Mention of the Crimean campaign, the American Civil War, and the Franco-German War, led on to the "antiseptic era," when the work of Pasteur and Lister, and substitution of the pointed bullet for the leaden ball, rendered surgical conditions much more favourable in the Boer, Spanish-American, and Manchurian wars. It was pointed out that in earlier times improvements noted in one century were often forgotten in the next; that treatment during two periods—the 14th century and the beginning of the 19th—was exceptionally good; and that in the latter particularly, when knowledge of bacteriology and anæsthetics was still non-existent, a remarkable state of efficiency was nevertheless attained to by the medical services of the British and French armies during the closing stage of the Peninsular War.]

LECTURE II.*—TREATMENT OF WOUNDS OF THE THORAX DURING THE WAR OF 1914–19.

The treatment of wounds of the chest with which we started at the beginning of the recent war, and which gradually evolved, may be taken, in a measure, as the effect on us of the experiences of our predecessors. The most recent war of any magnitude which affected British military surgery had been the South African War. We saw how in that campaign the mortality from chest wounds was the lowest on record and that owing to the character of the weapon used—namely, the high-velocity low-calibre rifle—the wounds were, on the whole, not very severe, and commonly did not require active surgical treatment. At the commencement of the late war, therefore, surgeons began with the assumption that the wounds would be more or less of the same character, and that the best treatment for chest wounds would be to leave them alone unless an empyema should form, in which case a drainage operation would be performed. This belief that operative measures were unnecessary is probably the main reason for the lack of surgical assistance provided for men suffering from chest wounds; for a long time, however, the fear persisted that handling a wounded lung might re-start bleeding, and that a wide opening of the chest and formation of a pneumothorax might cause death.

In addition to all these reasons, military exigencies in the early days of the war would not allow of anything like active surgery being performed in close proximity to the front line. The wounded men had perforce to be evacuated to hospitals at the base, where they often arrived too late for anything but conservative treatment. Acting on the assumption that active surgical treatment would be harmful, rather than beneficial, a statement of methods of procedure advised was drawn up for the use of medical officers and published in 1915 in the official Memorandum on the Treatment of Injuries in War.

For purposes of comparison with the treatment adopted in previous wars, the following passages from this Memorandum may be quoted as a summary of the treatment:—

> "No doubt many men shot through the chest die in a few minutes, but of those who live long enough to reach a field ambulance or a clearing station the great majority recover. . . . The most important treatment of all is absolute rest in the recumbent or semi-recumbent position. . . . If the opening in the chest be large, so that air passes in and out during respiration, the skin around should be painted with iodine, and the opening of the wound firmly closed with antiseptic gauze covered by strapping. . . . A third of a grain of morphia should be given subcutaneously as soon as possible. . . . The presence of hæmothorax is rather to be taken as an indication for non-interference . . . it is to be accepted that tapping a hæmothorax is never to be practised in the early days after a wound of the lung."

For empyema resection of a portion of rib and drainage of the pleural cavity were advised. It was considered best that missiles retained in the chest should not be removed, unless they lay loose within the pleura and gave rise to pain and discomfort.

UNFORESEEN SEVERITY AND INFECTION OF WOUNDS.

Unfortunately the hopes of a humane war engendered by the experiences of the South African campaign were not realised. None of those who witnessed the arrival in this country of the first convoys of wounded will forget the dismay and consternation which accompanied the realisation that the wounds were severe and lacerated and almost all suppurating. Later, as the war of movement was replaced by trench warfare, wounds from shells, bomb, and trench mortar, and all the inventions of modern warfare became common, with the result that surgeons had entirely to re-cast their ideas of treatment, and the whole character of medical administration had to be remodelled.

THE MORTALITY OF CHEST WOUNDS.

One of the hardest things to arrive at is the actual mortality of chest wounds, yet both from the administrative and surgical aspect it is very important to understand the problem to be faced, which is only now being arrived at. The fatal cases may be considered under three headings as occurring:—

(1) On the field of battle; (2) in the forward medical units; (3) in the base medical units.

Deaths on the Battle-field.—There can be little doubt that the mortality of chest wounds on the battle-field was very high, although at first sight it was not expected. Medical officers working in field ambulances and casualty clearing stations saw how good was the recovery of a large proportion of the men who had been shot through the lungs and they naturally inclined to the belief that in most instances it was not a very serious matter to be hit in the chest. This view, however, neglected a very high mortality in the field. No figures on this point were collected in the British service. On the German side, Sauerbruch gives records of 300 dead examined on the field, and states that 112 of them (or 37 per cent.), were wounded in the chest. A very similar figure, 29 per cent., was recorded by Löffler for 469 dead on the battle-field in the Danish War of 1861, and in the New Zealand War of 1863 there was a 50 per cent. mortality. It is therefore probable that not less than one-third of those killed in the field had been shot in the chest. When one considers that the chest, roughly, is one-third of the target offered, it is probable that the figure given is approximately correct.

---

* Lecture III. will appear in the next issue of THE LANCET.

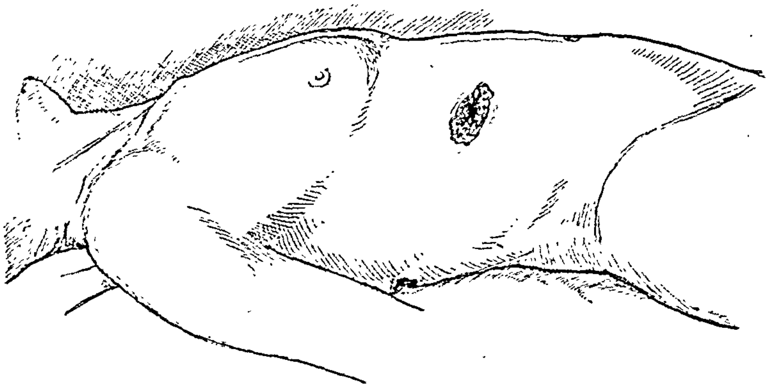
Deaths in Forward Medical Formations.—The mortality rate among the wounded who survived to reach medical units is now pretty accurately known. In the field ambulances it amounted to 7 per cent. and in the casualty clearing stations to 15·9 per cent.

Deaths at the Base.—The figures at the base hospitals are still more accurate. The figures remained pretty constantly at 6 per cent. It is therefore clear that of the men hit in the chest and who survived the battle-field about 30 per cent. died subsequently as the result of their wounds. These figures make one wonder whether the question of the provision of some form of protective armour for the chest should not be considered.

It is evident from what has been written that the mortality from chest wounds in the last war was considerable, and that an effort to reduce the mortality and invalidism of men surviving the field of battle was highly desirable. The problem which presented itself to the surgeon was, firstly, to investigate the morbid anatomy of chest wounds and to find out the causes of death or prolonged invalidism, and, secondly, to study the means of cure.

The opportunity for work of this sort did not present itself until the latter end of 1916, when the fighting on the Somme was dying down and surgeons were no longer delayed with a mass of urgent cases and had sufficient leisure to think and investigate. By this time also vast improvements in the medical services had taken place; hospitals well equipped with good nursing sisters, excellent operating theatres, and the best of instruments had been established close to the front line, so that the wounded were received a few hours after injury and—what was equally important—could be retained sufficiently long to allow proper investigation and observation. There were also facilities for making post-mortem examinations, and good physicians, pathologists, and radiologists were ready and willing to coöperate. In addition the heads of the medical services were eager to encourage and afford every facility for any investigation likely to be of service to the wounded men.

FIG. 1.



Drawing of a perforating shell wound in the right lower costal region. The entry wound behind was slightly smaller than that of the exit in front, but both were large and lacerated. Operation performed 12 hours after the wound.

PATHOLOGY OF CHEST WOUNDS.

It is not possible in these lectures to do more than point out the important aspects of the morbid anatomy of chest wounds; the latter have been described in greater detail in the official Medical History of the War. The wounds inflicted could broadly be divided into three classes: (1) those caused by rifle or machine-gun bullets; (2) shrapnel balls; and (3) portions of shell, bomb, or grenade. The proportion of each class of wound varied with the type of action. In open moving actions wounds by rifle bullets preponderated; in trench warfare the number of those caused by fragments of shell was much greater. Wounds due to shrapnel balls were few, and in the late phases of the war almost disappeared.

Wounds due to rifle bullets commonly perforated the chest and passed out, often drilling a small hole and doing comparatively little damage. These proved the most favourable class and are comparable to the wounds observed in the South African War.

Wounds due to fragments of shell (Fig. 1) were the least favourable, for the jagged fragments made large holes, splintered bones, lacerated tissues, and were prone to carry with them fragments of dirty clothing which provoked sepsis. It was soon found that the causes of death in casualty clearing stations could be divided roughly into two classes—those occurring within the first 36 hours after injury, and those occurring later.

The casualties occurring early were almost entirely due to the severity of the injury, combined with shock and loss of blood; and those occurring later—including those in base hospitals—were almost entirely due to sepsis of the pleural cavity or of the contained viscera. Further, the cause of prolonged invalidism following chest wounds was due almost entirely to infection of the pleural cavity and its sequelæ. (See Figs. 2, 3, 4, Coloured Plates.) Thus the problem which confronted the surgeon in dealing with chest wounds was the same as that of all the other wounds—namely, the immediate saving of life from shock and hæmorrhage and the prevention of sepsis.

CHANNELS OF INFECTION.

Granted that the chief danger to a man who had survived the first severity of the wound was infection, it became necessary to see how organisms reached the chest cavity. There were two main routes: (1) a direct introduction by the missile or by portions of clothing or equipment carried in by it, and (2) through the wound in the chest wall. A wound which opens directly into the pleural cavity, and through which air is constantly sucked, always leads to infection, and unless dealt with is often fatal. Further, unless adequate treatment is given to a wound even of moderate dimensions, through which air is not being sucked, it may suppurate in the course of a few days; and if the thoracic cavity is not sealed off organisms gain entrance to the pleural cavity, where they find the blood a convenient medium for growth. This accounts for many cases which exhibit septic changes only after an interval of five or six days. The principle, therefore, to be aimed at is early mechanical cleansing of the wound (both of the chest wall and of the injured viscera);

DESCRIPTION OF COLOURED PLATES.

FIG. 2.—Posterior view of a gunshot wound of the lung with hæmorrhagic extravasation and a wound in its lower lobe caused by indriven rib fragments, one of which (indicated by a dotted line) remains in the lung. The upper lobe is bruised and on its surface is a large subpleural bleb of air that has escaped from the torn pulmonary tissue. From a patient who died six hours after a non-penetrating dorsal wound of the chest by a piece of shell which passed tangentially from the right tenth rib behind to escape over the angle of the left scapula.

FIG. 3.—Thoracotomy performed 14 hours after a gunshot wound had been inflicted. The picture shows the chest widely opened and the lung pulled out by means of Duval's forceps. The lung is collapsed, wounded, and infiltrated with blood.

FIG. 4.—Perforating shell wound of the chest in the right lower costal region (from the same case as Fig. 1). Picture showing the injury when the splintered ribs had been removed after an incision joining the entry and exit wounds. The diaphragm has a tear 6 inches long and the liver shows radiating fissures with extensive laceration. The diaphragm was sutured and the chest closed. The patient died from shock 20 hours later.

GUNSHOT WOUNDS OF THE CHEST AND THEIR TREATMENT.

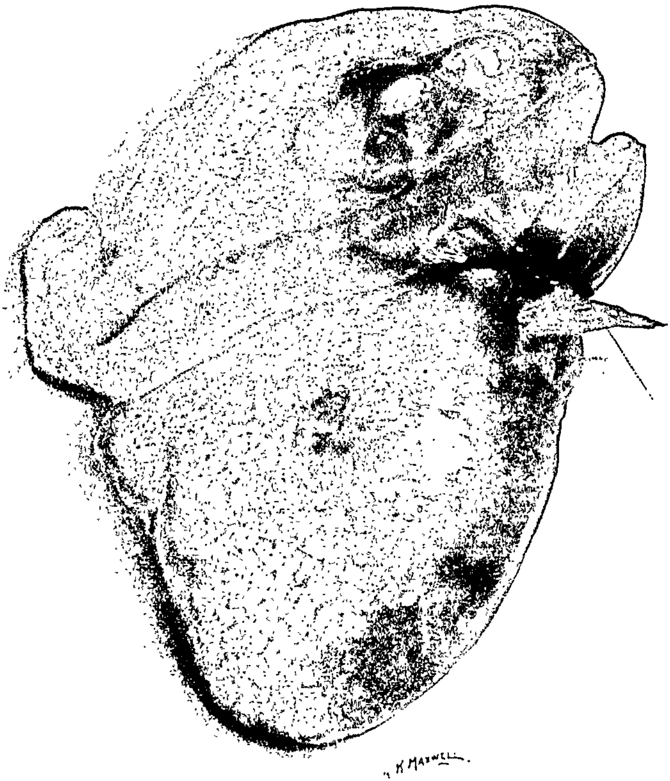


Fig. 2. The Wounded Lung.

GUNSHOT WOUNDS OF THE CHEST AND THEIR TREATMENT.

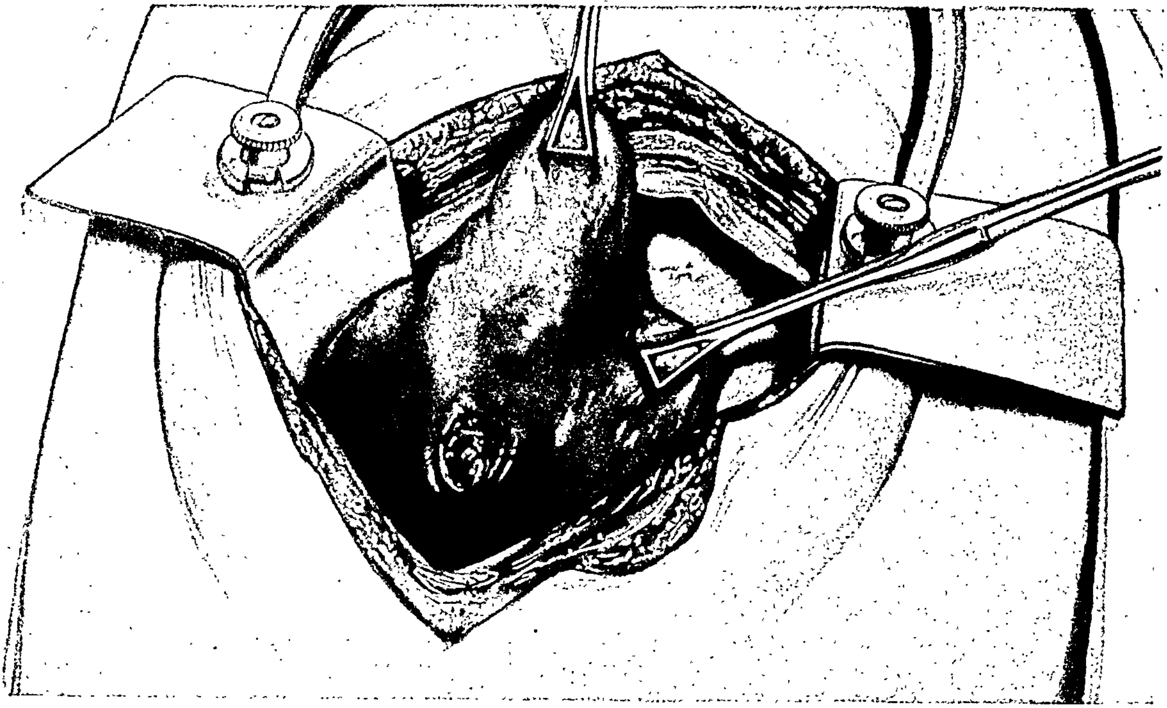

Fig. 3. The Chest widely opened.

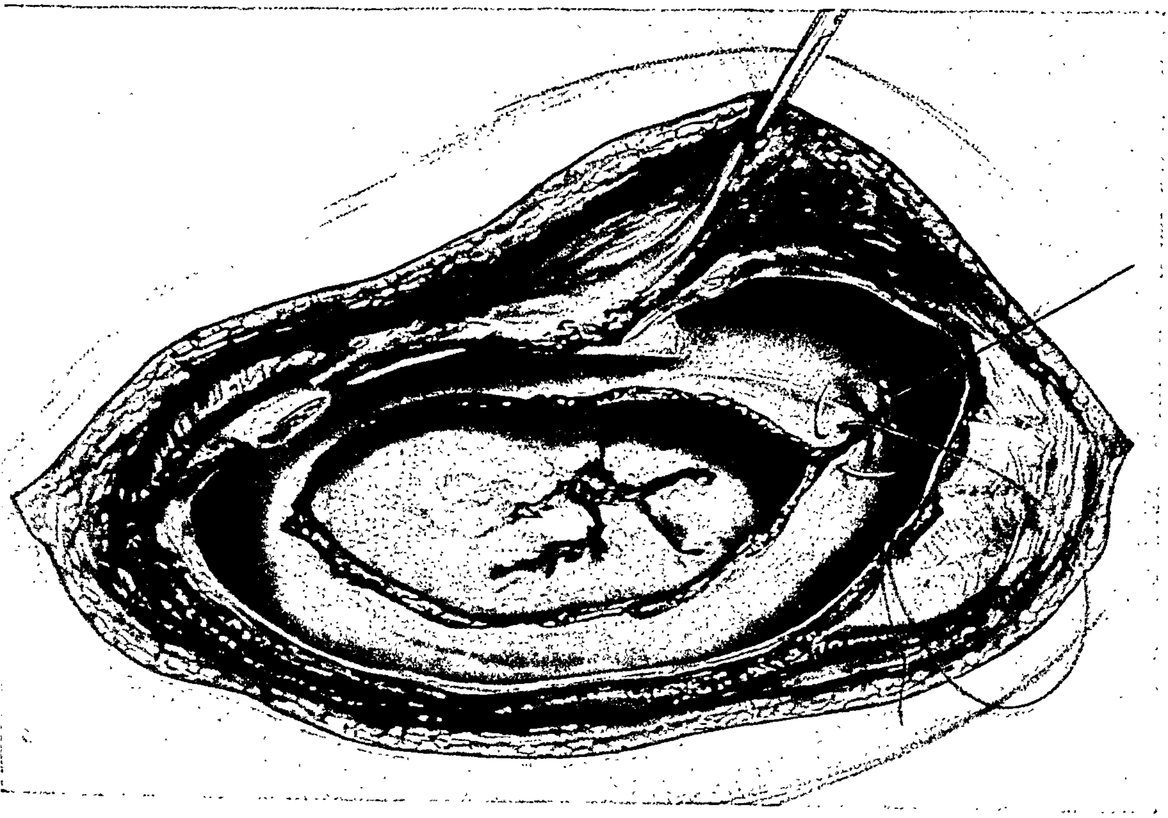

Fig. 4. Repair of the Diaphragm.

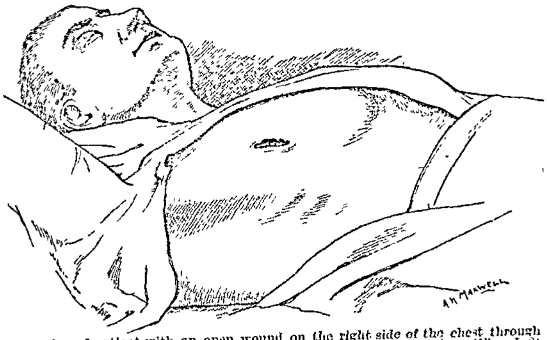
evacuation of all foreign bodies and of effused blood from the pleural cavity; repair or suture of the damaged lung, and closure of the chest cavity by suture.

It has been demonstrated with absolute certitude that the correct treatment of a contaminated wound, in order to prevent infection and suppuration in that wound, is a mechanical cleansing carried out a few hours after the injury before organisms have had time to grow and infect. This is attained by excision of the damaged and devitalised tissues, and removal of all foreign bodies, followed by early closure of the wound either by primary or delayed primary suture. The establishment of this principle is a far-reaching truth and is the greatest contribution made to military surgery in the late war. It results from the knowledge of anatomy, physiology, and pathology and is applicable equally to wounds of the extremities, head, abdomen, or chest. Many of our predecessors, especially in the Napoleonic wars, did great work, but the knowledge of bacteriology was denied them, and so they were unable to attain the results which were achieved by surgeons in the late war. The application of this great truth to wounds of the chest was not arrived at in one step; it was only little by little that we groped towards the light, and when we recall our early efforts to cure grossly suppurating wounds with highly-coloured strong antiseptics, and how we stated that surgery was put back to the pre-Listerine period, it seems as if we had been extraordinarily short-sighted and stupid. It is customary to exhibit a mild amusement at the quaint practices of our forefathers, but did not we forget much more than they forgot?

FIG. 5.



Drawing of patient with an open wound on the right side of the chest through which air was being sucked in and out. The series of drawings (Figs. 5–8) shows stages in the thoracotomy performed on this patient 15 hours after infliction of his wound.

OBSTACLES TO CHEST SURGERY.

As has been mentioned before, surgeons attempting chest surgery were at first troubled by two apparently large obstacles. The first was the dread of opening the chest, under a general anæsthetic, lest the resulting pneumothorax should cause a fatal respiratory failure; and the second was the fear lest manipulation of a recently-wounded lung might start uncontrollable bleeding. If the principle of mechanical cleansing of the wound was to be carried out, then it was necessary that a wide opening in the chest should be made so that the thoracic viscera could be brought into view.

Anæsthetics.—Prior to the war, the inclination of surgeons tended towards the use of some form of pressure chamber or intratracheal insufflation apparatus when it became necessary to open the pleural cavity. It was evident that such an apparatus was impracticable in the field and a very few trials with the ordinary anæsthetics proved at once that, at any rate under conditions then prevailing, a patient could be anæsthetised and one pleural cavity could be opened widely without any grave danger. As a matter of fact, patients with thoracic wounds bore operation well and took an anæsthetic satisfactorily, and we found it unnecessary to consider a pressure chamber. My own predilection was for the use of chloroform, either by itself or combined with oxygen, given through a Shipway's apparatus. The French used ether; the Americans, when they came in, used gas and oxygen, and many British surgeons employed local anæsthetics. It is therefore evident that the anæsthetic problem is not a difficult one. One of the bogies which hindered progress was therefore killed.

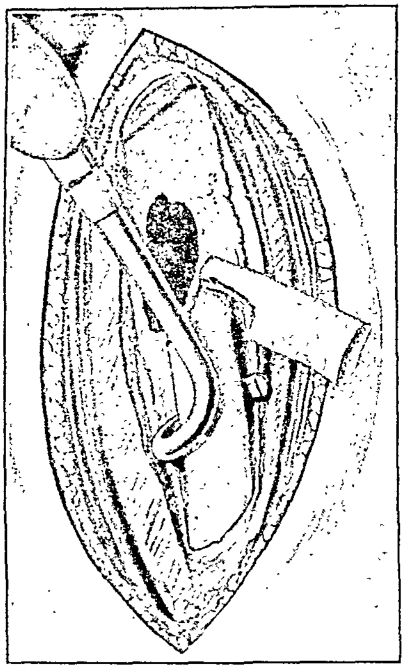
Manipulation of Wounded Lungs.—The other great fear—that handling of a wounded lung might re-start a serious bleeding—also vanished, for it was found that such manipulation was easy, was not attended by a serious fall of blood pressure, and did not cause bleeding. Once these difficulties were removed the way to advance was clear, and it remained only to decide which were the correct cases to operate on, and to devise the best routes of access to the thoracic cavity and the necessary technique.

SELECTION OF CASES FOR OPERATION.

It appeared obvious that a certain proportion of patients would get well without any operation, and equally obvious that a certain number required surgical treatment, either to save their lives or to prevent a long and severe illness; there was also a large intermediate class in which opinion might be divided. The sort of case which appeared most to require assistance was the man with a large open wound with fracture of ribs and a retained missile. Such cases almost invariably did badly on account of sepsis. Many died, or if they did not die, developed an empyema which seriously affected their convalescence.

It was on such a case that I personally did my first big thoracic operation during the war. It was in the latter end of 1916, while the work was very much in the experimental stage, and curiously the subject of the experiment was a young Australian doctor, who was admitted with a large open wound over the lower part of the thorax and a retained missile. After consultation with the excellent and helpful physician who was associated with the investigation, operation was decided on. The patient was anæsthetised with chloroform, the wound opened up, about four inches of the broken rib excised, and the pleural cavity opened widely by means of a rib-spreader. In the cavity of the pleura was found a shrapnel ball, a bit of rib, and a large piece of khaki tunic. These were removed, the jagged ends of rib cut cleanly off, and the pleural cavity cleared of blood; then the chest was closed in layers, pleura to pleura, muscle to muscle, and skin to skin. To our great joy the patient did well; the wound healed by first intention and remained healed, the lung rapidly expanded, and the pneumothorax disappeared. There was no doubt that that man, if nothing had been done, would, even if he had lived, have had an empyema which would have invalided him for a long period and very likely have given him a lifelong disability. As a matter of fact, his convalescence was short, and he soon regained his unit; we saw him in 1917 and again in 1918 and were able to assure ourselves by his record of service and by clinical and X ray

FIG. 6.



The wound of the soft parts has been excised down to the broken rib, which is being lifted subperiosteally by Doyen's elevator; the wound through the parietal pleura is exposed.

examination that his cure was sound and permanent. This successful case made a deep impression on our minds and revealed the possibilities of thoracic surgery in the field which, though suspected, were not proved.

It is unnecessary to detail all the steps which led up to the practice which was in force in the British armies on the Western Front at the termination of hostilities. The results achieved were the outcome of the earnest work of many surgeons, who received the greatest assistance from physicians, bacteriologists, and radiologists; the value of the team-work, as witnessed in the British Expeditionary force, has made a big impression on our profession.

Simultaneously with the progress made in the British medical services, the most excellent work was being done by the French, and the name of that brilliant surgeon. Pierre Duval, whom we esteem as an Honorary Fellow of our College of Surgeons, must ever be associated with thoracic military surgery.

POSITION OF THE TREATMENT OF CHEST WOUNDS AT THE END OF THE WAR.

In order to demonstrate the changes which had been made in the treatment of chest wounds during the war, it may now be apposite to quote a summary which was published in the last "Manual of Injuries and Diseases of War," printed in 1918, as a guide to medical officers.

"I. Cases in which primary operation is indicated:—(1) A ragged wound of the soft parts; (2) compound fracture of ribs; (3) bleeding from the parietal wound and intercostal artery; (4) pain; (5) an open wound of the thorax through which air is pumped in and out of the pleural cavity; (6) retention of a large foreign body in an accessible position.

II. Cases which do not require primary operation:—(1) Small clean wounds, including through-and-through bullet wounds, without evidence of serious intrathoracic injury other than hæmothorax; (2) cases in which a missile is retained, which is only of a small size; (3) cases in which a missile, though of large size, is in a position difficult of access; (4) cases of uninfected hæmothorax.

III. Cases in which primary operation is contra-indicated:—(1) Shock and collapse, such as would be contra-indications for any surgical procedure; (2) Collapse of the opposite lung."

TREATMENT BY OPERATION. (FIG 5.)

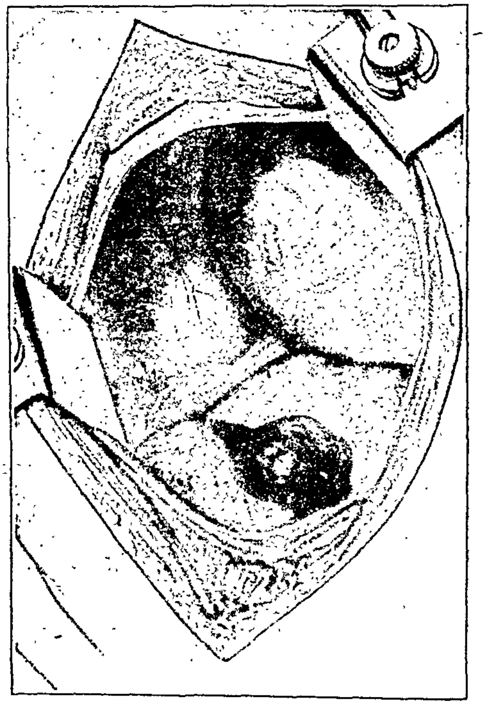
If an operation is to be done, it should be undertaken as soon as the initial shock of the injury has passed off and before sepsis has been established. After the lapse of 48 hours it is rarely advisable to perform any operation except for evacuation of an infected pleural cavity. It was found by experience that it could be undertaken usually about six hours after admission to a clearing station—that is to say, about 12 to 24 hours after receipt of the injury.

If nothing else be done, wounds of the soft parts (unless small and clean, e.g., rifle-bullet wounds) should be excised, because otherwise they will suppurate and infection may spread along the track of the missile, into the pleural cavity, giving rise to empyema. (Fig. 6.) Excision of the wound of the soft parts should be extended down to the ribs which are frequently broken. Whether or no further operation be undertaken for opening the chest, the splinters of bone should be removed, jagged ends of rib cut cleanly off, and all dead tissue excised.

Examination of the wound in this way may reveal either a bleeding intercostal artery or a large hole leading into the chest; a finger introduced into the pleural cavity may discover splinters of bone free or sticking into the lung. At this stage the case has been converted into one of open thorax; if it is decided not to open the chest further, the blood should be evacuated by rolling the patient on to the side, and then the thorax should be closed in layers—pleura to pleura, muscle to muscle, and skin to skin.

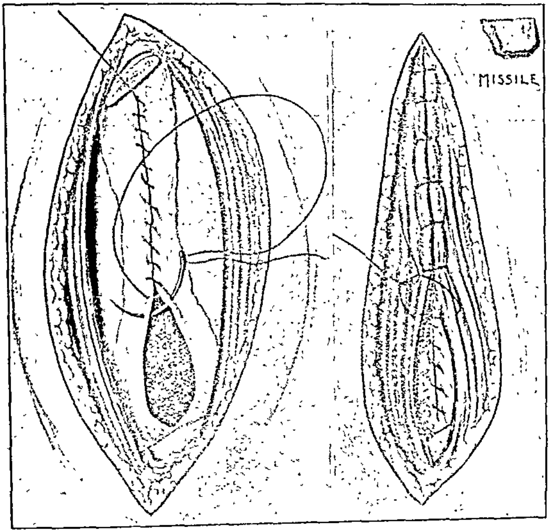
The importance of early closure of the chest cannot be over-emphasised: the relief given to the

FIG. 7.



The pleura has been incised in the line of the resected rib and the chest opened widely by means of a rib-spreader. The effused blood has been evacuated, giving a clear view of the diaphragm, in which there is a small injury; of the mediastinum, uninjured; and of the wounded collapsed lung. The hole in the lung and the rent of the diaphragm were sutured: the cause of the injury, a piece of shell, was removed from the pleural cavity and the chest closed.

FIG. 8.



Shows the first and second stages in the closure of the chest. First, the parietal pleura together with the periosteum of the rib is sutured; then the muscles, and finally the skin. The shell fragment removed from the chest is shown at the side. The patient made a good recovery without suppuration.

patient is immediate and great. Our ancestors discovered it as long ago as the 14th century, but it was forgotten time and time again. It was only on July 27th, 1917, that a memorandum was issued to the medical officers of the British Expeditionary Force calling attention to the value of the treatment of open pneumothorax by immediate temporary closure by suture.

THORACOTOMY.

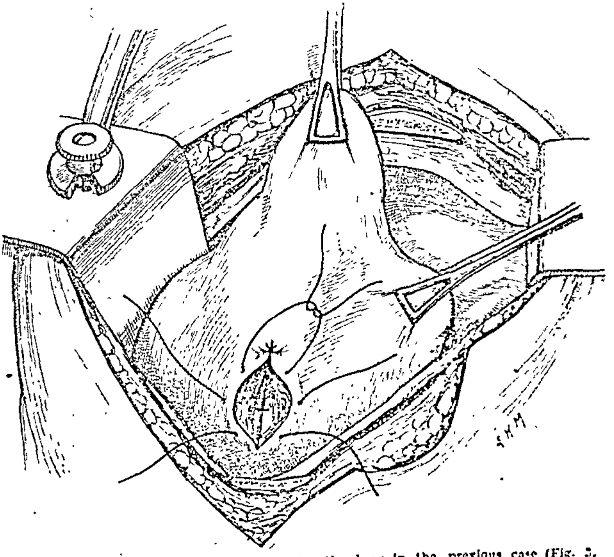
It is not difficult to open the chest sufficiently widely to allow of a complete examination of the lung and the pleural cavity. This opening may be made by excising about four inches of rib or by making an incision through an intercostal space and then inserting a rib-spreader, of which there are several efficient. The choice of route naturally depends upon the position of the foreign body relative to the wound of entry. Where possible, thoracotomy through the wound is to be preferred, for in any case the wound of the parietes needs to be excised and less damage is done to the chest wall by a single incision.

A missile may, however, lodge in the chest at a spot remote from the wound, and in such a case access has to be gained by a fresh incision. (Fig. 7.) The route that probably provides the best and easiest access is via the fifth rib in the mid or anterior axillary line, whence with the aid of a retractor or rib-spreader any part of the pleural cavity can be reached. With the chest thus widely opened the lung can be seen clearly and the foreign body may be visible; if the blood effused into the pleural cavity obscures the view, it should be remove by syphoning or mopping. If the foreign body is not visible (Fig. 8) it may be sought by inserting the hand into the pleural cavity, and removed through the wound of entry in the lung or by fresh incision into lung tissue. (Fig. 9.) Manipulation of the pleural contents can be done freely without dangerous fall of blood pressure.

TREATMENT OF WOUNDED LUNG.

Early operation, even within 12 hours after receipt of a wound, does not cause recrudescence of bleeding. Bleeding stops automatically when the

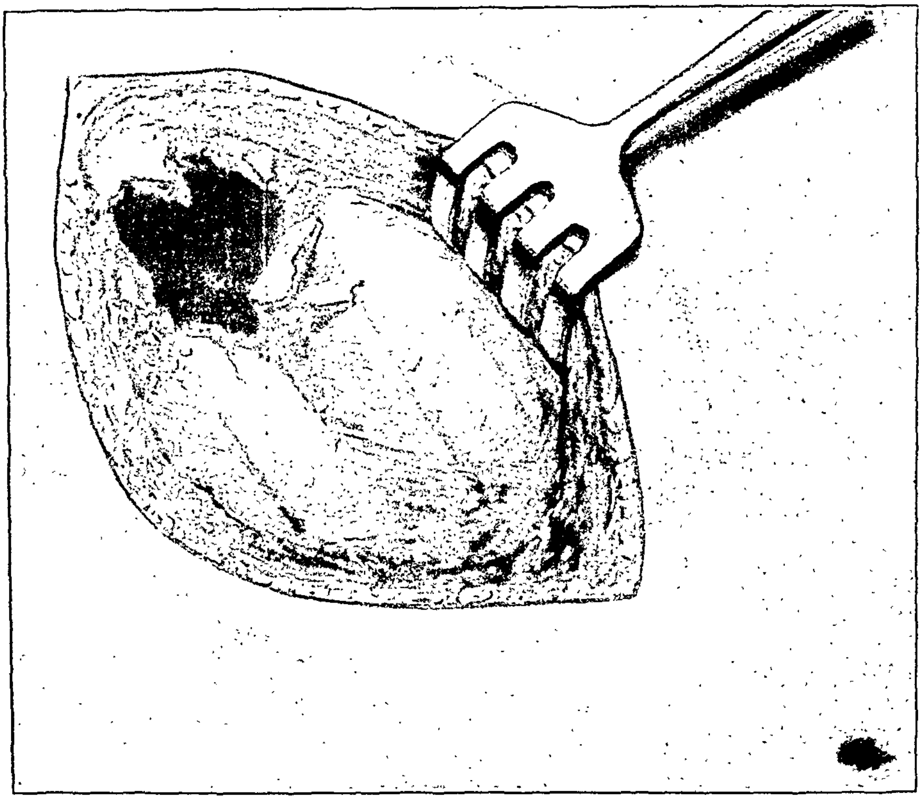
FIG 9.



Drawing to illustrate the method of suturing the lung in the previous case (Fig. 3, Coloured Plate), after excision of the wounded area. The patient recovered without suppuration.

lung collapses, unless a large vessel has been injured. Lung tissue may also be incised without fear; any fresh bleeding is easily controlled by suture. The treatment of a wound of the lung itself is sometimes difficult owing to the fact that it is undesirable to slit up a large wound so as to excise it. If the wound is readily accessible it should be excised, and if that is not practicable it should be cleansed as far as possible by wiping with gauze. (Fig. 10.) Luckily the lung is a well-aerated and vascular organ, apparently able to withstand a very considerable amount of infection. The proof of this statement lies in the fact that gas gangrene of the lung itself was of rare occurrence, though anaerobic infection of the blood in the pleural cavity was frequently met with. The hole in the lung is easily closed by suture and should be so treated. (Fig. 11.)

FIG. 10.



A perforating bullet wound with small entry and "explosive" exit. The destruction to ribs and pleura was great, and a large hole leading into the chest is revealed by the first stage of the operation.

Cleansing of the Pleural Cavity.—In all cases it is necessary to leave the pleural cavity dry and clean. The blood in it can easily be scooped out with the gloved hand and then the surface can be gently sponged. There is no objection either to washing it out with warm saline—the French use ether; but in any case it should be left dry and then closed.

Closure of the Chest.—Whether the operation has been performed through the wound or by fresh incision, the chest must always be closed completely in layers. In those cases in which there has been a loss of pleural membrane it may be impossible to bring the two edges together, and one has to content oneself with a covering of muscle and skin.

A large number of the patients treated in the manner just described made a good recovery, and in those patients who had lost a large quantity of blood recovery was aided by a transfusion of blood. Of course all the patients did not heal by first intention and a certain number of them developed an empyema which had to be drained later. A careful watch had to be kept to see that there was not an accumulation of fluid in the pleural cavity, and some surgeons adopted the principle of a daily puncture of the pleural cavity with an exploring needle, in order to keep the cavity dry. In this way they copied, but in an improved manner, the ancient custom of sucking the wound which was employed for so long in the earlier wars.

Such was the large operation which was developed for the treatment of a certain number of cases. For one reason or another, a very large group of cases were not operated on, either because there was not time or opportunity to do so, or because it was not considered necessary, and a considerable number of them became infected. It would be of great value if one could foretell which patient would become infected and which would not, for then one would forestall sepsis by an early operation. Unfortunately, one cannot do so, and all it is possible to say is that a patient who has lost a large quantity of blood is more liable to infection than one who has not.

TREATMENT OF HÆMOTHORAX.

Opinion has fluctuated as to the correct treatment of a patient suffering from hæmothorax without retention of a foreign body and without severe lacerated wounds—e.g., such as result from through-and-through bullet wounds.

Almost any patient with a penetrating wound had a hæmothorax to a lesser or greater extent. Very many men with clean perforating wounds and a small hæmothorax recovered quickly and returned to duty without disability in one or two months. Others with a large hæmothorax had a long convalescence and recovered with a disability of shortness of breath, due to fibrous thickening of the pleura and contraction of the chest; others again became infected and developed an empyema with all its well-known dangers and troubles. In the early days of the war it was not considered desirable to aspirate a hæmothorax for several days after the injury for fear of starting bleeding. This fear was found to be groundless, and with better knowledge it was clear that in any case of hæmothorax large enough to cause distress it was not only harmless to aspirate, but actually beneficial, and so this became the general practice. A few enthusiasts went so far as to urge that every case of penetrating wounds should be operated on, the hæmothorax emptied, and the chest closed. This appeared to be an extreme view which was not justified.

It remained, therefore, an axiom that a patient with a hæmothorax should be watched most carefully for signs of infection, so that with the first development of symptoms more active measures might be taken.

Treatment of Infected Hæmothorax.

Signs of infection of a hæmothorax developed sometimes within a few days of the injury, or might be delayed for four, five, or six weeks. In the late stages where pus had formed the only treatment to be done is a drainage operation. If, however, infection developed and was recognised within a few days after the wound, it was often worth while to make a wide opening in the chest, so as to clear out the whole of the hæmothorax fluid and the blood clot. In a few cases in which infection was mild it proved possible to close the chest completely without drainage, and in others a secondary closure was made after cleansing the pleural cavity for a few days with Carrel-Dakin fluid.

The success of the procedure in these cases seemed to depend more on the amount and character of the infecting organism rather than the surgery; in general terms, the method was not successful if the infection was due to streptococci.

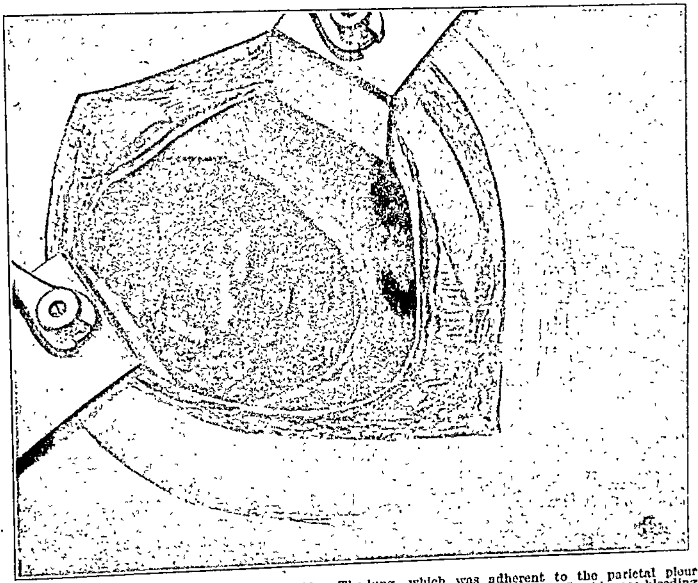
ABDOMINO-THORACIC WOUNDS. (FIG. 4.)

So far the subject has been considered as if wounds in the recent war were always single and confined to one cavity, as was more likely in days when men fought with sword and lance. Unfortunately this was not so, and surgeons who served with the armies must remember how often they were confronted with a man suffering from multiple wounds. A man might have a chest wound and a wound of the head, spine, or abdomen as well. Often, too, the same bullet traversed the abdomen and the chest, and these abdomino-thoracic wounds formed a dangerous and difficult class to deal with. If the intestines were perforated they had to be sutured to save life, and one had to weigh the advisability of operating on both the abdomen and the chest through separate incisions—unless it was possible to reach both through one incision, as sometimes occurred when the wound was in the lower left costal area. In doing operations in the pleural cavity one learnt how often the diaphragm was injured, and it was illuminating to realise how much easier it was to suture this structure from the superior rather than the inferior aspect.

LATE RESULTS OF CHEST WOUNDS.

Much might be said about the complications of chest wounds, of emphysema, of collapse of the lung, and a number of interesting phenomena. There is also a long chapter yet to be written on the after-results, such as the varying amounts of disability and the ultimate fate of retained missiles. Only by taking a broad view of the subject can one justly assess the results obtained.

FIG. 11.



Second stage of operation from the same case as Fig. 10. The lung, which was adherent to the parietal pleura, shows extensive laceration, and in this lacerated area are fragments of rib and visible lung vessels. In this case bleeding was still going on 23 hours after the wound, because the lung could not collapse on account of its adhesions. The bleeding points were ligatured and the chest then closed. The wound suppurated down to the lung, but the patient made a slow and satisfactory recovery.

If we may now presume to generalise, it may be said that progress has been made; but it is clear that this progress has been painfully slow, and neither steady nor continuous. It is also clear that at no time during the last 600 years has so great an advance been made as during the last war; the reasons for this advance are, broadly: The stimulus given to research by the large number of wounded, the fact that the medical services reached a pitch of excellence never previously attained, and the application to surgery of bacteriology, which supplied a rational treatment for wounds that was not understood by our forefathers.

The Relation of HEART DISEASE AND PREGNANCY.

By Sir JAMES MACKENZIE, M.D. Edin., F.R.S.,
DIRECTOR OF ST. ANDREWS CLINICAL INSTITUTE.

IN FOUR SECTIONS—SECTION II.

The Physiology of the Heart in Relation to its Efficiency.

Adaptability of the Heart to the Body's Needs.

The function of the heart is to supply blood to the body. The amount of work done by the heart is not constant, for it has to vary its activities according to the requirements of the different organs. The organs of the body vary in their activities. At one time they are functioning, at other times resting. The heart also varies its activities to meet these requirements.

The work of the heart is greatly facilitated by the modification of the function of other parts of the circulatory apparatus. Thus, during the activity of an organ the heart's output is increased, chiefly by an increase in the rate of its contraction; at the same time its work is facilitated by relaxation of the blood-vessels of the active organ. The heart itself receives a greater supply of blood during its increased activity. Starling computes that the amount of blood received by the heart during effort may be three times as great as that which it receives when at rest. This increased flow is rendered possible by the peculiar distensibility of the coronary artery.

Rest and Reserve Forces of the Heart.

The ability of the heart to accommodate its work to the requirements of the body is due to certain qualities inherent in the heart muscle. When the body is at rest the heart supplies just that quantity of blood which maintains existence. When effort is made it has the power of increasing its energy to meet the new demands. There are thus two forms of heart force: one, sufficient for the needs of the body when at rest—the rest force; and another, held in reserve, and used only when an effort is made—the reserve force.

While this distinction is somewhat theoretical, and is not sharply defined, yet the difference between the heart at rest and the heart during exertion is a very real one. Its importance will be made clear when we are considering heart failure.

Response to Effort in Health.

The healthiest heart can be forced to do only a certain amount of work; in other words, the reserve force is limited. Exhaustion of the reserve force is shown by signs of distress, particularly by dyspnœa. When effort is made the heart responds and continues to use its reserve force; so long as this is not exhausted, effort causes no distress. Thus, though individual may be able to walk a certain distance comfort, if he carries a heavy weight he will suffer distress before that distance is accomplished. His heart is not in any way impaired, but its reserve force is exhausted sooner.

Relation of the Reserve Force to Pregnancy.

This simple statement explains many of the phenomena which occur in the heart during pregnancy. We know that this state imposes more work on the heart, and this not only in connexion with the maintenance of the placental circulation, but also in respect of the additional weight carried by the mother. There are again disturbing factors in the form of interference with the shape and movements of the chest and displacement of the heart itself.

All this additional work is met by a call upon the reserve force. This is shown by the fact that the field of response to effort becomes limited; the pregnant woman cannot run upstairs so freely or so easily as was her wont.

Does the Left Ventricle Hypertrophy during Pregnancy?

The assumption that the heart hypertrophies during pregnancy is, as I have suggested already, not justified. To begin with, there is no need for hypertrophy so long as the reserve force is ample; as we shall see, when it is not ample, grave complications arise. Moreover, it is a mistake to imagine that a heart can hypertrophy in the easy fashion postulated. While it is possible that long years of continued severe effort may produce a slight increase in the size of the organ, this increase is so small as not to be perceptible in the vast majority of people who lead strenuous lives. It is a matter of observation that strong, healthy, vigorous men do not have larger hearts than men carrying on much less vigorous work. The fact that pregnant women are hampered by breathlessness in making some effort which previously they could undertake in comfort shows an earlier exhaustion of the reserve force. This does not suggest hypertrophy. Further, hypertrophy cannot be detected by a physical examination of the heart, except in those instances—for example, aortic regurgitation—in which it is very well marked. In such cases there is a big and forcible apex beat.

This forcible apex beat does not present itself in healthy pregnant women. The changes in the shape of the heart which occur are thus not due to hypertrophy. On the contrary we have a complete explanation of these changes in the displacement of the organ and the widening of the chest caused by the uterine tumour.

Relation of a Normal to an Impaired Efficiency.

The distress arising from an exhausting effort may not be due to disease of the heart, for distress can arise in health. This is well seen when any one becomes "winded" on running as far as he can. So that the phenomena of exhaustion are the same in quality in health and in disease. In health they appear more slowly, in disease more rapidly.

The distance which a healthy person can run is determined by the onset of distress. In the very young this distance is short; but with the years it gradually increases, until a maximum is reached in the hey-day of early manhood. From that period onwards a gradual decrease sets in, the distance ever diminishing, till old age is reached. There is no standard. Some people are remarkably long-winded; others, equally healthy, are short-winded.

The Purpose of Distress in Effort.

The purpose of the mechanism which thus limits for each of us the amount of effort we may undertake can fairly be described as protective; and it is well to keep this point of view in mind. It affords not only a measure of the heart's capacity, but also a rational line of treatment in heart failure. The mechanism is protective because of the universal dislike of distress. This dislike compels a man to cease effort before injury is done to his heart or other organs which are being strained. Little consideration, therefore, is required to understand how observation of the response to effort becomes the most important method of estimating the heart's efficiency. In eliciting this response we are calling into play a mechanism which exists in every individual, healthy and diseased.

The Standard of the Heart's Efficiency.

However, the doctor is to employ this method intelligently; and to do so he must undergo very careful training. The method is apparently so simple that everybody feels confident that he has recognised it, used it, and exhausted its possibilities. As a matter of fact, few people have given it anything like the amount of study it requires. In consequence its importance and the manner of its application are only partially understood.

The standard distance to be employed in determining whether or not an individual's response to effort is limited may at first seem a matter requiring definition. I have already referred to the fact that some people are long-distance runners, while others can run only a short distance. An amount of effort which would stop the latter may thus occasion the former no trouble. From this it can be seen that each has his own standard. It is therefore the duty of the doctor, by appropriate questions and tests, to obtain a knowledge of his patient's individual capacity, both in health and disease, before he attempts to determine the presence or the degree of heart failure. This information can be acquired only after much experience, as indeed may be understood when the various elements of the problem are taken into consideration. Thus, some people with damaged hearts can walk long distances but cannot cycle, while others can cycle but are distressed by walking. Some people, again, suffer speedily on walking on a cold day or after a full meal. One man with mitral stenosis and auricular fibrillation followed his occupation as a mechanic, swinging his fore-hammer many hours, but had difficulty when walking up a hill.

THE LAW OF HEART FAILURE.

The Response to Effort in Disease.

The first sign of heart failure is a diminution of the power of this organ to respond to effort. The heart, as we have seen, holds in reserve a force which can be liberated to meet the demands of the body. The exhaustion of this force gives the key to heart failure. All the organs of the body, being dependent on the heart for an increased supply of blood during their activity, show an impaired efficiency when there is any failure to supply their requirements. Thus the first sign of trouble will be found not in the heart itself, but in the other organs. Their functions will be interfered with and they will give rise to symptoms.

The Nature and Mechanism of the Early Signs of Heart Failure.

Bodily exertion is the most effective way of calling upon the whole reserve force of the heart. Exertion can be carried on at the command of the will; it employs great masses of muscles, and these require a great increase in their blood-supply during effort. While during exertion the muscles demand and receive an increased supply of blood, the other organs of the body have their blood-supply impaired. Their functions are thus not properly executed. Most of the organs afford no sign of impaired function; there are, however, organs which are extremely sensitive to a diminished or depraved supply of blood.

The failure of blood-supply occurs in two ways: (1) by an impairment in quality; and (2) by a deficiency in quantity. During continuous effort in health and in disease a time comes when the output of the heart diminishes so that the organs do not receive a supply of blood suited to their requirements. This diminished circulation through the cleansing organs results in an accumulation of waste products in the blood.

The consequences of this accumulation react upon all the organs, but there are two in particular in which symptoms of a striking and easily recognised kind are produced. The symptoms are so characteristic that we must set them down at once. They are: (1) breathlessness and its associated phenomena, in consequence of the stimulation of the respiratory reflex; (2) pain and its associated phenomena in consequence of exhaustion of the heart muscle. Both may not be present in the one individual, but one or other is always present, however slight the degree of heart failure may be. In advanced conditions other organs and tissues may show signs—for example, dropsy and enlarged liver; but these are late manifestations and are not constant.

Respiratory Distress.

The system most sensitive to an impaired blood-supply, or rather the system which most readily gives rise to sensations of distress, is the respiratory. Exactly how the distress is brought about need not concern us here; the point we are making is its association with heart failure. This is definite and beyond dispute. The impaired and impure blood-supply stimulates the respiratory reflex, so that the breathing is increased in rate. It is not, however, the rapid breathing which constitutes the distress, but that curious sensation called sometimes "air hunger," a feeling which compels the patient to take deep and rapid inspirations.

This breathlessness is the most common cause of distress in health and in disease. It is, in its quality, similar in both these states, as we have already suggested. Thus, a man in health runs a mile with ease, but suffers distress when this distance is exceeded; his heart becomes impaired, and then he may have the same symptoms of distress on running a few yards. With further impairment the breathlessness may come on during but a slight effort or even when he is at rest in bed. The reason for the breathlessness and distress remains the same in each instance. *It is the failure of the heart to supply* sufficient pure blood to the respiratory centre.

Pain.

The next most common distressful sensation which compels cessation of effort is pain felt in some part of the chest, usually on the left side, and in the left arm. The inquiry into the production of pain in affections of the viscera has been a long and difficult one. Indeed the subject is still somewhat confused. A certain advance has, however, been made, which shows that there are but few conditions actually capable of producing pain. One of these is the contraction—or at least a form of contraction—of muscle. It is now many years since my attention was first drawn to the fact that some of the severest pains are associated with hollow muscular organs—for instance, the uterus, the bowel, the ureter, and the gall duct. At a later period the study of heart affections revealed the fact that pain was evoked on occasions when effort was continued after exhaustion had taken place. This pain bore a relationship to the heart.

There is now sufficient evidence to show that, while the peristalsis or contraction of a hollow muscle may in many cases produce no sensation, contractions of a certain strength do produce pain. An analogy, too, exists between the production of this pain and that occurring in the skeletal muscles, for we find that, while the muscles usually contract painlessly, yet certain forms of contraction are very painful; for example, cramp. Moreover, if skeletal muscles be forced to contract when they are exhausted, or—an even more severe test—when they are deprived of sufficient blood-supply, then pain of so severe a character may arise that effort will have to be abandoned.

We find the same kind of pain arising in connexion with exhaustion of the heart. Conditions which enfeeble the heart muscle or impair its blood-supply favour the occurrence of pain when effort is made; and this pain is frequently of such severity as to cause a cessation of effort. The mechanism by which this effect is brought about is present in every individual, and the effect may be produced in the healthy as well as in those with impaired hearts. On several occasions I have noted its production in healthy people who had been exposed to great exertion for a long time; its production in damaged hearts is well known. From a study of a large number of cases, I conclude that pain arises from fatigue of the heart muscle, and is more easily produced when there is a deficient supply of blood to the muscle, as occurs in cases of disease of the coronary arteries. Its appearance in healthy people is due to fatigue from over-exertion. The pain may arise also in people whose hearts suffer, in company with other organs, from some general cause, as, for example, the poisoning from infection. I have dealt more fully elsewhere with the evidence which leads to this view of pain; I refer later to the matter under the heading of "The Neurotic Heart."

Mechanism by which Pain is Produced.

The following seems to be the mechanism by which pain and allied phenomena are produced. When a muscle is exercised beyond its power, exhaustion occurs; this acts by stimulating the nerve ends. These nerve ends convey to the central nervous system a stimulus which affects certain centres of which that giving rise to pain is one. The distress thus produced causes a cessation of the effort. The stimulation may affect not only the pain centres, but also other centres in the neighbourhood, such as the cells of nerves supplying certain muscles. In this latter instance the muscles contract, and thus we frequently find a sense of constriction as well as of pain.

Sense of Constriction.

There is, thus, a relation between the sense of tightness and the pain. In many of my cases of angina pectoris I have observed that the first consciousness of limitation of the field of response to effort is this weight or oppression or tightness across the top of the chest. The production of pain comes later. In some people effort produces first a sense of constriction; if the effort is persisted in, pain is induced. It is for that reason that I lean to the view that the compression of the chest is due to a reflex contraction of the intercostal muscles. The sensation sometimes goes so far as to cause a feeling that the chest is being gripped in a vice; this feeling resembles that accompanying the contraction of the intercostal muscles in pleurodynia, and also the hardening and contraction of the muscles of the abdominal wall in attacks of renal and gallstone colic.

It would seem, therefore, that, while the air hunger or breathlessness is produced by the defective supply of blood to the respiratory centre, the pain and sensation of constriction of the chest are produced by a defective supply of blood to the heart muscle, and therefore due to exhaustion of the heart muscle.

Relation of Symptoms to the Disease.

The question often arises: "Why do many people suffer from the same pathological state, and yet have symptoms so diverse?" We know that many people die of heart failure without having suffered any pain. From what I have said already the reader will be able to understand why I believe that this is to be explained by a reference to the sensation of distress which is first called into play. A defective supply of blood to the respiratory centre may cause such distress in the shape of breathlessness that effort ceases before the defective supply affects the heart itself. In the same way pain may be the first sign of an exhausted heart in those instances in which the blood-supply to the heart muscle is markedly diminished. This view is supported by what happens in some people who develop auricular fibrillation. In the great majority of people with this complaint breathlessness is the dominant symptom. It is produced by effort. Pain is much less frequent, and attacks of angina pectoris rarely occur. Patients who suffer from angina pectoris, and are compelled to abandon effort because of pain, sometimes develop auricular fibrillation. When this happens it is no longer pain which pulls them up, but breathlessness. Thus a man who could usually walk 200 yards before he was pulled up by pain developed auricular fibrillation, and was compelled to stop after 100 yards because of breathlessness. He had no more attacks of pain.

Exhaustion.

Inquiry into sensations which compel cessation of effort discloses the fact that there are several of these. Exhaustion is perhaps the next most important, though it is not directly cardiac in origin. It is the sensation which compels people in indifferent health to cease walking or exerting themselves—a feeling which probably everyone has experienced from time to time, and which each individual would describe in slightly different words. There are a number of different kinds of exhaustion; these can be provoked in different ways and are associated with different diseases. Into that I do not propose to enter here, further than to state that exhaustion is not a sensation provoked by a failing heart responding to effort.

This is important, because a sense of exhaustion is commonly assumed to be an evidence of heart failure. As a matter of fact the feeling is produced by another process altogether, which has as its basis a modification of the vaso-motor system. The fact that exhaustion may occur in healthy people as a temporary phenomenon and under circumstances in which no strain is put on the heart—for example, standing in a hot and stuffy atmosphere—proves this. An inquiry into the whole subject is at present being undertaken. I may perhaps say that the sensation is found to be a symptom of much significance, and that it seems to vary with the nature of the disease present. It may, of course, arise readily in people with some actual heart trouble; this, however, is a different matter from saying that it is due to the heart trouble. Its presence should invariably be regarded as a reason for the examination of the patient for some cause of ill-health other than heart disease, to which—let me repeat—its relationship is only incidental.

Palpitation.

The susceptibility of the heart to stimulation renders it liable to a variety of manifestations. There is scarcely a disease process, however trivial, or a modification of the activity of any organ, which is not reflected on some part of the cardio-vascular system; many of these disturbances affect some portion of the heart's own mechanism. It is on this account that we frequently encounter disturbances in the action of the heart when the body is at rest. As is well known, mental effort or excitement will produce an attack of palpitation. Moreover, experience shows that stimuli, from other organs, will produce the same phenomenon. When, therefore, we find a patient who complains of seemingly causeless attacks of palpitation, we should at once institute a search for the cause of these in some organ other than the heart: for it is rare, even in disease of the heart, for palpitation to arise without some extrinsic stimulus. I do not dispute, on the other hand, that certain states of the heart render it more liable to stimulation of this kind, and I mention in this connexion febrile or toxic conditions due to general infections or absorption from diseases elsewhere.

Summary of Heart Failure.

Evidences of heart failure are *to be found not in* the examination of the organ, but in the manner in which the circulation *is maintained in the different* organs of the body.

The symptoms of heart failure are *to be found* in the evidences of disturbed function of the organs of the body.

Such disturbed function is the outcome of an insufficient or depraved blood-supply.

While every organ of the body suffers when heart failure sets in, only *a few organs produce* recognisable signs.

Dropsy and enlarged liver are sometimes spoken of as "cardinal signs of heart failure," but they occur only in heart failure from certain diseases and in an advanced stage of the condition. Most cases of heart failure do not show these signs at all, or show them only at a late period.

The organs which show the most distinctive signs of heart failure are the respiratory organs and the heart itself.

Although the signs are provoked by these organs, they are not directly due to them, but to their reflex action on the nervous system.

In the case of both these organs heart failure gives rise to distress; in the one case the distress is associated with breathlessness, in the other with pain of a definite kind in a definite locality.

There are thus two groups of symptoms which are provoked by heart failure, and which afford a standard for measuring the heart's capacity.

HEART FAILURE WHEN AT REST.

Heart failure may set in when the body is at rest; when, that is, there are no opportunities for testing the effect of effort except movements in bed. This occurs in the case of people who are forced to lie up on account of an accident, or a surgical operation, or pregnancy, or acute febrile infections.

The symptoms of failure in these states resemble those of certain forms of chronic heart disease when the patient is confined to bed; for example, advanced mitral stenosis or auricular fibrillation. It is in these latter cases that the best opportunity is afforded of studying the condition.

In the inquiry I carried out I observed cases of typhoid fever, of old people confined to bed after a fracture of the leg or after a surgical operation, of pregnant women, and of chronic disease of the heart.

Earliest Signs.

The failure begins very insidiously, and unless carefully searched for it may easily escape notice until it is far advanced. The first symptom which arrests attention is a slight increase in the rate of breathing. A slight acceleration of the pulse usually accompanies the increase in the breathing. This, however, may be masked by an acceleration *of the* pulse due to the complaint.

Dilatation of Right Heart.

In certain cases, especially in *typhoid fever* or in chronic heart disease, there is an increase in the size of the right side of the *heart*, which is revealed by a slight extension of the transverse dullness, and by the appearance *of* pulsation in the epigastrium—a form of pulsation peculiar to the right heart.

In regard to these two signs, it must be noted that increase in the size of the right heart, of a mild degree, causes little increase of dullness to the right, because the right side of the *heart* is fixed by the attachments between the superior and inferior venæ cavæ. The increase pushes *the whole* heart to the left. In some cases, too, the greater part of the anterior surface of the *heart* is *made* up of the right auricle and ventricle. This can be verified by the character of *the apex* beat when it is present. When the apex is formed by the left ventricle there is an *out-thrust* during ventricular systole (Fig. 3), and an indrawing during diastole. When it is formed by the right ventricle, the reverse takes place; an indrawing occurs during systole and an out-thrust during diastole, as in the latter part of Fig. 3.

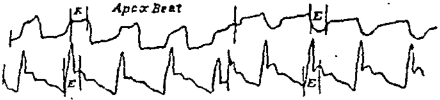


FIG. 3.—Simultaneous tracings of the heart movement (upper tracing), and *of the radial pulse (lower tracing)*. The first part of the upper tracing was taken from the apex beat, immediately outside the nipple line, and shows a rise, due *to the out-thrust of the apex*, during the ventricular systole (space *E*). This out-thrust is characteristic of the movement of the left ventricle. The latter part of the upper tracing was taken immediately inside the nipple line, and shows a fall during the period of the ventricular systole (space *E*). This indrawing is characteristic of the movement of the right ventricle—receding from the chest wall as it empties.

In *epigastric pulsation* due to dilatation of the right ventricle, the movements are similar to those of the apex beat, *when this is due to the right* ventricle—an indrawing during systole and an out-thrust during diastole (Fig. 4). That point distinguishes epigastric pulsation due to the right ventricle from epigastric pulsation due to other causes; for example the left ventricle, the abdominal aorta, or the liver—all of which show an out-thrust during systole. It is to be noted that this increase of the right heart may take place with no perceptible modification of the heart sounds.

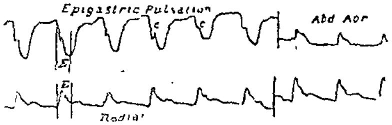

FIG. 4.—Tracings of the movements of the right ventricle in the epigastrium taken at the same time as the radial pulse. The epigastric pulsation shows an indrawing during systole (space *E*), due to the recession of the ventricle as it empties—resembling the latter part of the heart movement in Fig. 3. At the end of the tracing are two beats of the abdominal aorta, to show the difference between the epigastric pulsation *of the right heart and that of the aorta.*

Œdema of the Lungs.

The most instructive signs of early failure in bed, however, are *the changes which take place at the* bases of the lungs. The systematic examination of weakly people, *confined to bed, reveals frequently* a few fine crepitations at one or other base of the *lung*, behind. *In* the early stage of failure those crepitations disappear after the first deep inspiration. In many weakly people the condition goes no farther; in those, however, in whom heart failure proceeds, the crepitations do not disappear during deep inspiration, but persist. In course of time an impairment of the percussion note may be detected, and the condition may go on till there is marked dulness of one or both bases. Disappearance of the crepitations and the breath sounds now *occurs*. A post-mortem examination of such cases shows the lungs to be sodden *and airless at the base*. Sometimes patches of *catarrhal* pneumonia are found in the substance *of the œdematous parts* of the lung.

With the increase of this passive congestion other *symptoms appear*. The breathing becomes more hurried; the act of turning over in bed produces *evident* dyspnœa; the pulse-rate increases; if there be catarrhal pneumonia, the temperature *rises* with its onset, and the patient becomes manifestly ill.

Method of Detecting the Onset of Pulmonary Stasis.

It had been recognised that stasis of the lung tends to occur in cases of pregnancy complicated by mitral stenosis. Bearing this in mind, I extended my inquiry to include not only people with damaged hearts, but healthy women during pregnancy and people suffering from any form of debility. My object was to find out whether or not crepitations at the bases of the lungs are a sign of danger in pregnancy when they occur in a woman with heart disease. I examined and kept notes of women in the manner previously described.

I found by this means that crepitations at the bases of the lung are far from being an uncommon sign. The method I adopted was as follows: I told the patient to stay in bed on a particular day. When I visited her I observed which side she lay on, and before attempting any further examination made her sit up. While I auscultated the base of the lung on the side on which she had been lying, she took a deep breath. In most cases no crepitations were heard; in others fine crepitations were heard which disappeared after the first deep inspiration.

Such people went on to full time, were confined, and suffered from no heart trouble. Even those in whom the crepitations were more persistent did not have any cardiac trouble. In all of them the crepitations disappeared during the strain of labour, though many showed crepitations at the base a day or two after the delivery. No bad consequences followed. I noted, however, that the crepitations all disappeared on taking a few deep breaths.

In those women who had mitral stenosis or auricular fibrillation, and who gave trouble on account of their hearts, the crepitations did not disappear on deep breathing, but persisted. In some the lungs became dull to persussion from an increase of œdema. The œdema occasionally grew worse till the breathing became embarrassed; the œdema after confinement was often more pronounced than before it.

While, therefore, crepitations at the base, in a healthy woman, were shown to be a sign of no serious significance, they gave an indication of danger when the pregnancy was complicated by heart disease.

Mechanism of Right Heart Failure.

While in some people heart failure can take place and proceed far without demonstrable physical sign, in others œdema of the legs is a prominent feature. It is not quite clear why there should be this difference; personally I reasoned that dropsy is in some way or other associated with a diminished force of the left ventricle, and is, in all probability, due to a diminished *vis-a-tergo*. This view was strengthened by the observation that true cardiac dropsy is always associated with a dilated left ventricle.

I had frequently been confronted with cases of dropsy in which an abnormal sign such as a systolic murmur was present. I assumed that the dropsy was due to a failing heart. But I found that some of these cases showed no enlargement of the heart, and in the course of time it became apparent that their dropsy was not of cardiac origin. I therefore came to the conclusion that in all cases of *cardiac* dropsy the left ventricle is dilated, and so is not able to overcome the peripheral resistance. What other factors there are, beyond this, I do not know; nevertheless the recognition of an association, even if it be not cause and effect, is of great clinical value.

Reasoning from these facts, I looked upon the crepitations at the base of the lungs as being due to œdema, occasioned by a diminution of the force of the right ventricle. The association of œdema of the lungs with the demonstrable evidence of dilated right heart, already described, supported this view. I then set about to ascertain why it was that heart failure should set in while the body remained at rest, and why it should take this particular form.

When one reviews the factors which favour the flow of blood through the lungs, two of these stand out prominently:

(1) The force of the right ventricle;
(2) The movements of respiration.

The force of the right ventricle is the main factor, but the free movement of the chest wall undoubtedly helps. When a heart fails the patient sits up and breathes in a laboured fashion. When a person lies down pressure is exerted upon the ribs so that their movements are restricted.

With a good right ventricle there is no difficulty in maintaining the circulation through the lungs. With a weakened one, or with an embarrassed pulmonary circulation, the case is altered and the circulation is not maintained efficiently. The blood tends to stagnate in that part of the lung which is passive during respiration. This probably is the reason why the first signs of right-heart failure are the crepitations at the base of the lung on the side on which the patient lies. I have repeatedly seen all signs of stasis disappear when the patient was made to sit up and when, at times, he breathed deeply.

The fact that mitral stenosis hinders the flow of blood through the lungs, and therefore embarrasses the right heart, accounts also for the fact that œdema of the lungs is an early sign of the failure of the right ventricle. Having assured myself of this, I put the question why it should be specially serious in pregnancy. In order to find an answer, I made a careful study of certain changes which take place in a normal pregnancy. It is perfectly evident that in the pregnant state, towards the later months, the heart is embarrassed in healthy women; for the woman is not capable of so much exertion as she was accustomed to undertake, and becomes breathless during efforts which at other times would not have inconvenienced her.

Source of Danger in Pregnancy with Mitral Stenosis.

The embarrassment of the circulation which occurs during pregnancy was described in an earlier section, where it was shown that the growth of the uterine tumour interferes with the movements of respiration by widening the thoracic cavity, preventing the descent of the diaphragm, and displacing the heart. The result was seen to be a limitation of the heart's power to respond to effort, and a tendency to stasis at the bases of the lung.

In some cases of mitral stenosis the blood is obstructed at the mitral orifice, the left auricle becomes full and embarrassed, engorgement of the lungs occur, and the right heart has a difficulty in forcing the blood through the lungs. In mitral stenosis where this state of affairs is already present the additional embarrassment caused by pregnancy places the woman in a precarious state. This point, however, will be more fully discussed under mitral stenosis.

The Back-pressure Theory of Heart Failure.

The explanation given of the mechanism of heart failure in mitral stenosis has led to the idea that this is the usual manner of heart failure, and in consequence there has arisen what is called the back-pressure theory. Although, as I have pointed out, there is some truth in this theory in certain cases, yet in the majority it gives a wrong impression. With the discovery of murmurs, and their relation to valves found damaged at the post-mortem examination, there arose the idea that the embarrassment of the circulation in heart failure was due to the incompetency of the valves. This idea seemed to be strengthened by the dropsy and œdema of the lungs which were also frequently present. It was taught that where any difficulty occurred at the aortic orifice, the left ventricle would be embarrassed, and dilatation would follow. As a result of this dilatation, the mitral valve would no longer be able to close the orifice, so that during systole the blood would flow back into the left auricle. This in time would, in its turn, become distended, and so lead to interference with the pulmonary circulation and to engorgement of the lungs. The right ventricle thus must be embarrassed also, and would sooner or later dilate so that the tricuspid valves would be rendered incompetent and cause distension of the right auricle, and then engorgement of the veins of the body, enlargement of the liver, and dropsy. By some people to-day a tricuspid murmur is looked upon as a sign of complete heart failure.

It was on this plausible reasoning that the back-pressure theory of heart failure was built up; and it is because of this reasoning that murmurs are looked upon as being so ominous.

Seeing that this belief is so widely accepted by authorities and teachers, one might reasonably expect that, in the vast literature dealing with affections of the heart, there would be recorded at least one case showing the progress of heart failure after this fashion. I have searched diligently, but I have not found the record of one single case which could support the idea. Moreover, I have, time and again, asked its supporters to give me a record from their own experiences of heart failure arising in this way. None of them have done so. So long a period has elapsed since I first called attention to this misconception, that plenty of time has been afforded physicians to produce evidence in support of it. They have failed to produce any evidence.

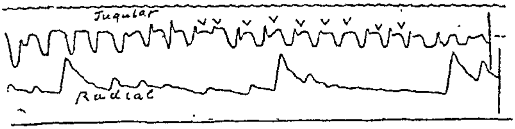

FIG. 5.—Characteristic irregularity appearing at the onset of auricular fibrillation. The upper tracing is from the jugular vein and shows large waves (*v*) with each systole of the right ventricle. The lower tracing is from the radial, and shows in addition to a marked irregularity that the beats are sometimes so small that the instrument fails to record them.

The reason why the erroneous view is held is that there are present in certain forms of heart failure marked evidences of engorgement; for example, congestion of the veins, lividity of the face, enlarged liver, and dropsy. These evidences are invariably pointed to as proofs of "back-pressure." But if one watches the onset of those symptoms, one will be able to perceive that they arise in another way.

The Mechanism of Heart Failure.

While watching for a period of years the changes which gradually occurred in my patients with mitral disease following rheumatic fever, and in elderly people, I was struck with the suddenness of the onset of heart failure in these subjects. It came accompanied by great breathlessness, lividity of face, enlargement and pulsation of the liver, and dropsy. During my observations I had taken notes of the various signs; on comparing the signs before and after the onset of heart failure, I found some remarkable differences. Thus, before the onset of heart failure the organ would be perfectly regular, while after the onset it would be irregular. The irregularity, too, was of a peculiar and distinctive kind.

Moreover, while before the onset of heart failure there were evidences of auricular activity, these disappeared with the onset. (These evidences of auricular activity were movements in the jugular veins or the liver due to contraction of the auricle, as in Fig. 2, and, in some cases, presystolic mitral or tricuspid murmurs. These all disappeared on the onset of heart failure.) These changes were afterwards found to be due to the occurrence of fibrillation of the auricle.

In some of my cases the auricular fibrillation lasted but a few hours or a few days. In a few, the patient, immediately after the onset of the fibrillation, became breathless. Some hours later the face would grow livid, the heart dilate, and the liver enlarge. The heart would sometimes suddenly revert to its normal, regular rhythm—the auricle beating again in a normal fashion. In these instances the patient at once experienced a great sense of relief, and in a few hours the face had regained its usual colour, and the heart and liver diminished in size. Effort would then be undertaken without breathlessness.

While I do not profess to comprehend the whole of the mechanism of heart failure, it is manifest to me that this sequence represents a very different picture from that which could be presented by "back-pressure." So far as I can understand it, the real process seems to be as follows: In cases of auricular fibrillation with heart failure the rate of the heart becomes increased, often greatly so, while the beats are weak and ineffective, and the radial pulse is small and sometimes scarcely perceptible (Fig. 5). The chief force which sends the blood through the systemic circulation to the right auricle is the left ventricle. When we find the ventricular beats small and ineffective, it is a reasonable surmise that such concomitant symptoms and signs as dropsy, enlarged liver, and lividity are due to the inability of this chamber of the heart to force the blood through the peripheral vascular system.

The inability of the left ventricle to expel its contents leads naturally to an accumulation of the blood in its cavity. Thus dilatation may occur. It is not, however, the accumulation of the blood alone which causes dilatation. In many hearts, in which fibrillation of the auricle is present, there is no dilatation. Dilatation indicates that the wall of the ventricle is damaged or impaired; its presence should always lead to consideration of the integrity of the heart muscle.

The importance of auricular fibrillation as a factor in the production of heart failure should be recognised. In my observations I found that about 90 per cent. of cases of heart failure with dropsy and enlarged liver were cases of auricular fibrillation. Moreover, in the great majority of cases of "heart-strain"—i.e. where heart failure with breathlessness has suddenly set in while the individual was making a violent or prolonged effort—the failure is due to the sudden onset of auricular fibrillation.

Auricular fibrillation is often attended by little or no impairment of the cardiac efficiency. In such cases the heart muscle is good, and the rate of the heart is not markedly increased.

There are other, but rarer, conditions which induce heart failure, but as they seldom, if ever, occur in connexion with pregnancy they need not be discussed here.

While "back-pressure" fails to account for the symptoms of heart failure, it is nevertheless a factor in some cases. In mitral stenosis there can be no doubt the left auricle is often embarrassed, and in some cases the pulmonary circulation shares in this disability. The right ventricle hypertrophies to overcome the difficulty in the pulmonary circulation. This point is of importance as it throws some light on the danger of pregnancy in mitral stenosis.

A MEDICAL FELLOW OF TRINITY COLLEGE, DUBLIN. Trinity College, Dublin, up to a few years ago elected one Fellow annually as the result of an examination in mathematics, classics, and philosophy. But under recent regulations it can, if it thinks fit, dispense with an examination and choose its Fellows where it will. The choice this year has fallen on Dr. W. R. Fearon, assistant to the King's Professor of the Institutes of Medicine, who has done much useful work in physiological chemistry. Apart from his work in science, Dr. Fearon's course in arts was distinguished. Among his honours is the vice-chancellor's medal for English poetry. Although Dr. Fearon is the first medical man for a long time to be chosen a Fellow, it has always been the custom for at least one Fellow at a time to devote himself to medicine subsequent to election. In former times the Board of Senior Fellows always included a *socius medicus*, and many who held this post were very distinguished in medicine as well as in arts.

THE SCHICK REACTION

AND DIPHTHERIA PROPHYLACTIC IMMUNISATION WITH TOXIN-ANTITOXIN MIXTURE.[*]

By A. T. GLENNY, B.Sc., K. ALLEN,
and R. A. O'BRIEN, M.D., D.P.H.

(*From the Wellcome Physiological Research Laboratories, Herne Hill, London.*)

The Schick reaction and diphtheria prophylaxis by active immunisation with toxin-antitoxin mixtures together constitute the greatest advance in our knowledge of the problems associated with diphtheria since the introduction of antitoxin. It is probable that when public opinion is sufficiently familiarised with these two methods and their significance, they will come into universal use and there will follow the same reduction in the occurrence of diphtheria that has been brought about by Jennerian vaccination for small-pox. Dr. Park of New York advocates the injection of all children between the ages of 6 months and 2 to 3 years. It is probable that the adoption of this method would lead in a very short time to the disappearance of diphtheria in the community. The methods are, therefore, of importance to those responsible for public health and to the immunologist.

We owe the intradermic skin reaction to Schick, and the active immunisation (which was foreshadowed many years ago by that prolific worker, Theobald Smith) to von Behring. Most of the work in this field has been carried out by von Behring and his colleagues in Germany, and by Park and Zingher in New York. It is a pleasure to acknowledge the generous manner in which Dr. Park and his colleagues have placed their material at our disposal.

Technique of the Reaction.

The Schick test consists in the intradermic injection of 0·2 c.cm. of a dilution of diphtheria toxin containing in 0·2 c.cm. 1/50 m.l.d. for a guinea-pig. The quantity of toxin actually used is about 0·0004 c.cm. of an ordinary aged toxin. When we use a concentrated toxin similar to one recently prepared by Dr. P. Hartley, we inject about 0·000 016 c.cm., which contains 0·000 000 02 g. of nitrogen.

Four types of reaction are shown: "negative" given by people with antitoxin in their blood; "positive" by those without antitoxin. The positive consists in a persistent red flush at the spot where the unheated toxin was injected, whereas no reaction appears where the heated toxin was given. A third group ("pseudo") give a reaction, but have antitoxin in their blood. These people respond to the injection of broth in which diphtheria bacilli have been grown, and which has subsequently been heated to 75°C. for 10 minutes. This heated toxin contains practically no "true" toxin; it produces no reaction in the skin of a guinea-pig and large quantities can be injected subcutaneously into guinea-pigs without harming them. The response given by these people is called a pseudo-reaction and is due to some unknown constituent. It is commonly stated to be due to bacillary protein, but we cannot find any authority for this statement and we propose to investigate the truth of it. The fourth group ("combined") consist of those who are sensitive to toxin and also to the "pseudo" constituent. At the site where the heated toxin was injected they show a reaction, while at the site where the unheated toxin was injected there appears a much larger reaction, which is the sum of the "true" toxin reaction and the pseudo-reaction. These people are not immune to diphtheria. (We are emphatically of opinion that in carrying out the test injection of toxin alone may lead to dangerous confusion. It is imperative that the control, heated toxin, be injected into one arm and the unheated into the other.)

The pseudo-reaction is rather puzzling. Park and Zingher in their very large experience have not found it in infants or young children whether immunised or not; it begins to appear at 5–10 years of age, and becomes much more frequent in adult life. If it is a specific response to the protein of diphtheria bacilli, then one would expect it to appear more or less in parallel with the immunity to diphtheria toxin, but it does not do so. It does not appear for certain in those who have had diphtheria and recovered, and who months later may have antitoxin in their blood. It does not occur in the babies either of those mothers who show a pseudo-reaction or of those who do not. One German observer records a series in which 10 of a group of 20 mothers showed pseudo-reaction, whereas none of the 20 babies did so. The cell sensitiveness is therefore not transmitted diaplacentally. The concentrated toxin referred to earlier unfortunately produced a pseudo-reaction, although its nitrogen content is extremely low. Ordinary toxin boiled for 30 minutes has produced a pseudo-reaction in one of us.

Preparation of Toxin for the Schick Test.

We have hitherto advised the issue of diluted toxin only for several reasons. There is an error in "filling" capillaries with toxin, as described by Zingher last year. We are of opinion that the clinician is liable to introduce an error in dilutions owing to the difficulty of getting the whole of a minute drop of toxin, which is about 1/50 of a c.cm., into the diluting fluid. Earlier in our work a batch of toxin diluted in the laboratory sometimes failed to pass our guinea-pig test. It is evident that the conditions must be very rigidly controlled, or the dilution of toxin will not be of standard strength. A serious mistake might arise if practitioners used weak toxin and, because of erroneous reactions, concluded that certain patients were immune and might be safely left exposed to infection—e.g., in a school epidemic—or, on the other hand, might be safely left without the injection of antitoxin though suffering from membranous sore throat. (Recent work makes us hope that we have succeeded in finding a stable dilution.)

We therefore make a toxin dilution each week and test it intracutaneously on normal guinea-pigs. We find the m.r.d.—i.e., the minimal dose that will produce a reaction when given alone—and also the dose that, when mixed with varying quantities of antitoxin, will give a reaction. Our current toxin dilution ready for the Schick test, when further diluted 20 times, causes a reaction in the guinea-pig's skin; 0·1 c.cm. when mixed with 0·0004 of a unit of antitoxin and injected intradermically, must also produce a definite reaction.

Stability of Diluted Toxin.—The details of tests presented show that the diluted toxin when kept at 0°C. undergoes practically no deterioration in four weeks, whereas after seven weeks a loss of about 30 per cent. in value is found. After seven days at 15°C. the loss in potency is just detectable, while after 14 days the loss is about 30 per cent. When kept at 37°C. the dilution deteriorated seriously in one day.

Reliability of the Test.

During the past few years we have tested some of the laboratory staff many times and have obtained consistent results. Park and Leete found in repetitions of tests on the same patients by the same observer a discrepancy of a few per cent. only. We were interested to observe that most if not all of these discrepant observations relate to patients who had been positive, and, later, became negative. We have experimental evidence that the very small amount of toxin present in the Schick test dose will produce an increase in the antitoxin concentration of the blood. The details of some experiments on rabbits show that five days after the injection of a Schick test dose the antitoxic content of the rabbit's blood had risen above the level at which the Schick reaction fails to appear in human beings. If the same effect, as shown, had been produced in human beings, the first Schick test would have given a positive result, whereas another test of five days or more later would have given a negative result.

---

[*] Read before the Pathological Section, Royal Society of Medicine, April 19th, 1921.

The Schick test is roughly quantitative. A positive reaction does not indicate the total absence of immunity. The test does not divide the population into black and white, but rather into those darker or lighter than a certain shade of grey. If Schick had originally determined on 1/500 of an m.l.d. instead of 1/50, it is practically certain that numbers of people who give a positive response to the present standard Schick would give a negative reaction with the weaker dilutions, and would be considered immune to diphtheria. Roughly speaking, people with at least 1/30th of a unit of antitoxin per c.cm. of blood give a negative reaction, while those with less than 1/30th, or with no antitoxin at all, give a positive reaction. As the result of clinical experience Schick decided that it was safe to assume that people with 1/30th of a unit were immune to clinical diphtheria.

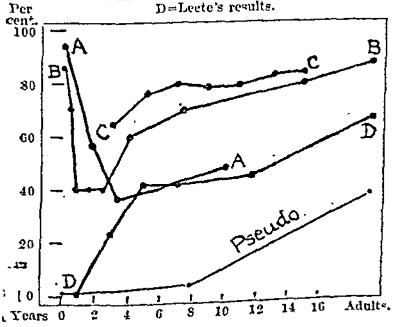
Results Obtained.

Recent observations on 18 members of the laboratory staff showed that 10 of them contained less than 0·0005 of a unit of antitoxin per c.cm. of blood—i.e., they probably contained none at all. Eight contained from one-fifth of a unit to 1 unit. Of these eight, six gave pseudo-reactions. Observations made from 1913 up to the present show that some of the laboratory staff have in their sera a greater concentration of antitoxin now than they had seven years ago. It was very interesting to find that three people, who had had abundant chance of becoming infected while working in diphtheria wards, gave positive reactions and had no antitoxin in their sera. It would appear that non-immune people may escape infection, and a suggestion arises that there may be some protective mechanism, bactericidal or otherwise, in addition to the antitoxin defence. There may be such an additional defence, but, on the other hand, we are told that in the history of infectious diseases hospitals many resident medical officers who have worked for years in diphtheria wards have assumed that they were immune, but have, later, succumbed to diphtheria. Our colleagues, presumably, did not suffer from the disease because they were fortunate enough to escape the implantation of bacilli on their mucous membrane.

The only clinical observations published in England are those made by Leete. His figures are of the same order as those of Park. Leete has published a series of observations in England. His results on patients over 4 years old, in the main, agree with the results of other investigators, shown on the graph. The discrepancies between Leete's observations on very young children are probably due to the smallness of the number of patients available. It may be that the differences in level between the curves obtained by Park and these other investigators are due to differences in population or to the use of a slightly different strength of toxin. We have some experimental evidence to suggest that the prescribed standard of "1/50 m.l.d. for a guinea-pig" may not be precise enough. We have not, however, completed our observations on this point.

Age Distribution of Negative Schick Reactions.

A=Schick's results. B and C=Park's results.
D=Leete's results.



Toxin-antitoxin Mixture.

The toxin-antitoxin mixture we have used complies with the American Government regulations. Although von Behring does not give the full details of his mixture, it is fairly certain, from the perusal of various German articles, that his mixture contains relatively more antitoxin than the American and ours. One would expect the antitoxin response of injected patients to be less than after the use of the American mixture, and so far as we can judge from the German literature, this is what is found. In 1 c.cm. of mixture, there are three L+ doses of toxin and about 3·5 units of antitoxin. A sample test of our current batch showed that three guinea-pigs injected with 1 c.cm. were all alive and well 30 days later, while of 17 guinea-pigs injected with 5 c.cm. of the mixture two died of an intercurrent disease (probably *B. Gaertner* infection) which was epidemic at the time, and 14 showed diphtheritic paralysis, most of them dying between the twentieth and twenty-ninth day. The injection of the toxin-antitoxin mixture into normal rabbits produced a satisfactory degree of immunity within 8–12 weeks. A quicker method of testing the antigenic suitability of a mixture consists in injecting it into a rabbit already possessed of a low degree of immunity. In one rabbit thus injected the concentration of antitoxin per c.cm. of blood rose from 0·004 units per c.cm. to 0·08 units four days later, and in six days to 0·5 units.

With regard to the period that elapses before an injected child becomes immune, it has been found that about 90 per cent. of children who have received three weekly injections of 1 c.cm. of a mixture give a negative response to the Schick test three months later. A negative response indicates a concentration in the blood of at least 1/30th of a unit of antitoxin. It is quite possible that a much lower content of antitoxin reached within a period of some weeks in the blood of a child who has been actively immunised recently would be sufficient to produce a considerable degree of protection against clinical diphtheria. Experimental evidence obtained by one of us (A. T. G.), and as yet unpublished, convinces us that the first minute amount of toxin conveyed into the system of the patient from the diphtheria bacilli that had gained a lodgment in the throat would produce an immediate and great increase of antitoxin in the patient's blood sufficient to neutralise further quantities of toxin produced by the attacking bacilli.

Conclusion.

Unfortunately we cannot bring forward a long series of results of the injection of toxin-antitoxin mixture. English physicians in charge of schools, institutions, and infectious disease hospitals have apparently been too busy up to the present to be able to investigate these two methods. In America the Schick reactions that have been carried out number many tens of thousands, and thousands of active immunisations have been done. The main purpose of this paper is to try to induce those who are fortunate enough to have large clinical opportunities to apply these two methods. We hope that some investigations may be carried out in London, for we believe that until much more experience has been gained in England, it would be very desirable for the laboratory investigator and the clinician to work in close coöperation. We may by working together succeed in explaining difficulties and discrepancies that are bound to be met with when new methods such as these are first used.

POST-WAR NEUROSIS.

By S. HERBERT, M.D., M.R.C.S., L.R.C.P.

There still exists among English psychotherapists a good deal of reluctance to recognise to the full the importance of the sex factor as a cause of psychneurosis. Though strenuous efforts are being made to find a substitute theory which will exclude sex, facts have so far proved too strong for such a procedure to have success. Even Dr. Rivers, who in his latest book attributes war neurosis to "a disturbance of the relatively simple instinct of self-preservation," admits at the same time that "the great majority of the neuroses of civil practice depend on failure of balance between the less simple sexual instinct and the very complex social forces by which this instinct is normally controlled."[1]

The cases recounted below add a striking testimony to the truth of Freud's sexual theory of neurosis, while incidentally furnishing an experimental truth of the oft-made observation that war tends to loosen the moral restraints, built up so painfully during civilised life. In our cases we have found that the return to the normal conditions of society, with its dull routine of conventions, led to an outbreak of a neurosis in persons who, in good mental health before the war, passed through the war itself in a most satisfactory manner. This kind of neurosis, in a sense a consequence of the war, being due to the sudden reversion of life from war to peace conditions, may be aptly described as post-war neurosis.

Case 1.—A professional man of 40 served in the Western Army during the war. He was extremely happy in his work there, and hated coming back to the narrow conditions of his civil life. As usual, he attributed his breakdown, which occurred shortly after his return, to overwork. His chief complaint was that he could not do his work. He was constantly afraid of committing gross blunders which would get him into trouble. The depression ultimately became so great that at times he seriously contemplated suicide, from which he was kept only by consideration for his wife. Though strictly moral in his sex relationships, he always felt himself to be of a somewhat frivolous temperament. This found plenty of outlet under the conditions prevailing in the war zone, without, however, leading to more than pleasantries and innocent flirtations. He masturbated in his youthful days, the sinfulness of which haunted him right through life. His wife, to whom he was devoted, is of a rather frigid temperament, and does not represent the type of woman who most attracts him sexually.

It soon appeared during the psycho-analysis that it was the repression of the sexual freedom enjoyed during the war that had produced the neurosis in the patient; and, indeed, the pursuance of the treatment on this line soon produced a remarkable improvement of the patient. He recovered his spirit and is now able to do a full normal day's heavy work.

Case 2.—A clerk, aged 30; was four years in the army, at the front 2½ years, being promoted from the ranks and serving as an officer to the entire satisfaction of his superiors. He felt very happy among his fellow officers and liked his army work very much. Though of a rather timid nature, he managed to "gulp down" his fear so completely that he became a successful leader of his men. He married at the beginning of his enlistment a girl he had known for years, with whom he is very happy. On his discharge from the army he was at a loss what to do, being disinclined to return to his old work which he disliked. Just as he was settling down to take up some new work he had to undergo a slight operation, which, though completely successful, interfered for the time being with his new profession. Thereupon he became frightfully depressed, feeling that he would never do any good again, that ruin was staring him in the face, &c. In this state he consulted me. Being always of a rather diffident nature, he now was convinced that he was "an utter good-for-nothing," who would never be able to look up again. He had lost all sex desire for his wife.

Here seemed to be a case where repressed fear might have been the cause of the neurosis. During the actual course of analysis, however, this soon proved to be fallacious. One of his earliest associations brought to light the fact that what weighed heaviest on his conscience was the circumstance that he had allowed himself to be tempted to have illicit intercourse at the front. Though this had happened "once, and once only," he felt in his own eyes degraded for ever. Strange to say, nevertheless, he felt that having always been as a boy of a sober and rather shy nature, he had not enjoyed life like other lads. The war had given him a taste of the lighter side of life among the officers which he missed very much on his return home. Further analysis showed that this was the complex which he had tried to repress with all his might since he had come back, and which had ultimately forced its way out in the form of an anxiety neurosis. Analytical elucidation of the conflict ultimately restored the patient to full health. His sexual desire for his wife returned and he lost all fear of the future.

Case 3.—A young tailor of 22, who had been in the army two years, but had never been to the front. He had been a shy, retired lad, not associating much with girls for fear of the harm it might do him. He never could get used to army life, felt lonely and homesick, and made, as he himself confessed, a very bad soldier. He kept well for some months after his demobilisation, but could not adjust himself to his previous work. He was suddenly seized with fits, which came regularly two to three times a week, especially towards night-time. The fits had, at first sight, very much the appearance of epileptic fits, though the possibility of their being hysterical was not excluded. Psycho-analytical treatment was recommended as holding out some prospect of cure, however faint. The success of the treatment entirely justified the advice given. Psycho-analysis soon revealed the sexual origin of the seizures. In the first place it transpired that the patient had given way to his sexual desires, inhibited so long during civil life, in no moderate degree. Always in fear of having to go to the front, he threw health scruples to the winds, thinking he would have "a good time" at any cost, and hoping, if he did break down, that it would at least save him from having to go into the trenches. Secondly, it became clear during the psycho-analysis that even in his youth his sexual desires had had the mastery over him; for though he did not actually associate with girls, he suffered from excessive sex phantasies which often produced a sort of stupor in him. Indeed, these states of mental absence were nothing less than the equivalents of sex indulgences. His fits proved to be merely the last extreme form of these mental absences. The repression he had had to exercise since his return to normal civil life—fear of consequences once more getting the better of him, as he now once more had "the will to live" in its normal form—led in its ultimate consequence to the fit as the unconscious equivalent of sex indulgence. Patient was completely cured of his fits, which so far, after 1½ years, have not returned.

What is characteristic about these cases is that in all of them sex repression was present before the war, without, however, leading to an actual neurotic breakdown of the patient. Life in the war zone tended to mitigate the condition of the patients rather than to accentuate it. They only broke down when the extended liberties enjoyed for the first time during the war had suddenly to be foregone once more with the return to civil life. This can only be explained on the assumption that the sudden repression of the temporarily released libido produced the neurosis according to the strictly Freudian mechanism.

Another case seems to point to the same conclusion. A working man, aged 40, came with a complaint of emissio præcox. He was married, and had suffered from the disease only since his return from the war. "Out there" he had taken things in a rather lax way, and he now found the restrictions of a monogamous life not at all to his taste. As the patient could not afford prolonged treatment, the case could unfortunately not be followed up.

Those who try to minimise the sex factor in neurosis should not forget that man's tendency is essentially poly-erotic. This poly-erotism must not be confused with polygamy. A man—and perhaps this also applies to a lesser or larger extent to women—may be married and truly devoted to his partner, and yet be full of other fancies.[2] It is when these become subject to strong repression that, under certain circumstances, they lead to the outbreak of a neurosis. It is the recognition of the sex factor which enables us to deal with such a neurosis in a satisfactory manner and effect a proper cure by means of psycho-analysis. Case 3 has an additional interest as showing that what appears to be epilepsy is often merely a masked hysterical fit which can be successfully treated by the psycho-analytical method.

HIPPURIC ACID SYNTHESIS TEST AS REGARDS THE FUNCTIONAL CONDITION OF THE KIDNEY.

BY P. L. VIOLLE,
MÉDECIN-CONSULTANT À VITTEL.

IN THE LANCET of April 17th, 1920, I stated in a letter that the study of hippuric elimination may give useful data as regards the functional condition of the kidney, and I wrote: "Hippuric acid elimination is profoundly influenced by diet. Hence it is necessary to base a test on conditions not dependent on the intaken food." The normal amount of hippuric acid having been estimated, we give the patient a dose of 0·50 g. of glycocoll and 50 g. of benzoic acid. From the time of taking the doses the total amount of urine is collected during 24 hours. The analysis should show an excess over normal of about 0·74 g. for 24 hours. Since the normal output for a healthy subject is about 0·40 g. the figures we should expect to find are somewhat as follows: 1·14 g.—that is, 0·40 g. the normal amount, and 0·74 g. the amount synthesised from the benzoic acid and glycocoll we have given. When the figure is lower, say 0·50, 0·40, &c., it may be asserted that the hippuric function is abnormal, and that probably there is some renal parenchymatous disorder.

Since my communication I have carried out researches to ascertain the relations which may exist between eliminations of hippuric acid and functional renal disturbances. In addition I have been desirous of proving to my satisfaction that the synthesis of hippuric acid is rather a function of purely renal origin, and in particular that it is not influenced by functional disturbances of the liver. The work is classified according to three clinical divisions of patients: renal, hepato-renal, and hepatic.

The following cases are typical examples:—

1. *Renal.*—Female, aged 20. Chronic uræmic nephritis for the last 10 years. Examination shows: albuminuria; excess of urea in the blood; blood pressure, max. 100 mm., min. 130 (Pachon). Ocular disturbances and constant headache for several years. Hippuric acid test: 0·10 g. instead of 0·74, the amount normally synthesised when 0·50 g. of benzoic acid and 0·50 g. of glycocoll are given. Second examination (a fortnight later), urea in the blood normal; blood pressure, max. 180, min. 120. No more ocular disturbances, no more headache. Therefore considerable amelioration of symptoms, except of arterial tension. Acid hippuric test; 0·27, instead of 0·74. Hippuric acid elimination: Jan. 4th, 0·18; 5th, 0·18; (test) 6th, 0·45–0·18=0·27; 7th, 0·18. The test of the hippuric acid synthesis shows that the state of the renal parenchyma is not ameliorated, and the blood pressure, always raised, is in ratio with the functioning of the renal parenchyma. The elimination of methylene-blue, when absorbed, lasts eight days.

Male, aged 60. Suffering from gout. First attack when aged 36. Feet œdematous. Big toes enlarged. Ulceration of and tophi in the feet and elbow-joints. Two attacks of gout a year for the last 25 years. General condition bad, never feels well, nausea, no sleep, no appetite; liver normal. Examination shows urine moderately abundant, no albuminuria, urea in blood normal; blood pressure, max. 250, min. 100.

Hippuric acid eliminations: Jan. 5th, 0·27; 6th, 0·28; (test), 7th, 0·27–0·27=0; 8th, 0·27. As in the preceding case the high blood pressure continues to be in ratio with the disturbances of the renal parenchyma, as evidenced by the hippuric acid test.

Male, aged 38. Arterial hypertension, without albuminuria, urea and chlorides normal; blood pressure, max. 200, min. 120 (Vaquez). Hippuric acid test perceptibly diminished, 0·59 g. instead of 0·74 g. Methylene-blue test similarly indicates that the kidney is slightly affected. Hippuric acid eliminations: Dec. 8th, 0·36; 9th, 0·38; (test), 10th, 0·95–0·30=0·59; 11th, 0·34. Thus the arterial hypertension is still in ratio with the renal disturbance shown by the test of hippuric acid synthesis.

2. *Hepato-renal.*—Male, aged 50. Admitted to hospital in state of coma. Generalised icterus, ammoniacal odour in breath, Cheyne-Stokes respiration, myosis, for many years slight signs of Bright's disease, urine scanty, some traces of albuminuria. Excretions of hippuric acid followed in the course of the attack, without the test of the synthesis being made, were as follows:—

	Azotæmia.	Hippuric acid.
1st day	1·81	0·25
2nd "	2·40	0·10
3rd "	2·14	0·10
4th "	2·66	0·08

There is a parallel between these excretions of hippuric acid and the retention of urea, and in the course of the acute attack the hippuric acid excretion forms a good index to the state of the kidney.

3. *Hepatic.*—Male, aged 40. Malarial subject and alcoholic. At the age of 31 he was treated in the colonies for enlarged and painful liver, with icterus and abdominal distension. Present state: alcoholic cirrhosis, emaciation, subicterus, liver enlarged and projecting four fingers width beyond the costal fossæ, hard and painful upon palpation; abdomen distended, no collateral circulation, no ascites, spleen normal. Urine normal in amount, no albuminuria, no sugar, urobilin in large amount, no bile-salts, urea 18 g., Maillard's coefficient 14 per cent. When Roch's test was carried out (absorption of 0·002 g. of methylene-blue by ingestion), after half an hour the methylene-blue appeared in the urine and persisted for 24 hours. Well-marked hæmoclasic shock following injection of milk (Widal). Consequently hepatic insufficiency. Hippuric acid test, synthesis completely effected 0·70. Hippuric acid excretion: Jan. 19th, 1·52; (test), 20th, 2·40–1·80=0·70; 21st, 2·08; 22nd, 1·85. The hepatic insufficiency has not therefore in any way affected the hippuric acid synthesis.

Summary.

1. The arterial hypertension is fairly closely connected with the renal condition so far as it has been possible to discover that condition by testing the hippuric acid synthesis in the cases under observation.
2. The azotæmia, chloridæmia, and albuminuria are evolved by crises. The modifications observed in the hippuric acid synthesis appear to be rather the reflection of functional parenchymatous disturbances that are capable of gradual modification.
3. The hepatic disturbances, since they are not accompanied by renal disturbances, fail to effect any modifications in the hippuric acid synthesis, which appears to be of purely renal origin.

From the point of view of hydrology these findings may explain the results obtained in cases of arterial hypertension by means of treatments by diuretic waters which act energetically on the renal parenchyma. For example, in the course of the Vittel treatment one frequently sees not merely a persistent lowering of the maximum tension—a result which is easily obtained by means of other treatments, but at the same time a simultaneous lowering of the minimum tension, which alone is of any value. On the other hand, I have noted that diuretic waters favour the production of hippuric acid, exciting the renal parenchyma, sometimes to such an extent as to double the output.

SOUTH LONDON HOSPITAL FOR WOMEN, CLAPHAM COMMON.—A garden fête will be held at this hospital on Friday, June 24th, when Princess Helena Victoria will open a sale of work in aid of the funds.

MR. F. B. POWER, Ph.D., was recently presented at Washington, by Mr. Henry S. Wellcome, with a gold medal specially struck to commemorate his services to science during 18½ years as director of the Wellcome Chemical Research Laboratories, London. Dr. Power's researches have been chiefly concerned with the constituents of plants, and more especially those plants used in medicine, and during his directorship some 170 papers were contributed to scientific societies from the Wellcome Laboratories.

THE EVIL EFFECT OF EXCESS OF PROTEIN ON MILK SECRETION.

By GLADYS ANNIE HARTWELL, M.Sc.

(From the Physiological Laboratory, Household and Social Science Department, King's College for Women, Kensington, London.)

OUR experimental knowledge concerning the relation between diet and mammary secretion is not extensive, but it is generally believed that the amount of protein in the mother's diet is an important factor, and great stress is laid on the necessity for giving a larger proportion of protein than normal. It is also recognised by the farmer that a cow in full milk should have a high protein ration. But in a recently published investigation[1] it was found that adding a quantity of caseinogen to the diet of a nursing rat caused the baby rats to die, while the mother remained in apparently good health.

This extraordinary result might have been due either specifically to the caseinogen, or to the fact that excessive protein was being given to the mother rat. To settle this point other proteins were substituted for the caseinogen, and in no case were the litters normal; many, if not all, of the babies died. The few which survived the lactation period were not successfully weaned and lived only a few days after being separated from the mother. None the less the mothers often throve, if appearance and body weight are accepted as criterions.

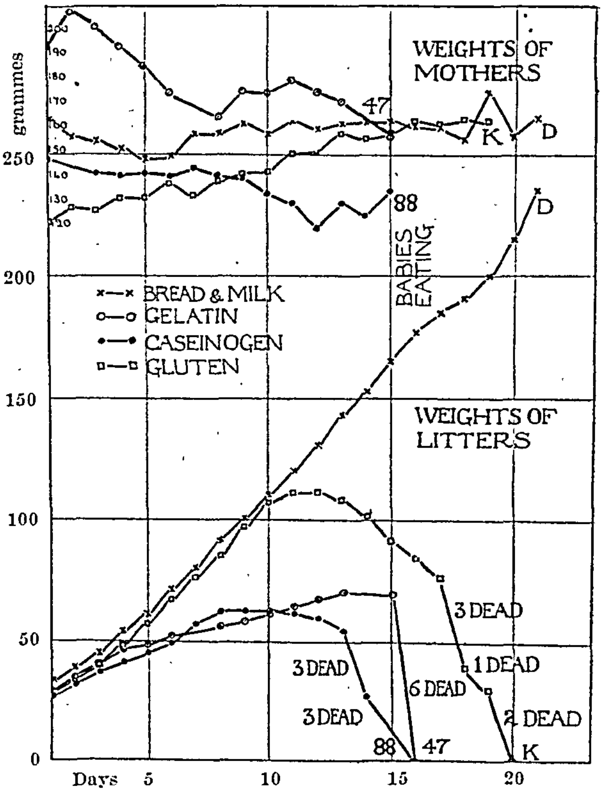
Method of Test Employed.

The litters used were strong and healthy at birth and born of healthy mothers. The mothers were fed on a mixed diet during gestation. The number of the litter was reduced to six to avoid any strain on the mother. (A rat can rear as many as 13 or 14 young.) Mothers and litters were weighed every day, the mothers being allowed to eat as much as they liked. The amounts eaten were weighed. Water was given ad lib. When caseinogen was fed to the mother rat (in the proportion 15·0 g. bread to 5·0 g. caseinogen) the litter did well until about the eleventh or twelfth day, when they ceased to gain any appreciable amount, then lost weight and died. For a few days before the change in the rate of growth appeared, great excitability was noticed. The babies squeaked, kicked and struggled considerably when taken out of their cage. Later they exhibited extensor and contractor spasms, inability to crawl properly, and when still older dashed wildly about, biting their mother and each other. After such fits and just before death extreme exhaustion was evident. The babies were thin and emaciated, and post-mortem examination showed the stomach and intestines to be almost devoid of contents. The intestinal walls were thinner than in a normal animal of the same age. Other proteins used were egg and blood albumins, gelatin, gluten, dried fish, and dried meat-protein.

Effects on Litters.

The effects on the litter were much the same as those already described for caseinogen, the babies nearly always died, and their alimentary canals were practically empty except for small amounts of liquid material and gas in the large intestine. The better the protein, the more drastic the effects—for example, the babies of caseinogen-fed and meat-fed mothers developed worse spasms than those babies whose mothers received gelatin or gluten. Again, the former were very excitable for several days, while the latter exhibited this feature for a short time only, and in some instances it was absent altogether, extreme weakness developing at a much earlier stage. Typical growth curves of the mothers and young are shown in the diagram, and are compared with the maximum growth yet obtained for any litter (example D). Rat D was fed on white bread and milk, a diet physiologically complete in all respects. Whether milk contains any specific stimulus for mammary secretion, or whether it is merely good as containing the necessary foodstuffs, &c., in suitable proportions remains to be proved. It is interesting that litter K (the mother of which was eating an excess of caseinogen) achieved optimal growth until the tenth day, after which it lost weight and finally the young died. Rat 47, which had gelatin, a defective protein, in her diet, lost weight rapidly, and to a far greater extent than if she had been fed on bread only.

The better the protein fed to the mother the more rapid, up to a point, the growth of the young, yet with excess of any protein in the mother's diet, the babies eventually die (or if they survive are by no means healthy or normal). It is suggested that this is due to failure of the milk secretion, preceded by some change in composition which is responsible for the spasms and abnormal condition of the babies. It is unlikely that nursing women ever take a dietary containing nearly as much protein as carbohydrate and practically no fat. But if we may argue from rats to human beings, it is clear that excessive proportions of protein in the mother's diet may lead to metabolic and nervous trouble in the suckling. In view of their possible medical application these experiments are briefly described. A fuller account will be published in the near future.



Curves showing weights of mothers and litters. D, Normal growth, diet of bread and milk. K, Diet of bread and caseinogen. 47, Diet of bread and gelatin. 88, Diet of bread and gluten.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.15).—Clinical Demonstrations, free to medical practitioners, will be held on Tuesdays, Wednesdays, and Fridays, from June 14th to July 22nd. Further particulars will be found in our Medical Diary. An Intensive Course of two weeks duration will be held in September, consisting of morning demonstrations on Clinical Methods and afternoon demonstrations of groups of selected cases. A syllabus will be issued in due course.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY.

A MEETING of this section of the Royal Society of Medicine was held on June 1st, Mr. W. G. SPENCER, the President, in the chair.

Mr. C. A. PANNETT read a paper on

Treatment of Imperfect Descent of Testicle.

He said that all the present methods of treatment were unsatisfactory, and that in the future treatment would probably be the supply of the missing hormone. Meanwhile, the methods orchidopexy and orchidocœlioplasty were at our disposal, though these were by no means ideal. Mr. Pannett then reviewed the methods of orchidopexy. In arrested descent as distinct from abnormal descent (ectopia) all methods of replacing the testicle in scrotum were ineffective. In a case of Bevan's operation, where the testicle was removed a few days later, sections showed a condition of hæmorrhagic infarct in which all the secretory cells of the testicle were degenerated, the internal secretory as well as the spermatogenic cells. This was a very undesirable result, because the imperfectly descended testicle was ordinarily able to maintain the male characteristics. Mr. Pannett proceeded to the discussion of orchidocœlioplasty, with special reference to experimental study on the rabbit. The results observed in this animal were the disappearance of spermatogenic cells and of their derivatives, but the continued activity of other cells, notably those lining tubules, which in the rabbit probably serve an internal secretory function. No vascular lesions and no obstruction of vas deferens were produced as a result of operation. The curious atrophy of the external secretory function was probably due to loss of the assistance in the evacuation of secretion usually supplied by contractions of the cremaster muscle. The testicle was unique in having a very long and tortuous path between the secreting acini and the excreting duct—the vas. The seminal tubules by themselves had not a sufficiently high secretory pressure to overcome the resistance of the 20 feet winding epididymal tube, when unaided by the compression exercised by the cremaster, which squeezed out the contents of testis and epididymis into vas as from a sponge. The practical deductions which Mr. Pannett drew from his experiments and clinical experience were: (1) that when orchidopexy is impossible orchidocœlioplasty should be performed rather than removal or a Bevan operation; (2) that in order to avoid destroying the possible spermatogenic function of an arrested testicle which might descend later on, operation on uncomplicated cases should be postponed until the eighth or the twelfth year; (3) that a bubonocele was no indication for operation; (4) that indications for operation were attacks of strangulation, torsion, or pain (orchitis from muscle trauma). Mr. Pannett concluded by describing the technique of orchidocœlioplasty.

Discussion.

The PRESIDENT expressed his interest in Mr. Pannett's communication, and emphasised the desirability of careful differentiation between the various conditions described by Mr. Pannett. It was especially necessary to distinguish those cases who would be likely to get a delayed descent at puberty. The possibility of the insidious onset of malignant disease must be borne in mind.

Mr. PHILIP TURNER had now abandoned the fixation operation. Many years ago he had started trying to bring the testicle down to the opposite side of the scrotum. The anatomical results of this procedure were satisfactory. As to the distinction made by Mr. Pannett between imperfect descent and ectopia Mr. Turner considered that no sharp line of demarcation could be drawn between these conditions. Mr. Pannett had alluded to the shortness of vessels as a reason against the operation of orchidopexy. In Mr. Turner's experience this trouble was unusual, but shreds of fascia resembling vessels often had to be defined and divided. Mr. Turner did not interfere with vessels. One advantage of bringing the testicle through a septum was that no sutures are needed—if a small hole is made and the testicle drawn through, the septum contracts and exerts a continuous slight force to prevent the testicle from retracting again. In three out of four cases who returned for examination on request a few years after this operation the testicles were well developed and no sign of the operation was detectable. Of 10 cases written to last year seven responded; of these four showed most satisfactory anatomical results; in two the testicle was either smaller than the other or had risen somewhat, and one case was a failure. The age of election for operation was between 6 to 10. It was preferable to operate before the age of 12, because symptoms—usually attacks of pain due to orchitis—seldom arose before that age. He had operated on adults because they desired it. As to a chemical stimulus some had tried thyroid extract, but inasmuch as a patent processus vaginalis was practically always present, Mr. Turner was sceptical as to the possible value of such treatment.

Mr. MCADAM ECCLES put forward a plea for the use of the term "imperfectly migrated" testicle instead of the expression in common use, since developmentally the testis does not descend. He considered that there was little if any alteration in the replaced testicle, since few had spermatogenic functions to start with, but they did have an internal secretion. In Mr. Eccles' experience cases came up more on grounds of definite hernia than for an imperfectly migrated testis, and if the condition was associated with hernia he was convinced that the testicle should not be drawn down to either side of the scrotum in young subjects, because this treatment would destroy its special function. In cases of double internal migration Mr. Pannett's method was the correct one. The glands should be brought right within the peritoneal cavity, the greatest care being taken not to damage the vessels. In an adult Mr. Eccles always endeavoured to bring down the gland, and in these cases Mr. Turner's method seemed to him the most desirable.

Mr. SPENCER MORT said that Mr. Pannett's idea of the squeezing action of the cremaster muscle appealed to him. He asked about the spermatogenic functions of such animals as the elephant, whose testes were in the abdomen, and the cock whose testes were not external. He suggested that by placing in the abdomen both testes of a healthy buck rabbit, and after a suitable interval mating it with a doe, the question as to whether the spermatogenic functions of the rabbit were impaired by this procedure might be determined.

The PRESIDENT agreed with Mr. Turner that longitudinal fibrous bands had often to be severed.

In reply Mr. PANNETT said that if no hernia and no pain were present there was no reason to operate, but after puberty it was not desirable to leave testes in the canal.

Answering Mr. MORT, Mr. PANNETT said that in the cock the testes do not go right up into the abdomen, but are drawn up into the groin, still retaining some contact with the cremaster muscle.

Dr. A. GOODMAN LEVY read a paper on

Cardiac Massage.

He first discussed the general principles underlying the use of cardiac massage. Its sole function was to create an artificial circulation. The term massage was a misnomer, as it was really an effective rhythmical compression of both ventricles that was required. The hand must have access to the right as well as the left ventricle, and the whole heart must be compressed with the movement used on the bulb of a Higginson's syringe. As to surgical technique the method described by Bost and Neve[1] appeared to Dr. Levy to satisfy most nearly the required conditions. In this method the attachments of the diaphragm are cut for two inches, through an abdominal incision. The right hand is inserted into the left pleural cavity and the heart grasped outside the pericardium. During massage the parts are pressed round the right wrist so as to prevent air from entering the pleural cavity. Dr. Levy emphasised the importance of performing artificial respiration, preferably by perflation, but artifical respiration performed by Sylvester's method might be sufficient when there was no opening into the pleural cavity, provided it did not interfere with the proper performance of massage. He attached little importance, to variation of the rate of cardiac compression, as the rate bore no relation to that of the spontaneous beat on recovery. But the occasional interruption of massage was desirable since some observers had found that a spontaneous beat developed more readily after a pause. The limit of the interval between the occurrence of syncope and the commencement of massage depended mainly on the length of time during which the nerve centres could stand deprivation of blood. If the interval were too long severe nervous symptoms, such as tetany, rigidity, incontinence of urine, and cerebral irritation, followed the restoration of the circulation. The generally accepted limit was five minutes. As to posture partial inversion was desirable only in so far as it assisted cerebral circulation and the filling of the heart chambers. Dr. Levy then proceeded to the separate consideration of (1) syncope from overdosage, and (2) primary cardiac syncope. In the former condition artificial respiration alone was usually sufficient to restore the heart beat, but if it had not been applied early enough cardiac massage was called for. In cats Dr. Levy had found the latter uniformly successful. Adrenalin was recommended by Gunn and Martin,[2] but Dr. Levy considered it unnecessary, and in the presence of low blood pressure even dangerous. In this case pituitary extract should be injected. In primary cardiac syncope spontaneous recovery sometimes occurred, but experimental evidence in cats showed that in these animals it occurs only within the first 1¼ minutes. Dr. Levy deduced from experiments that not more than two minutes should be allowed for the chance of spontaneous recovery, and cardiac massage, with intermissions, should be attempted. The duration of massage required varied from one to 48 minutes in a series of 29 cats in which ventricular fibrillation had set in.

Discussion.

Mr. MORT said that he had found by opening the radial artery that forcible pressure in the lower thorax in the course of artificial respiration caused an intermittent flow of blood as great as direct massage of the heart from the abdomen.

The PRESIDENT asked if any case had been known to recover after massage of the heart through a hole in the diaphragm into the left pleural cavity.

Mr. LEVY replied to this question in the affirmative.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

EXHIBITION AND REPORTS OF CLINICAL CASES.

A MEETING of this Section of the Royal Society of Medicine was held on May 27th, Dr. F. S. LANGMEAD, the President, being in the chair.

Dr. J. H. THURSFIELD contributed the notes of a case of

Renal Calculus.

The patient, a girl aged 10 years and 2 months, had been admitted to hospital with a history of recurrent hæmaturia for eight months. There had at times been œdema of the feet and face, and on admission the right ankle was swollen. The urine contained blood, albumin, and blood and epithelial casts. Systolic blood pressure was 124. The heart was not hypertrophied. While the patient was confined to bed the œdema disappeared, but the urine still contained traces of blood. The urine was passed freely in fair quantity and there was no pain. A tentative diagnosis of nephritis was made, but as the bleeding continued and a few pus cells were found in the urine, the latter was examined bacteriologically and found to be sterile. She was then given 15 c.cm. of normal horse serum, and nine days later reacted with a typical macular rash, fever to 99° F., and some reduction of urine, which contained more blood and pus. The diagnosis of nephritis became doubted, especially as a tumour, thought to be a displaced right kidney, could be felt low down on the right side of the abdomen. At this time there was but little hæmaturia and the child was placed on a more liberal diet, and encouraged to get about the ward. The result was an attack resembling uræmia, with scanty urine, hæmaturia, vomiting, headache, and collapse. The hands were in the characteristic tetany position. She recovered and was skiagraphed soon afterwards, the skiagram showing a doubtful calculus on the right side low down. A urea-concentration test indicated that the excretion appeared to be somewhat delayed. Cystoscopy showed that the right ureteric orifice was normal, the left somewhat dilated. A second urea-concentration test demonstrated decided increase of excretion. Tubercle bacilli were now reported in the urine, but four subsequent examinations failed to confirm their presence. By this time the constant presence of the tumour had convinced Dr. Thursfield of the desirability of an operation, and to facilitate the diagnosis further, oxygen was injected into the peritoneal cavity and a skiagram taken. The resulting pictures showed quite clearly a large tumour with the circular shadow, previously noted, within it. Mr. O. Addison operated and extracted a calcium oxalate calculus from the dilated and thickened pelvis of the right kidney. There was no evidence of tuberculosis and no enlarged glands could be felt in the peritoneal cavity. Her recovery was slow, delayed by vomiting and a considerable amount of hæmaturia, but in the course of a fortnight this improved and the child began to put on flesh rapidly.

Dr. J. PORTER PARKINSON showed a case of

Symmetrical Gangrene (? Raynaud's Disease).

The patient, a female child aged 3 years, was the second illegitimate child of an apparently healthy mother aged 25 years. The mother's statement was as follows: The infant had always been healthy, but suffered from chilblains at Christmas; these became swollen and blue in March, and began to discharge a thick yellow matter from the toes of both feet. The sores would dry up and then appear again when the child wore shoes. The toes began gradually to fall off and were found in the dressings. The child was well nourished but small. The Wassermann reaction was negative. The outer three toes of the left foot had disappeared, leaving round sores which had now healed. All the toes of the right foot were missing and the foot was much swollen and very tender, the skin being purple in colour as far as half-way up the leg. This colour had since gone and the swelling was much less. The heart, lungs, abdominal organs, and urine were normal.—Dr. THURSFIELD said that he regarded syphilis as the usual cause of symmetrical gangrene and Raynaud's disease, like hæmoglobinuria, when it occurred in children, as always syphilitic. He asked whether a Wassermann reaction of the mother's blood had been done, as members must all have seen cases of indubitable hereditary syphilis in which the patient's blood was persistently negative.—Dr.

---

[1] THE LANCET, 1918, ii., 552.

[2] Journal of Pharmacology and Experimental Therapeutics, 1915, vii., 31.

PARKINSON replied that no opportunity had been afforded to test the mother's blood. He quite agreed as to the frequency of a syphilitic origin for Raynaud's disease and also hæmoglobinuria, and referred to a family group of cases of the latter disease in which syphilis was shown to be the cause.

Mr. PHILIP TURNER showed a case of

Tumour of the Left External Ear.

It was soft, non-fluctuant, and situated chiefly behind the ear, and recently had been increasing in size, so that it occluded the external auditory meatus, rendering the girl deaf unless she cleared the meatus by traction on the pinna. Recently there had appeared also a swelling over the parotid, and a similar soft tumour of the scalp in the occipital region. One or two hard nodules could be detected imbedded in the tumour. A coarse growth of hair had appeared over the anterior part of the swelling. Mr. Turner regarded the tumour as almost certainly a nævo-lipoma and the harder nodules as foci which had undergone fibrosis. Because of the increase in size, and the blocking of the external auditory meatus, he proposed to attempt to remove it.

The PRESIDENT showed a case of

Cirrhosis of the Liver with Splenomegaly.

For about six months the patient, a girl aged 9 had been ailing, but since the end of April had been worse, complaining of abdominal pain. Blood had been passed with every stool during the first fortnight of more severe illness, and there were also oozing from the gums and epistaxis. Vomiting was occasional. Jaundice of fair severity appeared. On admission early in May, in addition to the jaundice, a few telangiectases were noticeable on the face. The gums continued to ooze slightly. There were some dilated veins in the flanks. In the epigastrium the liver could be felt enlarged, hard, and nodular. The spleen was also enlarged, reaching below the costal margin for about two fingers-breadth. It varied considerably in size and was not hard. After admission slight ascites developed. The cervical and axillary glands were slightly enlarged. Nutrition was good. The jaundice lessened and hæmorrhages diminished after admission. Wassermann reaction negative on two occasions. The urine was normal, containing neither bile pigment nor salts, but was not examined until the jaundice had begun to lessen. A blood examination gave the following results: red blood cells, 4,700,000; Hb, 74 per cent.; colour index, 0·78; white cells, 5500, consisting of polymorphs, 69 per cent.; small lymphocytes, 22 per cent.; large lymphocytes, 5 per cent.; eosinophiles, 2·5 per cent.; large hyalines, 1 per cent.; basophiles, 0·5 per cent. A week later the red blood cells fell to 4.400,000, the hæmoglobin to 66 per cent., and the white cells to 3000. The diagnosis lay between primary cirrhosis, with secondary splenomegaly and Banti's disease. In favour of the latter was the leucopenia. He thought, however, that true Banti's disease—i.e., the combination of splenic enlargement, anæmia, hæmorrhages, and cirrhosis of the liver, with ascites—was extremely rare in young children, much rarer than primary cirrhosis. The occurrence of telangiectasis was a prominent feature of hepatic cirrhosis in children and he favoured that diagnosis.—Dr. THURSFIELD said that many of the cases described as splenic anæmia and Banti's disease in children did not conform to type and present the features which he regarded as essential to the diagnosis. The softness of the spleen in this case was against the diagnosis of Banti's disease and in favour of congestion secondary to primary cirrhosis. The appearance, too, in Banti's disease he considered characteristic, whilst this patient looked too well. Cirrhosis of the liver possibly might be due to an acute infection. An epidemic of fatal cirrhosis had occurred among the deer of Richmond Park, which certainly suggested an infective origin. Gaucher's family splenomegaly had also to be considered in the diagnosis—

The PRESIDENT, in reply, agreed with Dr. Thursfield's remarks concerning splenic anæmia. The softness and variability of the spleen, he thought, was against a diagnosis of Gaucher's disease.

The PRESIDENT also contributed the notes of a case of

? Cerebro-spinal Fever.

The patient, a boy aged 13½, towards the end of February had suffered from pains in the limbs and had developed an eruption of the skin, regarded by the doctor who saw him as erythema nodosum. There were no joint swellings. After an interval of about a week he complained of severe paroxysmal pains in the head, radiating from the temporal region sometimes to the occipital region, sometimes to the forehead, and sometimes to the neck and shoulders. These attacks recurred every few days and were accompanied by fever, gradually rising higher with each attack, and sometimes by vomiting. With the attack there was considerable irritability, the boy being restless and disliking manipulation; there was no head retraction. Between the attacks he was quite at ease and had a good appetite, and physical examination showed no other abnormalities than slight rigidity of the legs, weak knee-jerks, loss of weight, a slight mitral systolic bruit, and slight tenderness over the left kidney, which appeared unduly easily palpable. There had been no urinary changes, but in view of the poverty of physical signs and the palpability of the kidney, it was thought advisable to have the urine examined bacteriologically; it was reported upon as containing *B. lactis aerogenes*. Neither alkalis nor urinary antiseptics caused any improvement, and the boy was admitted to hospital, the attacks becoming more severe and prostrating during the interval of one week. During the first bout of fever after admission the temperature rose to 105° F. Thereafter the attacks of headache and fever occurred every 48 hours for 17 days, the temperature ranging from 92° to 105°, and the chart resembling closely that of benign tertian malaria. Examination during the attacks revealed always restlessness, general hyperæsthesia, flushing, and rigidity of the legs, whilst sometimes there were vomiting, ptosis, and slight squint. The urine remained normal and a second bacteriological examination showed it to be sterile. Radiographic examination of the abdomen was negative. The cerebro-spinal fluid was under slightly increased pressure and contained 6500 white blood cells per c.mm., chiefly polynuclears. Culturally it was sterile on two occasions, nor were organisms seen in a film after centrifugalisation. A blood culture gave negative results, as did also examination for malarial organisms. There was a leucocytosis of 23,000, 90 per cent. of which were polynuclears. Ophthalmoscopic and otoscopic examinations were negative. An agglutination test, using the cerebro-spinal fluid against strain II. of the meningococcus showed no trace of agglutination. Complement-fixation test for tubercle, using the blood serum, was also negative. Quinine failed to modify the fever. After this period the febrile attacks became more occasional. On one occasion he complained of numbness in the left forearm and left leg, and partial anæsthesia was demonstrable in these positions, but gradually disappeared within a few days. A final lumbar puncture was done 21 days after admission, the fluid escaping under considerable pressure. Since then there had been no further rise of temperature and the boy was now convalescent. The knee-jerks were still difficult to obtain and there was nystagmus. In view of the increasing intrathecal pressure, the high polynuclear count in the cerebro-spinal fluid, and the negative findings by other examinations, the case was regarded as probably one of cerebro-spinal fever in spite of the negative bacteriological examination of the cerebro-spinal fluid and almost complete absence of signs between the attacks, which resembled the crises encountered in that disease.—Dr. E. A. COCKAYNE agreed with the diagnosis and referred to a case in which, after the appearance of a rash resembling somewhat erythema nodosum, there were four days of complete intermission of symptoms, followed by definite cerebrospinal fever, which proved fatal.

SOCIÉTÉ DE THÉRAPEUTIQUE DE PARIS.

AT a recent meeting of this Society Dr. ARTAULT DE VEVEY read a paper on

The Treatment of Scabies and Pediculosis by Benzine,

in which he stated that though the parasiticide properties of benzine were well known to naturalists, especially entomologists, they were not generally recognised by the medical profession. He had frequently found that a garden syringe filled with benzine was sufficient to rid a house of ants, beetles, and cockroaches. In the case of scabies, treatment consisted in swabbing the regions affected with benzine, and applying at night an ointment composed of 10 g. of benzine with 50 g. of lanoline, and covering it with wool. The following morning the ointment was washed off with soap and a cure was effected. The body-linen and clothes were disinfected by sprinkling them with benzine, and putting them in a closed chest for a few hours. In pediculosis capitis the scalp was swabbed with benzine, and the head covered with a paper or cloth cap for an hour. Not more than 10–15 c.cm. of benzine need be used. In the case of body-lice the axillæ, groins, and flexures of the limbs should be swabbed, and the clothes and linen treated as in the case of scabies. The only danger, which could easily be avoided, was the inflammability of benzine. The applications were never painful, except over excoriations.

The Treatment of Laryngeal Tuberculosis by Rare Earths.

Dr. G. ROSENTHAL in his paper stated that this treatment must be both local and general. General treatment consisted in giving an intravenous injection three times a week of 4 c.cm. of a solution of didymium sulphate, at first in a 2 per cent., and later in 4 per cent. strength, together with 5–20 c.cm. of concentrated solution of saccharose. Local treatment included (*a*) progressive intratracheal injections of from 2–15 and 20 c.cm. of 1 in 10 gomenol oil, supplemented by 2 cg. of didymium sulphate; (*b*) local applications of the preparations already mentioned, or one of the following solutions: sulphate of didymium 0·02 g., gum arabic q. s. ad 4 c.cm., or novocaine 0·02 g., didymium sulphate 0·02 g., gum arabic q. s. ad 4 c.cm. The only contra-indication to local treatment was weakness of the patient. Great care should be taken in giving intravenous injections in febrile cases.

Dr. R. HUERRE read a paper on

Cedar Wood Oil as a Substitute for Sandalwood Oil,

in which he stated that the chemical composition of cedar wood oil, which contained sesquiterpenes and sesquiterpenic alcohols, showed that it was in no way inferior to sandalwood oil in its action on the mucous membranes.

The Phosphorus and Calcium Balance in Tuberculosis.

Dr. R. LAUTIER in his paper recorded cases showing that, though a nitrogenous deficit or retention was generally accompanied by a deficit or retention of calcium, this was not a universal rule. In like manner the nitrogen balance and phosphorus balance did not always go hand in hand. In order to obtain the best conditions of nutrition or repair, food or drugs containing phosphorus or calcium should not be prescribed haphazard, but should be given in such a way that there should be a slight excess of calcium.

The Treatment of Whooping-Cough by Adrenalin.

Dr. L. DUMONT in his paper stated that this method, which was introduced by an English writer in 1912 or 1913, had been employed by him with constant success since 1913. His dosage was as follows, a 1 in 1000 solution of adrenalin being employed: below 3 years, 2 drops three times daily; from 3 to 7 years, 3 drops every three hours; from 7 to 15 years, 4 drops; above 15 years, 5 drops. The doses must be taken immediately after the paroxysms, so as to prevent the drug being vomited. If no improvement occurred in three days' time, the dose must be increased by one drop daily until a real improvement took place. An attack so treated should not last longer than two to three weeks.

NATIONAL COUNCIL FOR COMBATING VENEREAL DISEASES.—The business meeting of the General Council will be held on Tuesday, June 28th, at 3 P.M., at the Morley Hall Y.W.C.A., George-street, Hanover-square, London, W. The business meeting will be followed by the annual general meeting.

Reviews and Notices of Books.

AN INTRODUCTION TO THE PSYCHOLOGICAL PROBLEMS OF INDUSTRY.

By F. WATTS. London: George Allen and Unwin, Ltd. 1921. Pp. 240. 12*s.* 6*d.*

THERE is to-day a vogue for things psychological, and another for things industrial. The book now before us is concerned with both.

The author starts by proclaiming the need that exists in industry for investigating the human side of work, and for scientific methods "to collect the facts, to arrange them, and to attempt to explain them." When pointing to the underlying influence exerted by the ductless glands upon the emotions he even tempts the reader to expect a physiological explanation of psychology; thus, the effect of emotional excitement upon the adrenal glands, which leads to increase in the rate and force of the heart-beat and promotes effective muscular innervation, is claimed as a factor in industrial fatigue. Fatigue, its onset and elimination, is dealt with at some length, but the subject is treated in too abstract a manner, a not unusual failing with psychologists who write of industry; there is little appeal to facts, of which there are to-day plenty accumulating, small effort to arrange them, but a vast deal of theoretical disquisition and a priori deduction. The section devoted to vocational selection is perhaps the best in the book, although here, too, there is little evidence of real investigation. Attention is well drawn to the need in industry for economical route-ing of human ability, just as there is an economical route-ing of processes; "economy suggests it; humanity demands it." The criticism is particularly applicable to the last half of the book. Here appeal to carefully collected data is thrown to the winds, and theoretical psychology rules supreme. Monotony, for instance, is discussed without establishing by results that any such thing really exists; surely, processes could have been found and instanced, similar in the amount of physical exertion required, in the conditions of labour, in the wages paid, and in other pertinent factors, but differing in the variety of movement called for in the one case and the constant repetition work in the other: observations could then be quoted to establish how important this question of monotony really is, and then would be the time, if at all, to build up a superstructure claimed to be the framework of industrial unrest. We fully allow that by adopting the method pursued an interesting and readable book can be written, and in producing such a book Mr. Watts has succeeded. The pity is that the reader has to disentangle ideas based on fact from those based on some general consensus of opinion. The author has allowed himself rather too many footnotes, which have well been called indications of lazy writing. References to authorities quoted are irregularly dealt with, appearing now in footnotes, now (where they always should appear) in a list at the end of the chapter; here is another indication of slackness in preparation. The index of the book is quite inadequate, and hardly supplements the statement of contents.

We can recommend this book to those who desire to acquaint themselves with the interesting thoughts of an interesting thinker, but we are unable to promise them a solid contribution to the science of the subjects dealt with therein.

ANNALS OF MEDICAL HISTORY.

Vol. III., No. 1. New York: Paul B. Hoeber. 1921. Pp. 96. $2.50.

THE previous volumes were interesting, and the number now before us is no exception to the pattern. Among the papers of chief note is one by Isador H. Coriat, dealing with an ancient Eyptian medical prescription for hysteria to be administered either by fumigation or internally. It consisted of semi-precious stones together with wine and certain plants. It was apparently found efficacious, but still we prefer the simple methods of our more immediate ancestors quoted by Sir D'Arcy Power in his Annual Oration (1920) delivered before the Medical Society of London.[1] Circa 1670, the Rev. John Ward, vicar of Stratford-on-Avon, wrote in his diary concerning the practice of a neighbouring medical man: "Dr. Trig cured a woman yt was troubled with histerical fits this way; he laid her upon ye ground with her face downwards, yn took up her coat and gaue her 3 or 4 good slaps on ye arse, and they cured her."

Another notable paper in the Annals is by Henry Barton Jacobs on Elizabeth Fry, Pastor Fliedner, and Florence Nightingale, all of whom brought about enormous improvements in nursing the sick. Pastor Fliedner was the founder of the Deaconess Hospital, Kaiserwerth. John C. Hemmeter contributes an interesting article upon Leonardo da Vinci as a Scientist, and Harry Friedenwald discusses the giving of medical degrees in the Middle Ages by other than academic authority; references are given to the granting of medical degrees to Jewish physicians by the Pope, in 1402 and also in 1502. We can call two instances to mind not mentioned by Dr. Friedenwald of degrees being granted without academic authority in much later times. In 1657 the poet Cowley, "complying with the men then in power (which was much taken notice of by the royal party), he obtained an order to be created Doctor of Physic, which being done to his mind (whereby he gained the ill will of some of his friends) he went into France again. . . ." This occurred in December, 1657, at Oxford. Again even to day "Lambeth Degrees" in every faculty are or can be granted by the Archbishop of Canterbury, a remaining privilege of His Grace's former position as Papal Legate.

TYPES OF MENTAL DEFECTIVES.

By MARTIN W. BARR, M.D., Chief Physician, Pennsylvania Training School for Feeble-Minded Children; and E. F. MALONEY, A.B., Professor of English, Girard College. London: H. K. Lewis and Co., Ltd. 1920. Pp. 180. 16s.

As the title suggests, this book is a study of a series of cases illustrating the various grades and specialised types of mental deficiency. The authors' aim that the cases should be "sign-posts pointing the way to successful diagnosis" is certainly achieved, for the grading standard is well maintained, the notes on hereditary and environmental conditions are illuminating, and the descriptions of general intelligence, behaviour, and educability of each case give clearly outlined clinical pictures. The absence, however, of any record of examination by the newer psychological methods is a somewhat notable omission in a book on this subject, especially in one which emanates from America. Unfortunately for English readers the grading is not that to which they are accustomed, for Dr. Barr still refuses to use the term "feeble-minded," or even its American equivalent, "moron," for the higher grades, and classifies his cases as "idiots, idio-imbeciles, and imbeciles (low, medium, and high-grade)." His medium and high-grade imbeciles, however, practically correspond to our feeble-minded. This more extensive application of the term "imbecile" makes the use of the term "moral imbecile" less of an anomaly than it is in the English nomenclature, but Dr. Barr's classification is not likely to be adopted here, partly on sentimental grounds and partly because the Mental Deficiency Act has definitely fixed our terminology.

On the subject of moral imbeciles there is still much confusion of thought, from which this book is not quite free. For after speaking of "perversion, or complete absence of the moral sense," as a characteristic of this type, Dr. Barr quotes two cases who could "undoubtedly discriminate between right and wrong," and another who realised that his punishment was deserved. And, as the great majority of the examples cited are, from the descriptions given, obviously deficient in intelligence and therefore certifiable under one or other of the grades already mentioned, one is reminded of Healy's dictum, in speaking of the moral imbeciles, that he had "not found one." Of much interest is the chapter on "idiots savants," those curious types who compensate for their general deficiency by a special talent in one or more directions. One of the cases described has been made familiar to English readers by Dr. Tredgold, who, however, regards the case as one not of primary defect, but of secondary defect due to deafness. Another of Dr. Barr's cases is of extreme interest as showing how the discovery and encouragement of a specific talent caused definite improvement of behaviour and an interest in other work which six years of previous training had failed to produce. From the point of view of operative treatment, the case of a lad who, after castration at 14 years of age, showed greater capacity for training and marked increase of control over his baser instincts, is of some importance. A photograph is given of every case, an unusual and valuable feature, but it has apparently necessitated the reduction of many to a size incompatible with clear definition. It is scarcely possible, for example, to find a Darwinian tubercle in a photograph of head and shoulders the size of a postage-stamp.

The book is well worth careful study by all who have the responsibility of diagnosis of such cases.

TRAITÉ PRATIQUE DES MALADIES DES ENFANTS DU PREMIER AGE.

By GASTON VARIOT, Médecin de l'Hospice des Enfants-Assistés et de l'Hôpital Notre-Dame du Perpétuel-Secours, Chef des Services de l'Institut de Puériculture, President-fondateur du Dispensaire Goutte de Lait de Belleville. Paris: Octave Doin. 1921. With 88 figures. Pp. 1150. Fr.75.

Dr. Variot's new text-book includes a study of the diseases of infants in the first two years of life. The early chapters are devoted to the very important subjects of infant hygiene and infant feeding, on which the author can speak with authority. There is an elaborate consideration of the diseases of the digestive system, with a special chapter on congenital anomalies. Respiratory, cardio-vascular, and nervous systems are treated in turn, and are followed by detailed consideration of congenital syphilis, tuberculosis, specific fevers, rickets, dystrophies, and so forth. The work is essentially personal, and is the fruit of a long career of careful clinical and laboratory study of disease in early childhood. It reads easily and never becomes dull, though it is a most complete treatise on the diseases of infants—in fact, an exposition of the modern teaching of the French school in the matter of infant hygiene and disease.

RATIONAL TREATMENT OF PULMONARY TUBERCULOSIS.

By CHARLES SABOURIN, M.D., Medical Director of the Durtol Sanatorium, France. Authorised English translation from the sixth French edition. Philadelphia: F. A. Davis Company. 1921. Pp. 440. $3.50.

THE author who would write a book devoted solely to the treatment of pulmonary tuberculosis must take his courage in both hands, for he has to run the gauntlet of the hundreds of advocates of various remedies, and he is certain to please few unless he is prepared to give his book encyclopædic dimensions. The present work does not attempt to discuss the latest "advances" in the specific treatment of tuberculosis, and only a page is devoted to vaccine- and sero-therapy. Many other comparatively modern forms of treatment are either wholly ignored or discussed with a brevity that may be taken as the measure of Dr. Sabourin's estimate of their value. He is a sanatorium physician with long and varied clinical experience, and it is evident that he is either ignorant of the enormous amount of new therapeutic work, or that he has found it profitless. His book thus conveys nothing new. But it would be difficult to over-estimate the value of the sound and practical clinical advice he has to give. In almost every page he shows a profound and intimate knowledge of the workings of the tubercle bacillus in the human body and of the many steps which can be and ought to be taken to make the reaction of the host to the parasite victorious. With regard to exercise he is emphatic that it should be aimed mainly at the lower limbs, for the arms are located too near to the lungs to be used freely with impunity by the consumptive. Thus he advocates walking as the most useful form of activity, and he regards sawing wood, even if it be for 15 minutes only, as "highly detrimental." His advice with regard to coughing shows the same sympathetic knowledge of his subject, and he contrasts the unrestrained indulgence in coughing by the untrained patient with the coughless silence of a sanatorium dining-room. The author of the tag—

---

[1] THE LANCET, 1920, i., 1043.

> "It's not the cough that carries you off,
> It's the coffin they carry you off in,"

was more witty than wise, for many a patient coughs himself into his grave who, had he learnt to discipline this reflex, would still be a useful member of the community.

MEDICINE IN VIENNA IN THE PAST.

Das alte medizinische Wien in zeitgenössischen Schilderungen. Von Dr. Med. et Phil. Max Neuburger, O.Ö. Professor für Geschichte der Medizin an der Universität zu Wien. Wien und Leipzig: Moritz Perles. 1921. Mit 9 Abbildungen. Pp. 266. M. 35.

This account of the medical side of Vienna from contemporary records comprises the period from the death of Gerhard van Swieten in 1772 to 1814, the year of the Congress of Vienna, a period when Vienna was the Mecca of the medical pilgrim, and when "Es war nur *ein* Wien." But much has happened since then. G. van Swieten, one of the famous pupils of the illustrious and then all-powerful H. Boerhaave, of Leyden, was called by Maria Theresa, Empress of Austria, to become her physician and to reorganise medical studies in Vienna and in the Austrian Empire generally, which he did with gratifying success, carrying with him the doctrines and methods of the Leyden School. Anton de Haen was brought from the Hague by van Swieten to assist. An account is given of what is called two sensational events in the history of Vienna Medicine—the opening of the General Hospital, with its adjuncts—for maternity cases, also for foundlings, lunatics, and incurables in 1784, and the foundation by Joseph II. of the K.K. Medico-Chirurgical Academy in 1785.

The text is composed of extracts from reports by medical men—German, French, Russian, and English—who visited Vienna and in their travels described what they saw in the hospitals and medical school. The mortality of the "foundlings" seems to have been appalling; one surgeon treated his cases with water dressing and no bandages or plasters even to hold the linen covering in position, another extols plasters and salves; one physician was all for expectant treatment, and others adopted vigorous methods, so that there was plenty of variety in treatment for observation and criticism. We get glimpses of the activities of Störck, Stoll, Plenck, Peter Frank, and others famous in their time; of Mesmer, with his Animal Magnetism, who found fewer fools in Vienna than in Paris; of cases diagnosed into two classes, sthenic and asthenic, and treated accordingly; of the famous oculist, then of European reputation, von Beer; of G. Prochaska, with his wonderful collection of injected anatomical specimens, and some of the original preparations of Lieberkühn; of Gall and his doctrine, and his public lectures in 1786, which, however, were suppressed. We hear of the terrible epidemic of typhus in Vienna after the battle of Austerlitz in 1805, of a visit by K. Ernst von Baer and his impressions. We are reminded, also, of a forgotten incident in the life of Richard Bright by a reference to "Travels from Vienna through Lower Hungary, with some remarks of the State of Vienna during the Congress in the Year 1814." Here we get a picturesque account of De Carro's introduction, advocacy, and practice of Jenner's methods of the cowpox inoculation against small-pox. Bright also notices that of the most celebrated practising physicians scarcely one is an Austrian by birth.

There is much to interest the reader in these studies of the practice and doctrines, as well as the personalities, of a by-gone age in medical history.

CLINICAL STUDY AND TREATMENT OF SICK CHILDREN.

Third edition, revised and enlarged. By John Thomson, M.D. London and Edinburgh: Oliver and Boyd. 1921. Pp. xxxii.–877. 32*s.* 6*d.*

Dr. Thomson brings to his work the outlook of a scientific observer as well as of a clinician, and over and above his acquaintance with disease in children has an inspiring knowledge of the literature of the subject. The only criticism that can be offered is that, doubtless from considerations of space, Dr. Thomson has too often limited himself to a mere recapitulation of symptoms when fuller discussion and expression of his personal views as to their interpretation would have been welcome. Different parts of the book will necessarily appeal to different readers. The opening chapters, dealing with methods of examination of the sick child and with symptoms and signs peculiar to children, will be found especially valuable by the student. Physical constants, and the variations to which growth and development are liable in health and disease are treated comprehensively, and the diet and general hygiene of the infant and adolescent are not neglected.

Certain of the views expressed are not those most generally accepted. For the breast-fed infant, supplementary feeding is advocated in cases where the supply of breast-milk is insufficient. The balance of opinion in England appears to favour alternate feeding as being both more easy to carry out, especially in working-class homes, and on the whole more beneficial both for mother and child. The chapters on rickets and scurvy are brought well up to date; a table of the composition of infant foods is of special value (pp. 162–166), the criticisms of the properties of each foodstuff being pertinent. A chapter is devoted to congenital hypertrophic pyloric stenosis, illustrated by reproductions of photographs which compare favourably with any hitherto published, though this rare condition hardly merits the attention devoted to it. The nutritional diseases of infancy are dealt with at length, and the exposition and discussion of Finkelstein's work on food disorders is particularly illuminating. Dr. Thomson would appear to incline more strongly than do most authorities to Finkelstein's theories, that dietetic errors, particularly improper quantitative relationship between protein, fat, and carbohydrate in the feeds, rather than bacterial infection, are responsible for digestive disorder and its sequela marasmus.

The chapters on child metabolism we have found the most interesting in the book. The causation and treatment of tetany and the nervous manifestations of rickets are treated in a chapter headed "Spasmophilia," while an exhaustive study of cyclic vomiting is placed in the chapter on acetonæmia. The ætiology and treatment of asthma in childhood includes a description of the protein-sensitive tests, and the subject of anaphylaxis receives further attention in Appendix C. As regards the application of organic compounds of arsenic to the treatment of congenital syphilis, Dr. Thomson seems rather more optimistic as to the results of treatment of the later manifestations than are most observers. The relative prevalence of the bovine type of infection in Edinburgh in contrast to the greater frequency of infection with human-type tubercle bacilli in London is discussed. Under existing conditions the boiling of milk is strongly advocated. An apparent contradiction appears on p. 774. After admitting the soundness of the investigations of Ghon and others, who showed that a primary lesion may always be found at the point of invasion of a tissue such as the lung by tubercle bacilli, the lymphatic glands at the hilus being secondarily infected, the author states "in early childhood there is a greater tendency for the lymphatic glands to be severely affected, and it is only when this first line of defence is broken down that the disease is able to reach the lungs." The contention of Ghon was that pulmonary disease reached the lung directly by the air-passages in children as in adults; and that infection of the lungs by continuity of lymphatic paths was unlikely to occur. Dr. Thomson advocates tonsillectomy in cases of tuberculous infection of glands in the neck; he does not devote much attention to the important group of children who show delayed or even complete failure of resolution after broncho-pneumonia, nor to those who suffer from recurrent broncho-pneumonic attacks of catarrh: a warning that these conditions are too frequently diagnosed as juvenile pulmonary tuberculosis might have been helpful to his less experienced readers.

This edition, like its predecessors, is well produced. A comprehensive index and many beautiful illustrations are provided, and the appendices include a Children's Pharmacopœia.

SUGGESTION AND AUTO-SUGGESTION.

A Psychological and Pedagogical Study based upon the Investigations made by the New Nancy School. By CHARLES BAUDOUIN. London: George Allen and Unwin. Ltd. 1920. Pp. 288. 15*s*.

IT is well, at the present time, that the attention of psychotherapeutists should be recalled to the efficacy of suggestion in the treatment of certain morbid states. Before the war a small band of enthusiasts, in this country and other countries, made use of suggestion, with or without hypnosis, in the treatment of functional disorders, and often succeeded in alleviating conditions which had resisted all other methods. Sometimes cures could be recorded, though sometimes claims in this direction had to be turned down. During the war the limitations of suggestion were forcibly impressed upon those medical officers who, often without much previous experience, employed it in the treatment of "shell-shock," and the need felt for some more "rational" therapy, together with the gradual assimilation of some of the doctrines of the psycho-analysts, led in time to a hybrid form of treatment which was neither suggestion nor psycho-analysis. Since the war the tendency would seem to be towards the employment of some form of mental analysis in every case in which psychotherapy is indicated, and the use of suggestion appears to be falling into disrepute. Baudouin's book is therefore opportune in that it serves to remind us that suggestion has still a useful part to play in psychotherapeutics.

The doctrines expounded by him are based on work carried out by Emil Coué at Nancy during the past 10 years. These doctrines are a natural development—indeed, almost an inevitable development—of the views put forward by Liébeault and Bernheim many years ago. Their main feature is the insistence on the importance of auto-suggestion and of the part it plays in all effective suggestion whatsoever. The truth of this has been felt by many who have used suggestion extensively in therapeutic practice; and, indeed, apart from the possibility of some supernormal influence exercised by the hypnotist on his patient, it is obvious, to quote Frederic Myers, that when a subject is told not to feel an aching tooth, "we cannot credit the doctor with doing more than set in motion some *self-suggestive* machinery by which the patient cures his toothache himself." But although the central feature of Coué's doctrines is not new, what *is* new and valuable in Baudouin's exposition is the formulation of the laws and mechanisms through which auto-suggestion works, and the precise description of the most effective ways of bringing them into action.

Perhaps the most important law discovered by Coué is that which Baudouin calls the "Law of Reversed Effort." It is the law exemplified in the attraction which a bunker has for the novice at golf, or a big stone on the road for the budding cyclist. In Coué's words: "When the will and the imagination are at war, the imagination invariably gains the day." It is on the proper appreciation of the relation between the imagination and the will that success in the use of suggestion mainly depends, and a study of Prof. Baudouin's book, in which this topic is fully dealt with, cannot fail to be of great value to the practitioner.

Throughout this work there are numerous references to psycho-analysis, and apparent acceptance of its teachings; but attempts to relate these teachings to those of the new Nancy School are few, and not very successful. Especially is it noteworthy that the writer avoids any discussion of the outstanding contribution of psycho-analysis to the psychology of suggestion—namely, the relation of suggestion to "*transference*." But it is not surprising, and perhaps not regrettable, that in an essentially practical book certain theoretical problems, which are hardly yet ripe for settlement, should be passed over without comment.

ŒDEMA AND NEPHRITIS.

A Critical, Experimental, and Clinical Study of the Physiology and Pathology of Water Absorption in the Living Organism. Third edition. By MARTIN H. FISCHER, M.D. New York: John Wiley and Sons, Inc. 1921. Pp. 922. 55*s*.

THE third and enlarged edition of Dr. Martin Fischer's well-known work contains the same material as the two previous editions, practically unaltered, and also several important additions. The author develops his conception of the hydrophilic colloid in further detail and gives an account of new experiments on the swelling, and solution of gelatin in non-acid media. Another new feature of this edition is a discussion of the nature of the increase and decrease in hydration capacity of the proteins and a more general discussion of the essential nature of water secretion, while some interesting experiments are added on the behaviour of protein colloids in the presence of buffer mixtures. Much of the book has a direct clinical interest, and the relation of chronic interstitial nephritis to chronic parenchymatous nephritis on the one hand, and to arteriosclerosis on the other hand, is discussed from the point of view of acid-intoxication of the respective tissues. The bias of Dr. Fischer's views is well illustrated by his statement that "any means which leads to an increased production or accumulation of acid in the kidney is a means of "producing nephritis"; and again, in the classification of the several forms of nephritis, in his statement that "there is but one form of nephritis—parenchymatous nephritis." No succinct definition of nephritis is given; the author says that he uses the word in its ordinary clinical sense and yet he seems to regard the albuminuria that follows hard physical exertion as evidence of nephritis. Another word that requires more exact definition is "acid-intoxication," for the ambiguous sense in which acid-intoxication is used has led to the assumption that it means hydrogen-ion concentration. The book would be improved for the general reader if a chapter were added dealing with this fundamental question and defining the differences between acid-intoxication, hydrogen-ion concentration and titration acidity. The subject would be further simplified if it were possible to measure the degrees of acid-intoxication in the body tissues. This is, however, an enormously difficult matter, since alkalies and other substances in addition to acids may increase the hydration capacity of colloids.

If the reader is content to leave such matters as these wrapped in mystery he will yet be interested in the clinical aspect of the author's views; he may, in fact, be prepared to judge them on the success attained in the treatment of œdema and nephritis on the lines that Dr. Fischer lays down.

TUBERCULOUS SALPINGITIS.

A Clinical Study of 200 Cases. By J. P. GREENBERG. The Johns Hopkins Hospital Reports. Vol. XXI., Fasc. 2. Baltimore: The Johns Hopkins Press. 1921.

THIS monograph is based upon an analysis of all the cases of tuberculous salpingitis which occurred in the gynæcological service of the Johns Hopkins Hospital during the years 1890–1919 inclusive. The author found that this condition was present in nearly 1 per cent. of all women admitted to the gynæcological service, and that of every 13 abnormal tubes removed by operation one was tuberculous. It occurs most commonly in young sterile women, of whom one quarter had pulmonary tuberculosis. The chief symptoms are abdominal pain and leucorrhœa. In two-thirds of the patients there was some elevation of temperature, and one-half had lost weight. In very few of the cases was a correct diagnosis made before operation, which was performed in rather more than half the cases. It was found that abdominal fistulæ were much commoner among the cases which were drained. The tubes were involved most frequently of the pelvic organs, and next in order of frequency were the uterus, ovaries, cervix, and vagina. In 99 per cent. both tubes were involved. The operative mortality was 7·6 per cent. and of 90 patients traced 78 were found to be living from two months to 30 years after the operation. Nearly all those alive were in good health.

THE SPUTUM.

By Prof. Dr. HEINRICH VON HOESSLIN. Berlin: Julius Springer. 1921. Pp. 398+x. M.148.

WE confess to having opened this volume with a certain amount of anxiety. Four hundred pages on the subject of sputum alone seemed to promise redundancy, but the work has afforded us considerable pleasure. It was apparently prepared for publication in the summer of 1914 and was held over by the publishers owing to the outbreak of hostilities. As the author himself points out in his preface, it would be difficult to produce such a work now under the changed conditions of the publishing world.

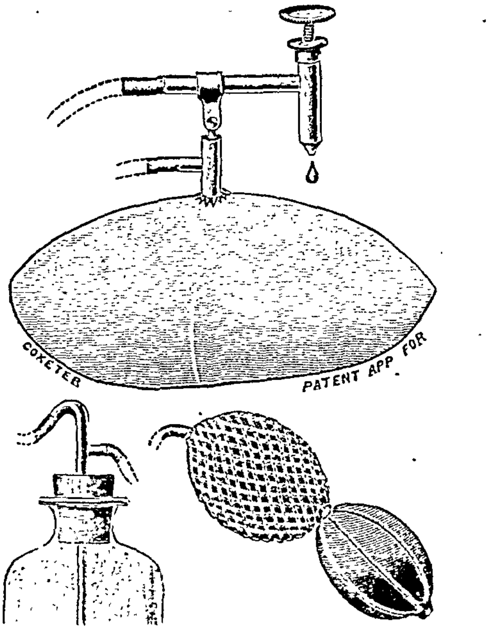
Prof. von Hoesslin has filled a gap in clinical pathology. The consideration of sputum examination is generally relegated to a short chapter, even in works on clinical pathology; but neither pathologist nor clinician can complain here. The book is one to which it is almost impossible to do justice in a review, because it is packed with facts from first to last page, covering the ground from the naked-eye examination of sputum to the bacteriological cultures and differential diagnosis. The cytology, macroscopical and microscopical appearances, the technique of the examination of pigment, the qualities of elastic tissue and crystals, and the chemistry of sputum occupy together rather more than half the book. The second portion deals with the bacteriological aspect of the subject. The accounts given of some of the organisms is not quite as detailed as it might be (e.g., streptococcus, pneumococcus), and the protozoa, notably the spirochætes, do not receive much attention—so hard is it, even in the largest text-book, to be quite comprehensive. The higher bacteria, such as the mucor group, which are liable to give a good deal of worry in the examination of sputum owing to difficulties of classification, culture, and pathogenicity, are not dealt with quite adequately from the point of view of a practical laboratory worker. Perhaps a fuller consideration of non-pathogenic mouth organisms would have cleared up these points.

Diagrams, tables for differential diagnosis, coloured plates—some of them typical, others unconvincing, but practically all well executed—are numerous. It is with relief that we note the omission of the old engravings of Curschmann's spirals which disfigure some text-books, and find instead the inclusion of a series of really beautiful drawings of this somewhat rare appearance in sputum. But perhaps the best indication of the thorough way in which Prof. von Hoesslin has done his work is to be found in the forty closely printed pages of references at the end of the book. We trust that it will not be long before Prof. von Hoesslin has the opportunity of bringing out a second edition of this work in which he will be able to add all the new work of the war years, including the diagnosis by "types" of the pneumococcus and meningococcus, and other recent advances on the bacteriological side. This volume is chiefly valuable as a good reference book on a subject which has hitherto been scattered about the literature of medicine and pathology, and the fuller it can be made the better for the research worker to whom it will largely appeal.

New Inventions.

AN AUTOMATIC ANÆSTHETIC INHALER.

THE inhaler here illustrated consists of a mask to which is attached a small dropper, which can be fixed in any position. The drops are regulated to any speed by rotating the milled head of the valve. The anæsthetic in the bottle is subjected to air pressure by means of rubber bellows, and is forced through the tube from the bottle to the dropper. When the bellows have been pumped up the liquid continues to flow through the tube at a constant drip for a considerable time without attention, the length of time depending upon the size of the bellows used. The small tube at the side permits oxygen to be given if desired. A rubber band can be used to secure the mask to the patient's face. This mask was designed for use with ethaneseal, but can, of course, be utilised for any liquid anæsthetic.



C. LANGTON HEWER, M.B., B.S. Lond.
Marylebone, N.W.

THE LANCET.

LONDON: SATURDAY, JUNE 11, 1921.

The Revival of Morbid Anatomy.

NINE years ago the late Sir JAMES GOODHART delivered the Harveian Oration, choosing as his text the Passing of Morbid Anatomy. Whereas, he said, we used to display disease in the gross, the results of disease that is, we are now able to recognise finer changes and more minute evidences of bioplasmic unrest that are behind these results, and they are the goal that we make for now. He had just met the first biochemist. "And pathology still is shifting!" added the orator. That it is possible to question the value of morbid anatomy to medicine might seem absurd to one who had not followed closely the trend of medical thought in the crowded years since GOODHART's masterly address; but there is no doubt that the pendulum has been swinging somewhat wildly, not only backwards and forwards, but also from side to side, with the result that progress has been erratic. Sir G. SIMS WOODHEAD in our correspondence columns raises points of considerable interest, and particularly worthy of attention is his plea for a more general performance of post-mortem examinations. The last two or three decades have witnessed dramatic discoveries in parasitology, immunity, biochemistry, and physics, and the more humdrum field of morbid anatomy has been to some extent neglected. As is only natural, the recruits have flocked to those branches of medical science which seemed to offer the most brilliant future, for rich harvests are more easily gained from virgin soil than from land which has long been cultivated. But it is becoming clear that even in these fields the obvious discoveries have now been made; future progress can only result from intensive effort, and day by day the boundaries of the expert's knowledge in his own particular science are becoming more and more restricted; the bacteriologist is becoming divorced from the serologist, and in biochemistry a man may lead a full and useful life as a pure devotee of the lipoids. Similarly, on the clinical side, whereas the old-time physician studied all the ills of the body, the modern specialist is often content with a single system as his province, or even a single microbe, for the *Treponema pallidum* and the tubercle bacillus have both their cults, while the activities of a surgeon are frequently limited to districts marked out in the human body by imaginary horizontal lines. This modern system has undoubted advantages, but it suffers from a serious drawback; it is prone to cause atrophy of that most important sense, the sense of proportion. The physician exalts his own particular system above all other organs of the body; the student of vitamins is blind to everything but his mysterious protégés; and the bacteriologist forgets that microbes are, medically speaking, of no importance at all except for the effects they produce on human tissues.

It is necessary, from time to time, for the enthusiast to be brought down to earth that his observations and theories may be compared with cold fact and the test by which he must be judged is morbid anatomy. Physical signs are worthless unless they actually correspond with pathological lesions, and microbes or positive serum reactions must be correlated with definite lesions before they can claim to possess more than an academic interest. This unfortunately necessitates a high degree of coördination between the various workers, a difficult matter, but one which must be faced. The older physicians, such as BRIGHT and ADDISON, needed no pathologist to help them, for they were their own morbid anatomists. They followed their cases to the post-mortem room, and themselves sought there for an explanation of the signs and symptoms they had detected during the patient's life. Liaison officers were unnecessary in those days, but now they are essential. With the progress of morbid histology, pathology has become a vastly wider subject. The detection of gross lesions is no longer sufficient, their elucidation by histological studies is equally necessary, and the physician is therefore compelled to rely upon the expert pathologist. On the other hand, no morbid histologist desires or even claims to be in a position to do his own bacteriology; though, in its early days bacteriology was practised by the general pathologist, the science has now become too unwieldy for this, and demands its own practitioners. But while it is of the utmost importance that all clinical observations, as well as the investigations of the experts in the newer sciences, should be controlled by morbid anatomy, there is another side of the question. Morbid anatomy is a living science, and every day fresh discoveries are being made in the post-mortem room or the histological laboratory. These can only be of value, however, if we understand what they mean, and a proper understanding can only be arrived at by the help of the clinician and the workers in other fields. Just as in the post-mortem room the true meaning of the signs and symptoms recorded in the clinical notes of the case is made clear, so in the records of other workers may the pathologist hope to find the key to his own investigations.

No amount of coördination, however, between himself and his colleague can help the pathologist if there is lacking the coöperation of the lay public. It is true that he may learn much from the study of tissues removed by operation, and it may be pointed out in passing that the so-called science of the pathology of the living comes finally to the study of tissues which have been killed, but the greater part of his work is concerned with the dead. Only in the post-mortem room can he study the late results of disease, and the earlier, even the earliest, manifestations of morbid processes. And here the force of public opinion is directly opposed to his labours. Time after time the work of the clinician is rendered worthless so far as the advancement of knowledge is concerned by the refusal of permission to make a post-mortem examination. And this state of affairs is likely to continue till education and the growth of a more logical mode of thought shall sweep away the prejudice and false sentiment of the layman. If we were asked in what way a thousand persons could best serve the interests of medical research, we would say by leaving orders that post-mortem examinations should be performed on themselves, and by pledging themselves not to refuse permission for similar investigations on their relatives. Such a series of autopsies, if performed by trained observers in the light of such clinical records as Sir SIMS WOODHEAD suggests, might be of incalculable value to medical science and of real benefit to mankind.

Insanity in Law and Medicine.

THE coöperation of medical practitioners and lawyers is necessary whenever questions have to be settled at law relating to insane persons, whether such questions refer to the detention and safe custody of these unfortunate subjects, their civil rights, or their civil or criminal responsibility for their acts. Consequently a paper read recently by Dr. W. G. H. COOK, a barrister and Doctor of Laws, before the Medico-Legal Society, upon the Liability of the Insane in Respect of Civil Wrongs, dealt with a subject very appropriate for such joint consideration. The criminal responsibility of the insane person, and of the person whose defence to a criminal charge is that he was insane when he committed the act, is frequently considered by the courts, and, whether members of the medical profession may approve or not of the test of insanity adopted by the law for such trials, that test is well established and well known. It is not so generally known, and it may have come as a surprise to some of Dr. COOK'S audience, that the degree of liability imposed by the common law upon the mentally deranged person when sued in civil courts differs from that which obtains in criminal trials, and indeed is not defined with any certainty. It has been dealt with to some extent in text-books, and has been the subject of obiter dicta by judges, but no leading case in which the degree of insanity which will excuse a man from the civil consequences of a tortious act appears to have occupied the attention of the Courts of Appeal, so as to supply a precedent of recognised weight.

The general effect produced by Dr. COOK'S survey of the law in the light of such precedents as exist, was that whereas the intention to do wrong is the essential feature of the act which brings punishment upon the wrong-doer, the point of view in a civil action is different. The law is not there enforced by the State in order that crime may be penalised or prevented for the future. It is set in motion by a person who has suffered damage in order that he may obtain compensation for loss or injury inflicted upon him. The consequences of a certain act have to fall upon someone, and the tendency of the law from the earliest times has been to compensate, and to let the insane person bear the burden of his own act, rather than it should be endured by his innocent neighbour. Dr. COOK was of opinion that the general tendency of recent cases bearing on the subject was to excuse the person incapable of an intent to injure, and that this was consistent with the general policy of the law. In opening the interesting discussion which followed, the chairman, Mr. Justice ATKIN, pointed out that the latter contention was open to question. He gave as an example of a tort, in which intent to injure need not be proved even in a sane person, the case of a libel, for the publication of which an action would lie even if the person publishing it was not aware that he was defaming the plaintiff. The speakers who followed, and who included Sir WILLIAM COLLINS and Sir ROBERT ARMSTRONG-JONES, added valuable criticisms, and appeared to be in agreement as to the difficulty of defining insanity with Lord BLACKBURN, who was quoted by Dr. COOK as having said that he had never been satisfied with any definition, and had endeavoured in vain to make one, adding, "I verily believe that it is not in human power to do it." It may be suggested that such definition is for Lord BLACKBURN'S successors on the bench, and not for the medical profession, to consider with a view to the uses to which it is to be put. It will then be for medical men to say how far the individual case comes within that definition or lies outside it. The whole question of the law in relation to insanity is, as has been suggested, eminently one for the Medico-Legal Society to ventilate and discuss.

◆

The Relations of Medicine to Industry.

A MEETING of medical men, working in connexion with industrial establishments, was held on June 2nd at the offices of the Industrial Welfare Society, Westminster, and may mark the beginning of a valuable movement. The meeting was presided over by H.R.H. the DUKE OF YORK, the President of the Society, and was well attended, while our brief report of the two discussions (p. 1257) will show alike the pioneer work which has been done, and the difficulties which stand in the way of quick and smooth progress. It happened that on the same day a series of conferences was commenced at the Guildhall under arrangements made by the Royal Institute of Public Health, when, at one of the Sessions, industrial medicine was the subject of debate. This series of conferences was also opened by the DUKE OF YORK, who in his speech declaring the proceedings open, used the following words: "Industry has too long been carried on without thought of its effect on the worker." The DUKE OF YORK recognised the real reason for holding the meeting.

The conference at Westminster was of a strictly practical nature; it was concerned, firstly, with what could be done to maintain and improve the health of the workers, the second question being what steps ought to be taken to make the resulting advantages of healthy labour quite clear to the minds of the employers. This definite movement on the part of practitioners connected with industrial establishments has been made opportunely. From our report of the comprehensive discussion at the Guildhall it will be seen that each of the medical services of the country still awaits arrangement and coördination, so that at the present moment there is room for new activities to establish themselves and to plan their programmes without interference from old-established customs or interests. The work which has already been done in the factories, for example, in the avoiding of tragedies by timely examination of workmen, and in the prevention of sepsis by prompt attention to injuries, are examples of what may be expected to become commonplace routine; the establishment of dental clinics at many works, the provision of trusses, the shortening of disablement period after accidents by electrotherapy and massage, clinics at the works, the provision of half-time, or light work for convalescents, the removal of men from dangerous work at an age when slight accidents might make them permanent cripples, are examples of care for the individual worker which are already in evidence. But much remains to be done to make unhealthy processes healthy, and to remove the causes of long-standing ills. Industrial phthisis presents huge difficulties. The presence of the doctor in the works, on the Whitley Councils, and on the works committees, will help towards dealing with this difficult situation. But we must go cautiously to begin with. The average medical practitioner has had little opportunity as yet of studying these problems practically or at close quarters with employer and employed, despite the real desire of all to aid and abet sound therapeutics.

Any attempt to upset the management of industrial concerns by ill-considered advice founded on book knowledge would inevitably bring the whole medical movement into discredit. Experience at the works will bring invaluable lessons, but a course of preliminary training would make that experience doubly valuable. There was general agreement at the conference that the general practitioners would have the chief part to play in the improvement of industrial health, perhaps through a rota of works doctors, in which case the works clinic and ambulance room would resemble a "centre" under the Dawson scheme. Whatever the exact method may be that future consideration decides upon, the works doctors must be in close touch with the general practitioner and with the certifying factory surgeons.

We must not make industrial medicine into another "close" specialism, and it is obvious that if the general practitioner is to acquire a preventive outlook, he must have the opportunity of studying the effect on his patient of both home and occupational conditions. We may have concentrated too closely on home conditions. How often have we heard the declaration at health conferences that "consumption is a house disease" by speakers who ignored the well-known effects of certain occupations, and the evidence of the doubled death-rate from tuberculosis of the lungs among males when compared with females. The Industrial Welfare Society (to quote its journal) voices the longing for a revival of practical goodwill between employer and employed. One of the conference speakers said: "This movement must be based on medicine." We feel sure that the medical profession will rise to the occasion and worthily play its part in what the *Daily Telegraph* last Saturday described as "that most promising of modern developments in industry, the prevention of ill-health and the promotion of efficiency in general by medical care in the factory and the workshop." Once inaugurated on safe and sound lines, industrial medicine is likely to go ahead faster than some may think.

FATE OF A BRIGHTON HOSPITAL SCHEME.—A Brighton correspondent writes:—"The only maternity hospital in Sussex is the Brighton and Hove Hospital for Women in West-street, with two small branches—one in Brighton and one in Hove. The institution is in the ninety-first year. Before the war the need of larger premises was so pressing that, an excellent opportunity arising, an old school building was actually secured and would have soon been transformed into a hospital but for the outbreak of hostilities. Within a day or two of the actual taking over by the hospital of their new building the Government commandeered it, and it became the Second Eastern General Hospital, the hospital returning to its old premises. There is no need to enlarge on the changes the war has brought about, but since the return to the new premises negotiations have been going on with the Health Committees of the Brighton and Hove Town Councils and the East Sussex and West Sussex County Councils with the object of coördinating the work of the hospital with the needs of the area it serves, and these have been fatal to the hospital. The final decision was made on May 26th by the Brighton Town Council, which body agreed as follows:—(1) In view of the circular of the Ministry of Health urging that no fresh capital expenditure should be undertaken which can be postponed without material risk to public health; (2) as three of the local authorities concerned have already withdrawn from the scheme; and (3) owing to the high cost involved in the carrying out of the scheme the Town Council cannot proceed further with the scheme. It is a pity such a hospital—dealing with over one thousand maternity cases every year—to say nothing of visits to out-patients—cannot secure the additional accommodation which it so much needs. The raising of a healthy population begins at the cradle."

Annotations.

"Ne quid nimis."

THE BIRTHDAY HONOURS.

THE list of honours issued on the occasion of the official celebration of the King's Birthday contains the names of several medical men who have rendered eminent service both to the profession to which they belong and to the State. Among the new knights are Mr. Arthur Keith, F.R.S., Hunterian Professor and Conservator of the Museum of the Royal College of Surgeons of England; Dr. Thomas Lewis, F.R.S., honorary consulting physician to the Ministry of Pensions; and Dr. Sydney Russell Wells, Vice-Chancellor of the University of London and its Representative on the General Medical Council. In the Irish list is the name of Dr. F. C. Dwyer, ex-President of the Royal College of Surgeons in Ireland, Chairman of the House of Industry Hospitals, and Inspector of Anatomy in Ireland, and in the Colonial Office List Brigadier-General D. J. McGavin, Director-General of Medical Services in New Zealand; both these distinguished medical men have received the honour of Knighthood. In the Order of the Bath Surgeon Rear-Admiral P. W. Bassett-Smith, C.B., is promoted to Knight of the Order, while Colonel C. E. Pollock, D.S.O., Assistant Director of Medical Services, Eastern Command, receives a Companionship of the Military Division. Major-General W. M. Edwards, Director-General, I.M.S., and Colonel W. H. Willcox, late medical adviser to the civil administration in Mesopotamia, receive Knight Commanderships of the Order of the Indian Empire; and Lieut.-Colonel B. H. Deare, I.M.S., Principal of the Medical College, Calcutta, and Dr. Mohendra Nath Banerjee, Principal of the Carmichael Medical College, Belgatchia, Companionships. Major W. D. Neal, Indian Medical Department, becomes a Companion of the Imperial Service Order, and Dr. Ernest Muir, of the School of Tropical Medicine, Calcutta, research worker and missionary, the Kaisar-i-Hind Medal of the First Class. Sir Ernest Hodder-Williams, chairman of Wakley & Son, Ltd., proprietors of THE LANCET, has received the Commandership of the Royal Victorian Order. We congratulate these recipients of well-earned honours.

NEW SOUTH WALES AND INFLUENZA.

THE report for the year 1919 of the Director-General of Public Health for New South Wales is a monument to the thoroughness with which the work of the department is carried out, and in its 273 large pages contains full details of everything connected with public health work, from the usual mortality returns to the value of the 121 pairs of beaverskin trousers made at the State Asylum for Aged and Infirm Men, Parramatta. Section five, which runs to 100 pages or more, consists of the report on the influenza epidemic of 1919 and is an admirable account of that invasion, considered under the following headings: Epidemiology, Administrative measures, Mortality statistics, and lastly the Pathological, bacteriological and ætiological investigations into the epidemic in Sydney, contributed by Dr. J. B. Cleland, principal microbiologist to the department. It is interesting to read that the quarantine cordon was successful in preventing the arrival of the second and virulent wave until January, 1919, whereas infected ships reached the ports in October, 1918. The actual case-mortality was not so high as it was in England. Careful investigations have shown that in the metropolitan area 290,000 persons, or 36·6 per cent. of the whole population, were attacked with a mortality of 3902, or 1·3 per cent. Among pregnant women not previously inoculated the mortality-rate was found to be 30·6 per cent., while in those who had been inoculated previously it was found to be 9·5 per cent. Both figures confirm the very grave risk the disease brings to expectant mothers.

The prophylactic measures taken were remarkable and complete. Proclamations were issued closing all libraries, schools, churches, theatres, picture-palaces, and all other places of indoor entertainment. The wearing of masks in trains, trams, public places, and shops was made compulsory. Public meetings for any purpose either indoor or in the open air were prohibited, racecourses were closed, and church services, at first prohibited, were only permitted in the open air under certain restrictions and regulations for the quarantining of influenza contacts. As regards protective inoculation, Australia had an unique opportunity to exploit the value of this measure. The time which elapsed between the arrival of the first influenza infected ships in October, 1918, and the invasion of New South Wales in January, 1919, was utilised by the department to manufacture large quantities of mixed vaccine having the following composition:—

Pneumococcus	1000 millions.
Influenza bacillus	100 ,,
Streptococcus	100 ,,
Staphylococcus aureus	250 ,,
M. catarrhalis group	250 ,,

A conservative estimate of the total number of inoculations performed in New South Wales was 819,083, which brings the number of people so treated to 404,803. In Sydney between 35 and 40 per cent. of the whole population were inoculated. Among the inoculated the mortality was 10·7 per cent.; among those not inoculated it was 16·5 per cent. Further, it is shown that the mortality fell regularly according to the number of inoculations. Among those inoculated once it was 11·1 per cent., among those twice inoculated 10·1 per cent., and it was 8·2 per cent. among those inoculated three times. The effect of inoculation in preventing an attack is known to be slight, if any, but figures are here produced which show that it has no tendency to increase the susceptibility of the person inoculated, or in other words, the question of the negative phase may be disregarded.

Dr. Cleland summarises his personal deductions from the immense amount of information he had at his disposal and amongst his conclusions from the pneumonic cases he states that:—

1. The primary ætiological agent of influenza is unknown but is probably a virus of the filter-passing group.
2. The primary lung lesions are probably directly due to this virus.
3. Both lungs are usually more or less involved, the upper lobes in most cases, the lower lobes less often.
5. In fatal pulmonary cases a bacterial growth is usually obtained comprising one, two, three, or more groups of bacteria, of which pneumococcal organisms are the most prevalent, while the influenza bacillus, streptococci, and *Staphylococcus aureus* occur in about one-third of the cases.
6. These bacteria are believed to be secondary invaders flourishing in the exudate and hæmorrhagic areas resulting from the primary virus.
8. Vaccines seem to have led to a quite distinct though not very great diminution in the mortality.
9. Inoculations of animals with infective material have proved of no value except to show that the rhesus monkey is almost completely refractive to the disease.

The macroscopic features presented by the diseased lungs were protean in character, so much so that it is difficult to describe in general terms the appearances that may be expected in any one case. A series of very beautiful coloured plates illustrates the various lesions found in the lungs, and the coloration produced by them; the appearances in the Australian epidemic being precisely similar to those recorded in England, France, America, and other parts of the world during this widespread epidemic. When discussing the use of vaccines Dr. Cleland mentions the remarkable feature which has been observed in this country also, not only in connexion with influenza vaccine, but after the use of T.A.B. vaccines in the army during the days of the war—namely, that many persons suffering from forms of chronic rheumatism or other complaints of a similar nature derived unmistakable benefit from the injections. It was found that a number of persons made a practice of attending the inoculation depôts weekly in order to maintain the benefit they derived for these chronic affections. Dr. Cleland concurs with the views of observers over here, that the beneficial substances are the foreign proteids introduced into the systemic circulation. Emphasis is laid on the value of masking both as a means of preventing the exit of the virus from those infected and of preserving the non-infected from inhaling infection.

The report forms a very complete record of an epidemic which it was possible to observe from before its commencement to its, fortunately, not long-delayed termination. As an account of the measures both preventive and curative which can and should be taken by an intelligent administration it is of the highest value and the work should be retained for reference in all medical libraries.

SELF-DISINFECTION: THE GOVERNMENT'S ATTITUDE.

THE Ministry of Health has sent a circular dealing with the prevention and treatment of venereal diseases to the authorities of counties and county boroughs in England and Wales. We give the substance of this circular on p.1256. After careful consideration of the evidence the Government, it is stated, find that there is general agreement that the best way to avoid risk of venereal disease is to abstain from promiscuous sexual intercourse, disinfection applied immediately after exposure to risk of infection being effective only to the extent to which it can be thoroughly applied in the particular case. They find that medical opinion is divided as to the practicability and likelihood of the success of self-disinfection by the civil population, whereas on the moral and social side weighty objections have been advanced against it. In the circumstances the Government have decided that, whatever the individual or groups of individuals may practise or recommend, they cannot make a system of self-disinfection for the civil community part of their official policy. It is hoped that this clear statement on behalf of the Government may form a useful basis for united coöperation of persons and societies concerned in the campaign against venereal diseases.

EXHIBITION OF X RAY PHOTOGRAPHS.

INTERESTING X ray photographs are being shown at the house of the Royal Photographic Society, 35, Russell-square, London, W.C. The exhibition is under the auspices of the Rontgen Society, and contains more than 250 prints, some of which arrived by special aeroplane from Paris too late to be included in the official catalogue, though short descriptive notes are attached where available. Specimens of the work of the late Dr. C. Infroit, of the Hospice de la Salpêtrière, Paris, are on view. Drs. Vignal, Haret, and Contremontez have sent remarkable examples of their radiographic work, and specimens of metal radiography have been contributed by the firm of Giaffe-Gallot and Pilon. Among the notable work contributed by radiographers in this country is a fine series of prints illustrating various abnormalities of the vermiform appendix, by Dr. C. Thurstan Holland. The Cancer Hospital is represented by some good prints recording the progress of opaque meals. Prints of paintings are shown by Dr. A. Chéron and the Sunic Research Laboratory, and illustrate the application of radiography in the detection of fraud. Some photographs taken by Mr. A. Campbell Swinton in 1896 are of historic interest. Dr. R. W. A. Salmond shows some good work, and the comparative results obtained with the new Impex plates and the ordinary X-ray plates, by Dr. G. H. Rodman, the president of the Royal Photographic Society, are of special interest. A series of plates taken with a portable apparatus in France, by Miss Phyllis Berry and Miss Collum, late of the Scottish Women's Hospital, illustrates some of the war-time applications of the X ray. The exhibition generally marks a distinct advance, and the opportunity of direct comparison of the work of radiographers in this country with that of workers abroad is of considerable value in demonstrating different methods of procedure. The series of sets of four prints produced by lay workers employed either in the radiographic departments of hospitals or acting as assistants to qualified radiographers, are specially helpful in this respect, entries for prizes offered by Dr. R. Knox are of a high standard. The first prize has been awarded to Mr. Suggars, of the London Hospital, and the second to Mr. A. O. Forder, of King's College Hospital. The exhibition will remain open daily throughout June (Sundays excepted) from 11 A.M. to 5 P.M., and admission is free.

EXCESSIVE PROTEIN IN DIETS.

WE drew attention in THE LANCET of April 16th to the important observations of T. B. Osborne and L. B. Mendel, of Yale University, on growth with diets poor in true fats, and growth without preformed carbohydrate in the diet. The same observers[1] discuss the question of growth with diets containing more than 90 per cent. of protein. Although it has been demonstrated that a carnivorous animal can be kept alive and maintained in activity for considerable periods on an exclusive diet of meat, it is not known whether growth as well as maintenance can proceed on a regimen entirely free from both fats and carbohydrates. Hammarsten has stated that omnivora and herbivora cannot survive on such a ration. The authors' successful experiments in growing rats on food extremely poor in fats and in carbohydrates respectively encouraged them to test diets containing only minimal quantities of *both.* The mixtures included protein 95 per cent., inorganic salts 5 per cent., with a supply of vitamins A and B in the form of tablets of alfalfa (0·4 g.), and dried brewery yeast (0·2 g.) daily. On such diets, when casein furnished the protein, animals have already grown to three times their weight at the beginning of the trial. The vitamin-bearing substances were the only noteworthy sources of either fat or carbohydrate, and supplied 4–8 per cent. of the food eaten. If future experiments prove as successful as those described by these authors, then various problems of nutrition and physiological function can be approached from new experimental standpoints. The earlier experiments by Hammarsten, few in number in relation to this problem, were conducted on a less satisfactory plan, the food mixtures being inadequate in respect to one or more essential factors. It is to be noted that in Osborne and Mendel's experiments the growth of the rats was observed only until their weight was trebled. It has still to be determined whether rats will attain adult size and normal functions on diets furnishing proteins as the almost exclusive source of energy and tissue substance. The communication in our present issue from Miss G. A. Hartwell would seem in the first place to indicate that there may be exaggeration even in the diet of a lactating mother. We know little of the metabolism of even a single protein in any single animal, and practically nothing of the transformations of proteins in a suckling mother and of the metabolites that may be discharged in the milk under abnormal or even normal conditions of nutrition. It would be interesting to have an analysis of the milk in other animals giving suck while consuming excess of proteins. Experiments have been made which show that the metabolic machinery of adult rats works in a different way from that of young rats. Grown rats fed on one protein, gliadin, with the other essentials of a diet, remain active and healthy and capable of reproduction. The offspring appear normal and grow actively as long as they are suckled by the mother, but if after weaning they are fed on the same diet as the mother, growth ceases at once. The young animal would seem to be unable to manufacture something which is present in the maternal pabulum, and which is not present in the constitution of the directly-fed gliadin. Once the growth stage is over, some new machinery must arise capable of transforming the gliadin.

FIBROMA OF THE OVARY.

ACCORDING to Dr. Edmund D. Clark and Dr William E. Gabe[1] of Indianopolis, who record a personal case in a single woman aged 46, fibroma of the ovary is a sufficiently rare condition to warrant the publication of all carefully studied cases. They quote statistics derived from various sources showing the surprisingly small number of true ovarian fibromata encountered in large clinics or by men with an extensive experience of pelvic surgery. Only three examples were found by Sir Spencer Wells among 1200 ovariotomies. Kelly, in 1200 laparotomies, found only four cases, and Hellman reported only six instances among 4500 pathological specimens at the Woman's Clinic at the Berlin Charité in the course of ten years. Hellman and Reel estimate that fibromata constitute approximately 2 per cent. of all ovarian tumours. They occur from the time of puberty up to an advanced age, the youngest case on record being in a girl aged 17 and the oldest in a woman of 73. The majority occur in single women and about the menopause. Their size and weight vary extremely, the smallest ones being enclosed in ovarian tissue, while the larger ones weigh as much as 56 pounds. Their consistency is also very variable, some being composed of a loosely woven network of connective tissue, while others are so dense that a bone saw is needed for their section. They are liable to various changes, such as œdema, necrosis, hyaline formation, and fatty degeneration. The diagnosis is dependent solely on microscopical examination, which in typical cases shows a certain regularity of the individual fibres or muscular cells and strands, despite varying quantities of cells, fibres, vessels and degenerative changes. The principal feature in the symptomatology of ovarian fibroma is the presence of a hard, unilateral movable tumour, accompanied by ascites. Pain is of varying degree and is often absent altogether. Other symptoms, such as frequent micturition, constipation, &c., are due to mechanical factors. Owing to its absence in other tumours of the ovary and its rarity in fibromata elsewhere, especially in the uterus, the occurrence of ascites is of considerable diagnostic value. The prognosis of ovarian fibroma is invariably good. Treatment is exclusively operative.

POST-GRADUATE MEDICAL STUDY.

A RECENT newspaper announcement has reached this country of a scheme of medical amalgamation, rendered possible in New York by private munificence, whereby the medical faculty of Columbia University has been able to amalgamate with the Presbyterian Hospital, which is one of the largest hospitals in the city. Those who are familiar with the medical institutions of New York will be able to appreciate the comprehensiveness of the scheme, for which the claim has been made that, in point of size and equipment at least, a medical centre has been created which will be "the greatest in the world." The organisation thus brought into being has been endowed to the extent of £3,000,000—

---

[1] Proc. Soc. Exp. Biol., 1921, xviii., 167.

[1] Amer. Jour. of Obstetrics and Gynecology, March, 1921.

a sum provided, in several instances anonymously, by a few wealthy families of the United States; the donation of one contributor amounted to £1,000,000; a site, anonymously presented, was valued at a quarter of a million. The bestowal of sums of this magnitude marks a high order of philanthropy, for it brings no material gain to the donor, whilst enormously benefiting the community. *In this country a minimum sum of £30,000 is needed* in order to place the Fellowship of Medicine Post-Graduate Medical Association upon a firm financial and imperial basis, and we trust it will not be long before some public-spirited benefactor comes forward to render possible a medical enterprise of vital importance. In most instances of generosity similar to those we have mentioned, it may be assumed that the undertaking in question has been ventilated, and its value emphasised, before the evocation of so admirable a response; in other words, the needs of the Post-Graduate Medical Association of the Fellowship of Medicine must be clearly and repeatedly stated, both by the spoken and the written word. Individual effort must be brought to bear; with such a meritorious end in view an extended appeal can hardly fail of its effect. The novel form of requirement may cause some possible donors to hesitate, but it is just as likely to attract others by its novelty. In this connexion it is gratifying to note the increasing number of post-graduates joining the Association, particularly as the later summer, most usual and favourable time of year for post-graduate courses, has not yet come. The augury is for a successful session. It may, perhaps, be repeated that the sum of £30,000 for which the Fellowship of Medicine appeals is the minimum amount required to set the Post-Graduate Medical Association in a position worthy of the country which will reap the benefit of its activities.

ARSENOBENZOL IN SYPHILIS.

Dr. Joseph Nicolas, of the Lyon School of Medicine, gives an excellent summary of the treatment of syphilis in the *Journal de Médecine de Lyon* for April 20th. He prefaces his article with the following dicta: 1. That the arsenobenzol compounds afford the best treatment of syphilitic lesions not only from the point of view of cure but also from that of prevention. These may be supplemented by mercury in cases of intolerance, of resistance to arsenical treatment, or where such treatment is not available. 2. That when the lesions have disappeared under the influence of these injections it is necessary to submit the patient to a treatment which is methodical, regular, and of long duration, such treatment being intense during the first years and moderate during the later years, but in all cases being carried out over a considerable period—four to five years or even longer. 3. That the Wassermann reaction is a sign without any absolute value, which taken alone affords no guide to treatment. To await the return of a positive reaction before continuing treatment is to indulge in an absolutely unjustifiable opportunism.

After discussing the advantages and disadvantages of various arsenobenzol compounds and the different methods of administration of mercury, the author gives a standard table of treatment extending over a period of five years. Following this is a summary of treatment suitable for special cases. Cases of albuminuria are to be carefully investigated from the point of view of renal function before undergoing treatment. In cases of severe renal disease treatment with arsenobenzol compounds must be absolutely proscribed, the author quoting a case as an example in which uræmic coma was precipitated as the result of a single injection of 0·15 g. of novarsenobenzol in a patient suffering from renal tuberculosis. He considers that arsenical compounds are in any case less irritating to the kidneys than mercury, and on this account afford the treatment of choice in syphilitic albuminuria. Lesions of liver are of still greater importance from the point of view of treatment. As a general rule it may be said that no arsenobenzol compounds should be given when the liver is diseased. Reliance in such cases should be placed on mercurial treatment. Arsenobenzol injections must be immediately abandoned on the appearance of jaundice. If, however, jaundice has existed before commencing treatment, or after the first injection (possible Herxheimer reaction), the prohibition of novarsenobenzol need not be absolute, but only very small injections should be given, and a careful look-out kept on the patient. Laryngeal symptoms also necessitate special precautions, especially when there are indications of œdema and stenosis. In such cases a preliminary course of mercury must be administered, preferably intramuscular injections of biniodide or intravenous injections of cyanide. When some improvement in the condition of the larynx has been obtained arsenical treatment may be instituted.

Discussing the treatment of *ocular syphilis* the author remarks on the innocuousness of the arsenobenzol compounds compared with atoxyl from the point of view of bulbar neuritis. After having given 120,000 injections of arsenobenzol he has only come across one case of optic neuritis, and there was nothing to prove that this was due to novarsenobenzol. In the treatment of neuro-syphilis the author prefers intravenous injections of novarsenobenzol. Small doses should be given, and on no account must the slightest reaction be provoked; *deplorable results* follow the employment of doses producing a reaction. General paralysis is not affected at all by treatment. In the treatment of pregnant women he again uses small doses of 0·15 to 0·3 g. of novarsenobenzol, and in cases of intolerance intravenous injections of cyanide of mercury. As a routine treatment for syphilitic babies he prefers mercurial inunctions. When a rapid action is necessary he recommends intravenous injections of novarsenobenzol, 0·01–0·025 g. per kilo of weight. However, he considers arsenical treatment in infants not without danger and regards it as expensive. When an apparently healthy child is born of parents known to be syphilitic, the author pays special attention to the appearance of the placenta; if this is voluminous or shows signs of disease he institutes treatment of the child even in the absence of any signs of congenital disease.

Dr. Nicolas's summary of treatment emphasises two points: first, that novarsenobenzol compounds are the medicaments of choice in antisyphilitic treatment; and second, that such treatment must be continued over a much longer period than is generally recognised in France.

THE FRESH AIR CULT.

THERE are probably few medical men to-day who are not convinced of the value of an open-air life, in so far as this is practicable, in building up the individual resistance to infection, more especially in the case of children and of young adults. At the Congrès d'Hygiène Scolaire de Langue Française, which took place in Paris early in April, one of the subjects discussed was that of open-air schools, mainly for pre-tuberculous subjects and for children suffering from tuberculous *adenitis* and from latent tuberculosis. Various aspects of these schools were emphasised by the different delegates, one speaker, for example, pointing out that much more use could be made for this purpose of the open spaces in large towns. Another dwelt on the importance of a carefully graduated course of heliotherapy in each individual case, the duration of exposure being increased till the child can be left in the sun for many hours in the day; he had seen astonishing results on the physical condition, the powers of resistance, and even on the character. Yet another delegate recalled how a year previously the speakers at a meeting of the Society of Public

Health expressed a dread lest a catastrophe, such as the occurrence of a fatal case of broncho-pneumonia should kill the new venture of open-air schools, whereas as a matter of fact the pupils at these particular institutions had shown an extraordinary resistance to catarrh and infection of all kinds. The effect of an open-air life in increasing the weight is shown by Dr. Mestrezat in the March issue of the *Revue d'Hygiène*. The particular case described at some length is that of a healthy medical man of 32, whose average weight in Paris in 1914 was kg. 54·5, rising in 1915, when he was living an open-air life and taking daily exercise, to 58·1; falling again gradually to 56·1 in 1915–16 when living in a country town with three hours exercise daily; and falling again steadily to 54·6 in 1921 on resumption of life in Paris. Other instructive tables given by the same writer deal with the rapid and progressive gain in weight of soldiers convalescent from chicken-pox and mumps under the open-air treatment, the diet being the ordinary army rations in no way modified. After all this it is something of a shock to find in the March number of the *Archives de Médecine des Enfants* an article dealing with the treatment of the pre-tuberculous state in children, in which the writer deprecates open windows at night for such cases, quoting and endorsing the opinion of another medical authority as to the disadvantages in the shape of coryza, bronchitis, diarrhœa, and conjunctivitis which more than counterbalance any possible advantages to be derived from the practice. After hinting that most of the doctors who prescribe the treatment do not practise it themselves, he adds that in summer, during the hottest months, the windows may be partly open during sleep provided that there are curtains or blinds that can be drawn, but the warning is added "Il faut veiller surtout ce que l'air n'arrive pas directement sur le lit de l'enfant." This echo of past teaching contrasts strangely with the almost unanimous opinion in the medical world of to-day as to the value of fresh air in health and in sickness. "There's night and day, brother, both sweet things"; and it is surely time that the phantom-bogy of the danger of night-air should be laid once and for all.

DILATATION OF THE ŒSOPHAGUS *WITHOUT STENOSIS.*

DILATATION of the œsophagus in the absence of any anatomical stenosis has aroused considerable attention during the last few years, especially since skiagraphy and the use of the œsophagoscope has rendered its diagnosis a matter of comparative ease and certainty. Enormous dilatation may take place with almost total inability to swallow, producing complete failure of health and even death, and yet there is no obstruction whatever. A full-dress debate was held on the subject a couple of years ago at the Laryngological Section of the Royal Society of Medicine,[1] accompanied by an excellent series of pathological specimens, but it cannot be said that the ætiology has been finally explained. Certain points are established—namely, that food is arrested at the level of the diaphragm and not at the cardiac orifice, that there is no hypertrophy of the cardiac sphincter, and that the muscular wall of the gullet is not atrophied but rather hypertrophied. All records of cases of this affection are therefore of interest, though one of the most recent contributions, a paper by Dr. R. Bensaude and Dr. G. Guénaux, of the Hôpital Saint-Antoine in Paris,[2] also fails to clear up the doubtful points in its causation. Referring to the ease of diagnosis due to modern methods, the authors state that one of them, who had only seen one case in 15 years, has now diagnosed 17 cases in 18 months. Of these 17 cases 12 were females, and the neurotic element was an evident factor, the influence of the emotions during the war being very manifest. The age-incidence was very variable, two cases beginning in childhood, one of them at the age of 6, but the majority occurring between the ages of 33 and 55. The symptoms are fairly constant, with a slow insidious onset, a sensation of arrest of food at the lower part of the gullet, eructations, rumination, inability to take certain foods, regurgitation, vomiting, cough, dyspnœa, and periods of complete occlusion. The vomiting is without nausea or effort, and suggestive of the overflow of an over-full vessel. On X ray examination the opaque substance is arrested above the diaphragm, and gives a very characteristic cylindrical shadow ending in a regular finely-pointed extremity. On œsophagoscopy the dilatation is evident, and the entire wall, from top to bottom, is arranged in transverse folds; the aspect of the cardia is variable; the genu-pectoral position is recommended for this examination. Unfortunately none of the seven cases described are uncomplicated cases of idiopathic dilatation.

RADIOGRAPHY IN OBSTETRICS.

A SERIES of remarkable radiograms, published by Prof. Sebastián Recasens in the February number of *La Clinica Castellana*, brings forcibly to the attention the many possibilities of radiography in the field of obstetrics. There is, for example, the problem of the twin pregnancy, up till the present rarely diagnosed with certainty except by the detection of two sets of fœtal heart sounds beating in distinct rhythms. Not only does X ray assistance settle this problem, but it goes further and displays the relation of the twins to each other and to the maternal pelvis. There are numerous ante-partum conditions which may be revealed with certainty by this method to the great assistance of the obstetrician; among such may be mentioned fœtal deformities, hydrocephalus, and the various degrees of extrusion of the fœtal head. Prof. Recasens challenges the accepted view, expressed in all text-books (and copied, so he says, from one to another) that the fœtal limbs in utero are normally completely flexed. The published radiograms seem to bear out his contention.

SIR FREDERICK BANBURY'S REASONING.

IN moving the second reading of the Dogs Protection Bill Sir Frederick Banbury extracted from a series of editorial articles which appeared in THE LANCET some two years ago one line, which means nothing without the context, but on the strength of which he seems to have claimed our support for his contentions. For future quotation in any reasoned speech he may make on the subject we bring to his notice our considered opinion on the Bill, as expressed in the closing sentence of one of the articles which he may be supposed to have consulted already. "The limitations which are intended to be put upon medical research may bear sad fruit when this readiness to put sentiment and sensibility ahead of sense and truth will not appear such a humane proceeding as many now consider it to be."

WE regret to announce the death on June 2nd of Dr. John Matthew Fortescue-Brickdale, physician to Clifton College and the Bristol Royal Infirmary, and an authority on pharmacology.

DR. E. G. Graham Little has been elected by the graduates of medicine and surgery of the University of London to serve a fifth term of office as representative on the Senate.

CONTROL OF VENEREAL DISEASE.

County Councils and Venereal Disease: An Official Circular.

The Government, as is well known, have had under consideration the policy hitherto adopted in this country for dealing with venereal diseases, and the question whether any modification of that policy is required at the present time. The outcome of this consideration is the issue by the Ministry of Health of a circular (No. 202), dated May 31st, 1921, dealing as follows with the present position of the prevention and treatment of venereal diseases.

Basis of the National Scheme.

As the Council are aware, the national scheme for the prevention and treatment of these diseases is based upon the recommendations contained in the Final Report of the Royal Commission on Venereal Diseases. The main recommendations of the Commission were: 1. That gratuitous treatment for persons suffering from these diseases should be provided at hospitals and other institutions in all parts of the country. 2. That a widespread campaign of publicity and education as to the dangers and effects of these diseases, and as to the necessity for early and skilled treatment, should be undertaken. These recommendations have been and are being carried out under schemes formulated by the Councils and approved by the Minister of Health or his predecessors, while the propaganda campaign, in accordance with the recommendation of the Royal Commission, has been directed, centrally by the National Council for Combating Venereal Diseases, under the supervision of this Department, and locally by the County and County Borough Councils, a large number of which have coöperated with the local branches of the National Council in carrying out measures of publicity and education. In a few areas, also, Ablution or Disinfecting Centres have recently been instituted as an experimental measure in order that facilities may be provided for the disinfection, by skilled attendants acting under medical supervision, of persons who have exposed themselves to the risk of infection with these diseases.

War-time Experience.

The experience gained during the war by different armies in attempting to prevent the spread of venereal diseases has given rise to question whether, in the case of the civilian community, some further measures should not be adopted with a view to diminishing the incidence of these diseases, and after the conclusion of hostilities this question was considered by an Interdepartmental Committee appointed by the Minister of Health. This committee came to the general conclusion that although certain drugs, if properly and skilfully applied, are efficacious in preventing venereal diseases, the most carefully organised system for the supply of these drugs in "packets" and the instruction of men as to their use, did not produce such a general reduction in the incidence of these diseases as to warrant its recommendation by the Government. It was, however, found that where preventive treatment was provided, after exposure to the risk of infection, by a skilled attendant, the results were better than when the same measures were taken by the individual affected, even after the most careful instruction. Unofficially also this question has recently been under consideration by a special committee of the National Birth-rate Commission, and the conclusions of that committee are contained in a report which has now been published.

The Question of Self-disinfection.

The Government have given careful consideration to the question on which the views of these two committees, official and unofficial, are not completely in accord—namely, the question of self-disinfection—but they find that there is general agreement on the following conclusions: 1. That the best way to avoid risk of venereal disease is to abstain from promiscuous sexual intercourse, and that a steady and continuous policy of public enlightenment on this point, and as to the risks of venereal disease and its resulting consequences on the general health of the community, is essential. 2. That disinfection immediately after exposure to risk of infection is effective only to the extent to which it can be thoroughly and intelligently applied in the particular case. They also find that medical opinion is divided on the question of the efficacy of self-disinfection for the civilian population, and in particular on such questions as (1) whether it is practicable to give such instruction to the population generally as will ensure that the disinfectants are thoroughly and skilfully applied; (2) whether the spreading of knowledge as to the efficacy of disinfectants would not lead to persons running the risk of infection who would otherwise avoid that risk, and thus increase the spread of disease; and (3) whether the disinfectants will not be used in some cases for the treatment of developed disease with the result that proper treatment will be delayed and the cure of the disease rendered more difficult and uncertain.

The actual situation which confronts the Government is that there is not unanimity of opinion on the medical side as to the practicability and likelihood of success of self-disinfection for the civil population, whereas on the moral and social side most weighty objections are advanced against it. It is clear that this question is one which cannot be decided solely by reference to medical opinion—moral and social considerations of very great importance are involved in it. In the circumstances the Government have decided that they cannot give official support to self-disinfection as a policy.

Public Instruction.

The decision of the Government emphasises the importance in the interests not only of the individuals concerned, but also in those of the community in general, of continuing and extending public instruction and enlightenment as to the dangers arising from promiscuous sexual intercourse, and the disastrous consequences on the general health of the community which result from the spread of venereal diseases. The Minister is aware that in most parts of the country a wisely directed campaign has been, and is being, carried on in this direction, and he is advised that it is essential that no opportunity should be lost of educating public opinion on this matter. It is important that the Council should call to their aid every available agency in their area which exists for the purpose of the moral and social betterment of the people, and the assistance of voluntary organisations of this kind should be most valuable in advising as to the lines on which a campaign of publicity and education can best be directed and as to the contents of such leaflets, posters, &c., as the Council may issue. It is essential that due economy should be exercised in this matter as in all other public services at the present time, but the Minister trusts that the Council will not curtail their expenditure during the current financial year on educational and propaganda work in connexion with these diseases, and he is prepared, as indicated in paragraph (6) of Circular 192, to consider applications for his approval of limited expenditure for this purpose in excess of that incurred by the Council during the past financial year. This is a matter also in which the Council would be justified in looking to voluntary bodies for some financial assistance.

Issue of Warning Leaflets.

The question of the contents of any publications which may be issued by the Council on this subject is one for the decision, in the first instance, of the Council, but the Minister desires to suggest the advisability of the widespread issue of leaflets, &c., warning the public of the dangers of venereal diseases and containing advice on the following lines:—1. The prevalence of venereal diseases is a grave source of danger and ill-health to the public. 2. These diseases are usually contracted through promiscuous sexual intercourse, and the best way to avoid risk is to avoid such intercourse. It is the duty of all individuals who have incurred, or think they have incurred, the risk of contracting disease, to cleanse themselves thoroughly and immediately, and thereby diminish the risk. 3. If any signs or symptoms of disease, however slight, are experienced the individual should promptly seek medical advice or attend a venereal diseases clinic. 4. Any attempt at self-treatment of these diseases is likely to be disastrous.

Ablution Centres.

The Minister is of opinion that the arguments which have influenced H.M. Government in deciding against any official advocacy of self-disinfection do not apply to the provision of ablution centres where facilities are provided, with proper safeguards, for disinfection by skilled attendants acting under medical supervision. The experience so far obtained is not sufficient to enable any final conclusions to be drawn as to whether such ablution centres should be established permanently in large towns; but the evidence available as to the results obtained in different armies from the provision of these centres justifies further experiments of the same kind for the civilian population, and the Minister is accordingly prepared to consider applications for his approval of the experimental provision of further ablution centres.

Legal Position of Chemists Selling Disinfectants.

It is understood that questions have arisen as to the precise effect of section 2 (2) of the Venereal Disease Act, 1917, and the Minister considers it desirable to state that, although he is not empowered to give an authoritative interpretation of the provisions of any Act of Parliament, he is advised that a chemist does not commit an offence by selling any substances for which he is asked, merely because those substances are capable of being used as disinfectants against venereal diseases, so long as the substances are not sold accompanied by any written or printed recommendations or instructions as to use. It should be carefully borne in mind that by sections 1 and 2 (1) of the same Act, an offence is committed by any person (other than a duly qualified medical practitioner) who for reward direct or indirect, treats, prescribes for, or offers advice in connexion with the treatment of venereal disease, and by any person who does any of these things or even offers to do them, by advertisement, public notice, or announcement.

It will be seen that the official circular has the merits and the limitations which could have been foreseen from the announcement in the House of Commons made by the Minister of Health on the vote to meet the expenses of the department.[1]

INTERNATIONAL LABOUR COÖPERATION.

At the recent International Congress of Transport Workers, held in Geneva, a discussion arose on the treatment of venereal disease amongst seafarers, and a resolution was passed calling upon the executive to initiate a movement in favour of international legislative measures, and to enter into negotiations with the International Organisation of Shipowners with the object of giving effect thereto. On the suggestion of Mr. Walter Clarke, chief of the Division for Combating Venereal Diseases of the League of Red Cross Societies, this resolution was transmitted to the Office International d'Hygiène Publique for its information. In forwarding it, Lieut.-Colonel T. F. Ritchie, assistant chief of the same Division, writes:—

> "I think it is very encouraging to see that the transport workers themselves realise the importance of providing treatment for seafarers, and that they wish to initiate international legislative measures in regard to venereal diseases."

We hope that the example set by the Transport Workers' Federation will encourage other industrial bodies to take similar action within their own borders. More good will come of it than from any external attempt to impress such suggestions upon their members. The holding without delay of an international anti-venereal congress would afford the required opportunity for the other industrial federations to be represented and to take appropriate action.

SOCIETY FOR THE PREVENTION OF VENEREAL DISEASE.

The second annual meeting of this Society was held on June 6th at the house of the Royal Society of Medicine, Lord Willoughby de Broke, the President, in the chair. The President said that venereal disease was still proceeding at such an alarming rate as to be a great public danger. The official policy of exhorting the public to be chaste and advising them to consult a doctor when infected had not succeeded in preventing its spread. The circular recently issued by the Ministry of Health stated that it was the duty of all individuals who had incurred the risk of infection to cleanse themselves thoroughly and immediately in order to diminish the risk. The President urged that this statement affirmed the Society's policy of self-disinfection, though the Government would not take responsibility for the official issue of disinfectants accompanied by instructions. He moved a resolution recommending formal application by the Society to the Ministry of Health for sanction for the preparation and sale, under the supervision and control of the Society, of materials for immediate self-disinfection. This resolution was seconded by Lady Askwith and was carried. The hon. secretary, Mr. Wansey Bayley, in submitting the annual report, said that the number of county and borough councils which had adopted the Society's policy had increased from 12 to 20.

ROYAL INSTITUTE OF PUBLIC HEALTH:

CONFERENCES ON PUBLIC HEALTH PROBLEMS.

ON June 2nd, at the Guildhall, a series of Conferences on various questions concerning the health of the nation was opened by H.R.H. the DUKE OF YORK. In welcoming the delegates His Royal Highness said that the work of the Conferences was of national and international importance, and that the immense significance to the nation of such questions as the support of voluntary hospitals and the improvement of housing conditions could not be too much emphasised. Other matters of vital importance to the community were venereal disease and tuberculosis. As President of the Industrial Welfare Society he took great interest in the subject of the Session dealing with the necessity for greater attention to the maintenance of efficiency and the prevention of ill-health in industry. Industry had too long been carried on without thought of its effect on the worker, and it is good, he said, that the questions of industrial physiology and psychology and vocational aptitude should be seriously discussed. The future prosperity of the country was bound up with the establishment of a healthy, happy, and contented industrial army.

The LORD MAYOR on behalf of the City of London, having welcomed the delegates,

Sir ALFRED MOND, the Minister of Health, moved a vote of thanks to the Duke of York, who, he said, was following the great traditions of his House by taking the keenest interest in the public health of the country.

Lord LEVERHULME seconded, and the Duke of York in his reply expressed his appreciation of the honour which had been conferred upon him in being made an Honorary Fellow of the Royal Institute of Public Health.

MUNICIPAL HYGIENE AND VOLUNTARY HOSPITALS.

Lord BURNHAM, who presided over the session on Municipal Hygiene, said that the Conference was not only opportune but necessary in connexion with the administration of the Poor-law and the future of voluntary hospitals. The whole system of local administration had to be considered, for there were no longer any scientific frontiers of local government; they had disappeared in the cataclysm of the great war, while the welfare of the community depended upon the health of its individual members. Some people believed that the transformation of the Local Government Board into the Department of Public Health meant only a change in name, but that there had really been a change in Parliamentary attitude and consideration was shown in the fact that the Minister of Health was on the platform that morning. The real problem of public health was how to link up the various health services and health institutions with the system of national insurance. The great defect of the National Insurance Act was that it ignored the existing services and institutions from the financial and administrative points of view. The voluntary hospitals were primarily intended for the treatment of the sick poor, but in their development they had become of even greater importance as places of original research and for educating those who served the cause of health. While the hospitals were overcrowded the Poor-law infirmaries were half empty and not brought into relation to the rest of the health services. He hoped that all the hospitals and infirmaries would be coördinated for public welfare, and that ways and means would be secured from the insurance funds.

Major W. ORMSBY-GORE, M.P., in opening the discussion, said that one of the problems to be discussed was the administrative separation of preventive from curative medicine. The Poor-law system owed its origin to the reaction against a state of affairs that had been allowed to grow up since the reign of Elizabeth. The basis of the present position was the Metropolitan Act of 1867, which established State-provided infirmaries, and as a result there were to-day in Poor-law institutions 94,000 beds. In London the beds in these institutions were more numerous than those of the voluntary hospitals. In order to bring about coördination legislation was necessary, but before that could be obtained public opinion would have to be developed both inside and outside of Parliament. There should be a general demand that not only should the Insurance Act, and all the work in connexion with that Act be brought into line with the work of voluntary hospitals and State-provided hospitals, but that all curative treatment should be considered as a whole. That would include private nursing homes. Whatever happened to voluntary hospitals the whole question must be made a national and not a local matter. It was vital to the progress of medical science that the voluntary system of hospital support should be autonomous and under the control of the Ministry of Health.

---

[1] THE LANCET, May 21st, p. 1088.

Prof. E. W. HOPE (M.O.H., Liverpool), while realising the good work that had been done by boards of guardians, said the infirmaries were not being utilised to their capacity and the voluntary hospitals were closing. It would be a disaster to the country if the voluntary hospitals were placed upon the rates.

Councillor WILSON (Liverpool) said it was a mistake to place the charge for the upkeep of voluntary hospitals on National Insurance funds. The money would have to be found either in higher charges upon incomes, or in complete reassessment of profits and so forth, and not out of the pockets of working people.

Mrs. BRYCE (Chairman of the Public Health Committee, Hackney) said that very little would be done until children and parents were properly housed, fed, and trained.

Dr. H. C. PATTIN (M.O.H., Norwich) thought that hospitals should be provided for directly from the Exchequer. The health of the people was the first consideration of the State.

Mr. H. L. WOOLLCOMBE (Secretary to the Charity Organisation Society) appealed for the continuation of the voluntary system, and hoped that a large number of the Approved Societies would follow the splendid example of the National Deposit Friendly Society in contributing towards these institutions.

Sir WILLIAM SMITH expressed the opinion that Poor-law hospitals should be made generally available for public use, the arrangements enlarged, and a staff of honorary medical officers added.

Miss MOTT said that the National Insurance Act was very unpopular because people did not get value for their money.

Dr. J. HOLROYDE (M.O.H., Chatham) shared the common feeling against State interference, but already, he said, the thin end of the wedge had been introduced; for public funds were received by hospitals, for school children, infants, maternity and child welfare centres, venereal treatment, and for other purposes. At the Chatham local hospital a scheme of graduated payments had been initiated with some success, and had received the support of labour and trade councils.

A representative of the National Labour Housing Council asked that a larger share of the management of hospitals should be given to the working classes or their representatives.

Mr. C. F. PEYTON BALY (British Dental Association) said it was not possible to separate preventive from curative work, and any scheme that was drawn up must take proper account of preventive medicine. Full provision would have to be made for the training of young doctors as well as for keeping qualified men up to date.

Councillor BULLEN (West Ham Board of Guardians) maintained that treatment in infirmaries was just as skilful as that given to patients in other hospitals.

The Housing Problem.

In the afternoon Sir GEORGE MCCRAE (Chairman of the Scottish Board of Health), who presided over the Session on the Housing Problem in its various bearings, said that at the present moment there was a world shortage of houses—it existed at home, in our colonies, all over Europe, in America, and in Asia. That house shortage was not due to the war, because, though the war had intensified the situation, there had been a great falling-off in house building all over the world before the war. He gave facts and figures in support of this view, and asked whether it was not a question for our legislators to consider whether they had really got to the root cause of the housing difficulties. While many grumbled at the slow progress that was being made in house building, those who knew the magnitude of the difficulties in the way realised that progress had been made. Having regard to falling prices and the augmentation of the supply of labour, he thought the future would see further and economic progress.

Colonel F. E. FREMANTLE, M.P. (Chairman of the Housing Committee of the London County Council), confining his remarks to London, dealt with the need for housing and the provision that had been made. The needs increased year by year. It was necessary to provide a margin of empty houses so as to supply accommodation for that portion of the population who moved in accordance with the constantly changing and developing needs of the community. Then there was the matter of overcrowding, the standard according to London County Council requirements being not more than two adult persons in one room. Quoting figures as to rents, he said the Government would have to bring out a new scheme for housing. Before the war the housing schemes under the County Council were self-supporting, and he maintained they should be self-supporting again; but, in the meanwhile, the Government must provide some money. The great insanitary areas that had long been known would have to be dealt with. The population of London should not be encouraged to go further away and provision should be made for new industries near to their houses.

Mr. TREVELYAN THOMSON, M.P., said it was an impossible proposition now to hold our hands from the housing scheme of 1919. There were suggestions that the need was not now so great. Deplorable conditions, he said, existed at Middlesbrough, 15 to 18 people living in two rooms. In the interests of morality, public health, and true economy he asked the Conference to say that there should be no cutting down of the housing programme.

Mr. TOM MYERS, M.P., and other speakers having taken part in the discussion,

Councillor WILSON and Mr. J. S. WHYBROW (Secretary of the Labour Housing Association) moved and seconded the following: "In view of the continued shortage of houses and the evils of overcrowding, this Conference expresses its opinion that in the interests of public health no relaxation should take place in the efforts which are being made to increase the immediate supply of houses." The motion, after some discussion, was carried.

Industrial Efficiency and Health.

At the morning session on June 3rd Lord LEVERHULME, the President, in an introductory address said that we must get things done or be undone. Nothing, however, could be done except on the basis of robust health. He thought that one of the secrets of past success in this country was the apprenticeship system. In these days close contact between master and men was impossible. The system of granting doles for unemployment was a pernicious one. There were only two periods in the life of a human being when allowances and doles could be wisely given—before about the age of 16 and after the age of 70. Any dole given for the better education and healthy upbringing of young people was good, and the country owed something to those who were past work; but doles to the healthy and strong would prove a curse. On the mechanical side of production, in factories employers sought the aid of well-trained engineers, but for the most complex machine of all, the human worker, no educational engineers were employed.

Prof. E. L. COLLIS dealt with the necessity for greater attention in industry to the maintenance of efficiency and the prevention of ill-health. He said that it might fairly be claimed that the most important of all subjects had been specially referred to by the Duke of York when he said that industry had been carried on too long without thought of the workers' health. In the interests of production industry was generally quick to seize upon anything which made for increased output, and he maintained that attention to the vocational selection of the worker was a primary need for the prevention of ill-health. The State was taking steps to bring up healthy adolescents, so that they might be useful citizens and productive workers. Industry had a duty to maintain them in health and efficiency and must provide hygienic conditions of work in order to acquire a stable personnel, to increase efficiency, and to pay high wages out of good results. Medical supervision, which might take the form of a medical department in the establishments, was a sound investment, and was a means of maintaining efficiency and preventing ill-health. Facilities for convalescence among industrial workers were needed to expedite recovery, and when linked up with re-education, as was done by the Ministry of Pensions, could reclaim many useful workers from the ranks of the unemployable.

Mr. KENNETH LEE (Manchester Cotton Industry) said that far too much money was spent on hospitals for cure and far too little on prevention. Sufficient precaution, at any rate at an early age, was not taken to see that young people on entering a factory were suitable for the work to which they were put. Bad teeth, too, were a serious cause of ill-health.

Mr. J. HODGE, M.P., said that if Capital had done its duty towards Labour there would have been no necessity for discussion that morning. The worker must be treated not as a "hand" but as part of the organisation for the production of wealth.

Sir FREDERICK MILLS said that no nation could prosper when its industries were constantly subjected to sudden stoppages, for industry in these circumstances was incapable of properly carrying out its engagements. Population was dependent upon industry and not industry upon population. The history of this country showed that the population for centuries on had varied between five and ten millions. Sometimes we had our civil wars, and the population went down suddenly, gradually grew, and on the introduction of steam in the middle of the eighteenth century began to advance by leaps and bounds. Industry made population. There was only one cure for industrial unrest. The workmen should become shareholders in the companies they worked for. Working-men directors on the boards of the companies were needed.

Prof. Sir THOMAS OLIVER (Durham) said that efficiency in occupation could only be secured by the worker himself being healthy, and by labour being carried on under healthy conditions. The healthiest occupation was that which was carried on out of doors, as seen in the low mortality rates of the farming classes. In this respect the oldest occupation occupied the prime position.

Dr. H. M. VERNON (Investigator for Industrial Fatigue Research Board) agreed with all that had been said as to the importance of prevention of ill-health in the industrial workers and the effect of ill-health on efficiency. The results of investigation had shown that long hours and overwork produced sickness and inefficiency. There was a lack of investigators and many employers failed to realise the bearing of research work of the kind he referred to on health and therefore on efficiency.

Dr. RHODA ADAMSON (Clinical Lecturer in Obstetrics in the University of Leeds) recounted her experiences in examining and supervising women war-workers, which showed the advantage to employers of labour in regulating the employment of women by medical advice. From the point of view of health there was very great neglect among the working women of the country. Proper attention to eyes and teeth saved a great deal of sickness, while putting women on light work during pregnancy was economical both to master and worker.

Prof. F. SCHOOFS (Liége) pleaded for the establishment of a connexion between engineering and the medical sciences in the university curriculum.

Venereal Diseases.

The BISHOP OF BIRMINGHAM presided over a discussion on the present machinery for dealing with venereal diseases and the measures essential for effective prevention. He said that he could not understand the policy of the Ministry of Health in regard to venereal diseases, but he wished that the medical profession would show unanimity in their opinions. It would be a great help if the medical profession could pronounce whether disinfection before connexion was a certainty for the prevention of the disease. On the Committee with which he was connected there was difference of view, and the conclusion which the Government had reached was that, the evidence being contradictory, self-disinfection was not a certainty. He agreed that in a large proportion of cases it would not be quite satisfactory because the person who was using the method was not in a condition in which he—still more she—would be likely to take the proper precautions and do the right things. Discussing the moral and social aspects of the matter, he said that medical men appreciated the moral side of the question as well as the social, and pointed out that the disease was terribly destructive not only to the guilty but to the innocent.

Prof. E. W. HOPE said that though every facility was given in Liverpool for the treatment of venereal disease, there were great difficulties in the way of persuading those who had started treatment to continue with it. That led to a great waste of public money. Sixty per cent. of the patients attending the hospitals in Liverpool ceased to attend before they were free from infection. Of the patients attending at the Royal Infirmary there was a preponderance of men, a large proportion of whom were seamen, and among them many foreigners. The women patients formed about one-eighth of the whole. It was proposed to ask Parliament to consider a measure which would make larger provision for free treatment, would call upon those who were infected, and who knew it, to consult a medical man, and would impose on that medical man the duty of explaining to the patient the nature of the infection and the necessity for continuous treatment. Other provisions placed upon parents and guardians the duty of protecting, by medical guidance, young persons under their care.

Sir WILLIAM MILLIGAN (Lecturer on Diseases of the Throat and Ear in the University of Manchester) said that it was exceedingly difficult for any Government to act unless there was unanimity of medical opinion. This there would never be, but he thought the guiding principle should be the opinion of the majority. He did not believe that venereal disease would ever be swept out of any country. It would always exist to some extent, but a very great deal could be done to decrease its incidence and its ravages. Self-disinfection, in his opinion, was a snare, and often a cloak with a very great number of people for the continuance of vice. It was not practicable for the layman to disinfect himself, and particularly herself, without knowing a great deal about the anatomy of the parts. If the matter was going to be seriously tackled a large expenditure of money would be needed and provision would have to be made for ensuring that people should attend at clinics until cured. Young men and women before going out into the world should be taught something of sex physiology, and it must be recognised that the incidence of venereal disease was very much mixed up with the drink question.

Dr. H. J. SEQUEIRA (London Hospital) did not agree that self-disinfection was useless, and pointed out that it was easier to disinfect the glans penis than the very delicate conjunctiva of an infant. He thought that the measures at present in use were effective so far as they could be effective.

Prof. WINIFRED C. CULLIS (University of London) pleaded in the interests of the Mercantile Marine for clinics at every port, the provision of recreational facilities for men who wished to keep straight, and for educational propaganda.

Colonel C. J. BOND (Vice-Chairman of the Consultative Council of Medical and Allied Services of the Ministry of Health) said that all would agree that the present machinery for dealing with the disease was certainly defective on the preventive side. The Government had not yet recognised the value of the influence of the group mind and public opinion.

Mrs. SCHARLIEB (Royal Free Hospital) pleaded for a stricter control in the upbringing of persons of both sexes.

Dr. F. N. KAY MENZIES (Public Health Department, London County Council), describing the scheme which was in operation by the London County Council in controlling the disease, said that something like 40 per cent. of the patients ceased treatment before they were out of the communicable stage. There were great difficulties in regard to providing treatment at times which would suit all kinds of people, and it was proposed to make arrangements so that the clinics might be open all day. The cost of treatment in 1917 had been £33,000 ; in 1918, £50,000 ; in 1919, £80,000 ; in 1920, £100,000 ; and this year it would probably reach £120,000.

Lord WILLOUGHBY DE BROKE said that it was obvious that, in spite of exhortation and treatment, the present methods were inadequate, and that there was an increasing charge upon the ratepayers and taxpayers of the country. Everything possible ought to be tried.

Lady BARRETT, representing the Federation of Medical Women, said that unless it could be proved that self-disinfection, as used by the layman, was successful, it was not right to teach young people that they could obtain immunity by so using them.

Dr. MARIE STOPES said that the only cure for the deplorable state of things which existed was early marriage and control of conception.

Industrial Tuberculosis.

The proceedings on Saturday consisted of a debate upon the efficiency of the present machinery for dealing with tuberculosis, at which Sir ROBERT PHILIP, Prof. LYLE CUMMINS, Sir G. SIMS WOODHEAD, Dr. JANE WALKER, and Dr. F. J. H. COUTTS (Ministry of Health) were the principal speakers.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this society held recently, with Dr. L. E. V. Every-Clayton, the President, in the chair, various modern clinical methods were demonstrated. Drs. Patrick and Eric Watson-Williams showed a number of patients to illustrate the use of the Otorhinoscope. Dr. J. O. Symes and Dr. Cecil Clarke exhibited the apparatus used in the Fractional Method of Gastric Analysis, illustrating its action on two students. Dr. Geoffrey Hadfield gave an account of a simple plan for the estimation of blood-urea, and demonstrated the apparatus. Dr. R. G. Gordon showed a tuning-fork apparatus for the quantitative estimation of vibration sense, with a series of charts illustrating the value of the method in the diagnosis of nervous disease. Dr. Gordon also showed a patient with aphasia and described the tests applied in accordance with Head's theory. Dr. C. E. K. Herapath gave a brief account of the Polygraph and Dr. Carey Coombs of the Electrocardiograph.

INDUSTRIAL MEDICINE:

A CONFERENCE OF PRACTITIONERS.

A MEETING of medical practitioners engaged in medical service at industrial undertakings, called together by the Industrial Welfare Society, was held in the council room of the Society at 51, Palace-street, Westminster on June 2nd. The Conference was opened by H.R.H. the DUKE OF YORK, President of the Society, who spoke of the importance of the movement and wished success to the deliberations.

Medical Service in Industry.

Dr. R. McN. WILSON delivered the opening address, in the course of which he paid a tribute to the factory inspectors, who had been instrumental in removing the terrible conditions which formerly existed in our factories. If employers had listened to the factory inspectors and doctors, the trouble between labour and capital would have been healed 50 years ago. The work of fatigued or underpaid employees did not pay the employer. The medical profession was in an impartial position for demonstrating that the interests of capital and labour are identical. Here were enormous opportunities for industrial medicine. The human machine must be well "vetted." The medical profession should have a preventive outlook and adopt the "Mackenzie line of thought." Actual disease was an end process and we must study the processes which led up to it. Any successful system of industrial medicine must be based on the general practitioners who alone knew the conditions of the home and family and who alone had the necessary influence to convince his patient as to the need for following advice (for the benefit of his health) which often seemed distasteful.

Dr. T. M. LEGGE, of the Home Office, insisted that all industrial welfare work must be based on medicine. The movement for industrial "doctors" was only in its infancy. He would like to put some questions to the meeting. What was the relation of the "works doctor" to the panel doctor, to the certifying factory surgeon, to the welfare superintendent, and to the Whitley Councils ? Could they have a panel of works doctors, or could part-time industrial work be linked up with the panel system ? Were there clinics established in the works, ophthalmic, dental, &c ? Could they show to the employer results in £ *s. d.* from industrial medicine ? They were committed to the insurance system for weal or for woe. Medical examination of employees by the firm's doctor was not feasible, but might be done by State doctors, as under the present panel system. In the U.S.A. they had no insurance system to retard the spread of industrial medicine.

Dr. ARTHUR SELLERS pointed out that the certifying factory surgeon had not time to examine children properly. He (Dr. Sellers) had a panel himself. His practice was to examine selected cases in the ambulance room of the works and then refer them to their panel doctor. The panel doctor had no means of suggesting suitable employment for his patient. Certifying factory surgeons must have more time to do their work and should work more in touch with the industrial welfare doctor.

Dr. E. E. MATHER stated that he and a woman doctor worked "whole time" for Messrs. Cadbury. There were about 9000 employees, 1000 being under 16. They treated all who came for treatment, men, women, and children, and had no difficulty with the panel doctors. They had a dental clinic and the firm paid for special cases to be sent to hospitals and consultants. He had had two years' experience, but wished a special course of training had been available for him before taking up the work. The medical examination of existing employees was optional, but the examination of applicants was compulsory. There were very few rejections, not more than 1 per cent. perhaps. Some would be admitted conditionally on submitting to an operation for tonsils or obtaining a truss for hernia.

Dr. Wilson in his reply said the backbone of the whole system of medicine was the general practitioner. They must interest the general practitioner and bring him into the scheme of industrial medicine.

Health Problems in Industry.

At the afternoon session, Prof. E. L. Collis gave the opening address. He pointed out how welfare work had grown as the result of the war. In 1913 they could only muster about 20 welfare supervisors at a conference at York. There was no reason why medical service in factories should not grow equally rapidly, but propaganda work amongst employers was necessary. Medicine could save industry millions a year by preventing break-downs, lost time, by finding workers jobs suited to their health, and by making the jobs more healthy for the workers. Miners' nystagmus, lead poisoning, anthrax, and phosphorous poisoning were comparative rarities—the things they wanted to prevent were bronchitis and phthisis. The question is what is the best way of convincing industry of its needs.

Dr. E. Halford Ross instanced a firm of printers doing fine work which saved thousands a year by employing an ophthalmic surgeon. Medical supervision should go right through industry.

Dr. R. E. Cree showed graphs illustrative of accidents to groups of workers at the shipyard of Swan Hunter and Wigham Richardson. Boys, of course, had the most accidents. Old men were often disabled permanently by very trifling accidents, and suitable non-dangerous work should be found for them. He attended the ambulance room and treated accidents only for the firm. He knew that he saved the firm a great deal of money by preventing sepsis. There ought to be a system by which convalescents could do half time or light work suited to their condition.

Sir Thomas Oliver pointed out, as £ *s. d.* gain, that the match industry was now free from jaw and dental trouble. He thought there should be a State department for industrial medicine, as in France and U.S.A. Half-time work for convalescents would be very valuable.

Dr. J. R. Kerr, of St. Helens, spoke of the sheet and plate glass industry. Since 1907 the Pilkington firm had given him great support in finding medical equipment. The hospital was largely self-supporting. Firms and insurance companies paid towards the cost.

Dr. M. W. Renton, who had worked for Vickers, mentioned that this firm had a hospital and special clinics for electro-therapeutics and massage, &c., and that insurance companies send patients for treatment. The certifying factory surgeon should never be the "works doctor." The practitioners on the panel were often very hazy as to the exact occupation when they signed certificates and should attend the works clinic.

Dr. T. L. Llewellyn said that two years ago he got the North Staffordshire coal-owners to set up a massage centre. They had an attendance of 200 a week and had obtained very satisfactory results. He always wrote to the family doctor informing him that he was going to give his patient a course of treatment. He was certain the centre had more than paid for itself by getting men "fit" more quickly.

Dr. D. A. Coles acted as "works doctor" for the Gas Light and Coke Co. He was not on the panel himself, and had no difficulty with the panel practitioners. The men were always willing to be overhauled because they knew it was in their own interest. He endeavoured to get the cases early, examine eyes, provide trusses for hernia, &c. He hoped to get his firm to assist in dentistry and the provision of spectacles.

Mr. Seebohm Rowntree said that his firm had a works' doctor, a dentist assisted by mechanics, and an oculist. The cost was comparatively trifling. £2000 on a wage bill of £1,250,000. The establishment of a clinic was not costly like that of a canteen. Probably the Industrial Welfare Society would be the best body to do the propaganda work as to the value of medicine to industry.

Mr. R. R. Hyde, the Director of the Society, asked the meeting at the close to formulate a scheme for the continuation of the campaign initiated by the day's work.

Ultimately Dr. Coles, Dr. Mather and Flight-Lieut. F. J. P. Saunders were appointed a small sub-committee to draw up a programme to be put before another conference in connexion with the Summer School of the Industrial Welfare Society, which is to be held at Balliol College, Oxford, in September.

HYGIENE ON THE SEA.

ACCOMMODATION FOR SEAMEN IN SHIPS OF TO-DAY.

(By our Special Correspondent.)

VII.—P. & O. MAIL STEAMER.

A P. & O. mail steamer, ready to embark her passengers and go to sea, lies comparatively unnoticed among the other great ships at Tilbury, and that just shows how big is London, how small relatively are the great Eastern ports of the world. Here the ship is hardly noticed. At the other end of her voyage the whole port will be interested in her. Her arrival with the English mail, the London papers, passengers primed with the latest gossip from home, and the trunks of some of them full of the newest fashions, has been eagerly expected, and the day she does come in is something of a holiday, at any rate a "festa," even in Bombay or Hong Kong, busy ports that they are. London has a mail day every day, and the docks, though they stretch for 20 miles along the river, are far from the town or else perhaps the hard conditions of the sailors' life might sooner have been improved. Slums in Drury-lane are visible, and their cry for improvement is heard, slums beyond Wapping, who shall know of them.

It was by the kind permission of the P. & O. Company that I was recently taken down to Tilbury, on behalf of The Lancet, by Dr. Arnold Chaplin, medical superintendent of this and other companies, to see their ship *Malwa*. She was built ten years ago; her gross tonnage is 10,941; she can carry some 6000 tons of cargo, and has accommodation for 285 first- and 127 second-class passengers, 412 in all; she is 540 ft. long, 61 ft. broad, and draws 27 ft. when loaded. She has a ship's company of 340, of whom 101 are lascar firemen, 51 lascar sailors, and 67 Goanese stewards. The large saloon, kept cool by electric fans, and the spacious music saloon, the ladies' card-room, &c., make the travellers comfortable, while the large deck area outside shows the ship is built for the tropics, and to get for her passengers all the coolness there may be. The cabins are of the usual pattern, and of them we need only say they have electric fans for hot and electric radiators for cold weather, and as to the cuisine its excellence is well known, and accounts in part for the eagerness that people in the ports abroad manifest in the P. & O. ships.

Accommodation of the Crew.

As to the accommodation of the crew, which is what interests the readers of The Lancet, there can be about *Malwa* only a good report. The officers are berthed above the promenade deck, the white crew forward in the forecastle. These last are all petty officers, and live in cabins with two, three, or six beds. The beds are spring beds with hair mattresses, and for each man there is a locker. I would have liked to see a shelf or two and some hooks for clothes instead of the nails there were, but bright brass knobs to some of the bed frames gave an unusual appearance of cheerfulness and comfort. The lavatories and baths (earthenware) were good and numerous, salt water the only supply to baths, here as throughout the ship, but fresh water for the lavatory basins. No ship with so many passengers could carry fresh water enough for full length baths in the tropics for even a fortnight's run, let alone for four weeks. Forward also are berthed the Goanese stewards, in a sleeping deck with double-tiered cots, and I should say 120 cubic feet per person. Hot it would be, every place in a ship in the tropics is hot, but I was very glad to see that the ten windows, ports, or scuttles were fitted with Utley's patent ventilating sidelights, which allow air to come in, though they keep water out absolutely[1] and are consequently of the greatest use in the monsoon weather, when seas are rough and ordinary ventilators are closed. They cost twice as much as the ordinary sidelights and are twice the weight, but they are a great comfort to those who live near them in bad weather, and one cannot but feel obliged to the company which has had them fitted in a crew space, evidencing its consideration for its employees. Nobody who is unacquainted with the poisonous atmosphere which develops in a crowded crew space in warm, heavy—i.e., bad—weather in the tropics can imagine the comfort it is to have "the fug" diluted with even a trickle of fresh air from the outside. I was told here, as usual, that these Utley sidelights never go wrong. These 61 Goanese stewards have about a dozen wash-basins, white earthenware, small square troughs, useful also for washing clothes, with fresh water taps over them; their baths were as already described, and their water-closets were good, pedestal closets, with lifting seats that could be, and had been, scrubbed; all were clean—the ship was to sail next day—and they were separated from one another by light wooden partitions. In each of the cells thus formed was a box for latrine paper; two boxes were deficient, and there was no paper in any of them, but at present the ship was in dock and the water-closets were officially not in use. All these w.-c. compartments were painted white throughout, and in all were a couple of sidelights to four closets. Quite good this installation, and better than that found in the ocean giants.

Next comes the accommodation for the first-class passengers already touched on, and further aft, the second-class saloon, smoking-room, music-room, &c., and further aft again, separated on every deck by a bulkhead (i.e., a partition), is the accommodation for the native crew, better than any I have hitherto travelled with, but I have never travelled in so large a ship with a native crew. Being aft they are deeper down in the ship, but that has advantages. They were stated to have, each of them, 140 cubic feet of space, but I was not, I think, assured that that figure was the result of exact measurement, with deduction of encumbrances. The space they had was any way larger than would probably have been given to invalid soldiers in a hospital carrier, and was arranged in double-tiered iron berths, the fittings used being very similar to those used in hospital ships. There was cork paint on the iron overhead and on the frames and webs, but not on the iron plates of the ship's side, which besides were not wood cased; still the iron berths did not touch the ship's side, and no bed could be wetted by the water running off the side when the iron sweated in cold weather. There are ventilators of supply and exhaust to cowls on the decks above—there is no artificial ventilation; in cold weather temperature is raised by small coal stoves. This ship is ten years old, and steam heating is installed in the newer ships built during and after the war. There are, I am told, washing places for the lascars, and I did see a latrine for them, but the plans for latrines for natives that were on board *Achilles*[2]—cement gutters on the deck which could be flushed from a tap—were to be preferred. At the after end of the lascars' deck is a railed-off section for sick lascars taking passage as invalids—lying-down cases, but not infectious. Now this is a great comfort.

Medical Arrangements.

As regards the medical arrangements of the ship, there is on the boat deck, over the promenade deck and not accessible to any passenger, an infectious hospital, which, considering it has to deal with such cases for a population of 750 only, would appear to be quite sufficient. Two four-berth cabins, one to starboard, one to port, one for men, one for women, each with bath, washing-basin, water-closet, steam radiator, fan, and portholes. Alongside is a cabin for an attendant. This is a very satisfactory installation. The crew will also be isolated up here, but natives with their own straw mattresses and bedding, Europeans with the usual cabin equipment. In the newer and larger ships this boat deck extends over the whole of the ship to the stern, and the infectious hospital is moved to the after end, a plan which has much to recommend it, and to which I see no objection. The medical staff is a surgeon, with him a steward he has trained, and in future another steward is to be added for the infectious hospital. (Naval medical officers will be glad to know I heard something about a pensioned naval sick-berth steward being possibly the first.) The surgeon is placed at the starboard after corner of the first-class passengers' accommodation, where he is readily accessible to first- and second-class passengers and to the crew. He has here a hospital of two two-bed wards, with, for each, the usual annexes. The dispensary, large, well lighted, and well supplied, is between his cabin and the hospital. Here is an operating table, which can be rapidly set up and securely fastened to the floor; a sufficient stock of instruments is supplied by the company, and in this ship was a most useful piece of equipment, a carrying chair—a great help to the surgeon, for many sick people take passage in the P. & O. from year to year (there are more deaths amongst the passengers than amongst the sailors of the line)—and one can always extemporise a carrying chair, but the results of prevision are habitually superior. Next door to the dispensary, and communicating with it, is the surgeon's commodious cabin. It is his duty to examine the crew when they join (assisted by the dock surgeon of the company, as it were a D.A.D.M.S.), he sees the sick; and he has to know what is happening, and to answer the many questions propounded to him by the various port medical officers who come on board. Also I found, when a ship's medical officer, I was a buffer state between the captain and troublesome lady passengers. The post is responsible, and at times of epidemics anxious, but in a P. & O. mail steamer, what with the variety of the ports visited, the moderate weather of the region in which they sail, the society of the officers and passengers, and the table the company spreads, it is an employment with many compensations, and at present extremely popular. Employment under the P. & O. is for the officers continuous, for the surgeon pretty much the same, while the crew sign on for each trip separately, but are really employed continuously so long as they do not get themselves disliked or invalided, and I should say that any seaman might be pleased to go to sea in the *Malwa*.

Morbidity and Mortality on Board Ship.

I was taken over this ship by the experienced medical superintendent, and I have voyaged in others of this line; those ships were smaller, this was larger and better, and I hear of better existing beyond. The management seems to me to be more sympathetic than formerly, more anxious to give its servants better conditions than it was 20 years ago, and it gives them in this ship accommodation that is quite up to and indeed ahead of that customary in the merchant service of to-day. It would be absurd to ask the company to make alterations here and now, when losses on passenger voyages are being counted in tens of thousands of pounds, and giant liners are being laid up, and they tell me down the Commercial-road that if 20 men are wanted for a ship the shipping office is swamped by 200 eager applicants. Most men would rather take a chance of death by phthisis in five years than a large probability of death by starvation in five weeks. Better to have a slightly imperfect ship running than no ship at all and 400 sailors more out of work. Yet there is advantage in considering these questions and discussing any "leading" that may seem to emerge.

---

[1] THE LANCET, 1902, i., 1597.

[2] THE LANCET, 1920, ii., 1110.

Recent statistics of illness and deaths of sailors in the Eastern trade were brought by *Dr. Arnold Chaplin* before the Epidemiological Section of the Royal Society of Medicine in February.[3]

The figures are shown in the table which follows.

Comparative Illness and Death-rates of Sailors in the Eastern Trade: (A) Lascars; (B) Europeans.	(A)	(B)	(A)	(B)
	Per 1000.		Relative proportions.	
General death-rate, 1912	5·4	3·5	154	100
In 16 years in the Eastern trade, general death-rate	4·2	2·6	161	100
Pneumonia, mortality..	0·8	0·3	266	100
Phthisis, attack-rate	5·0	2·0	250	100
,, mortality	0·17	0·14	335	100

That is, natives have a liability to disease in the Eastern trade 61 per cent. greater than that of Europeans; to death from pneumonia. 166 per cent. greater; to attack by phthisis, 150 per cent. greater, and to death from phthisis, 235 per cent. greater than that of white sailors in the same ships. Probably the white sailors are older, and we have no account of the relative ages, or of the age-distribution of the illnesses. Of course it may be easily asserted that the difference is due to a congenital lesser resistance of the natives to disease. Such an explanation rises easily to the lips, and is difficult of disproof. Not otherwise, 30 years ago, did people ascribe to climate diseases since learned to be attributable to mosquitoes, trypanosomes, or ankylostoma. Not otherwise, in the older days, were cases of typhoid fever being described in service reports as "due to *infection on leave*," yet were, I noticed, becoming steadily fewer and fewer, as more careful attention was being paid to men's life when on duty. Take phthisis, 5 per 1000 natives were attacked, but only 2 per 1000 Europeans. Let it be noticed that the European crews have better ventilated quarters, and with more *isolation*. There are some 100 lascar firemen in this unusually well-ventilated ship, in a single compartment, with 140 cubic feet of space to each, good beds, and four large (let us say 18 inches diameter) ventilating shafts and many portholes. A case of phthisis introduced has a great opportunity to spread, though *lessened* by the quite tolerable ventilation. Still the bacilli have a chance to find a suitable nidus among the 20 men around, but in a white man's cabin forward, with two, three, or six beds, the chances in its favour would be fewer, the better ventilation of cabins higher up in the ship being always remembered as well.

Further Development in Ventilation.

This company has made great advances, but *Plus ultra* is a motto that cannot be unknown to those who sail through the Pillars of Hercules and handle Mexican dollars. Clearly a ship is coming in which ventilation is given thorough examination. What strikes one so much is the little use that is made of the "wild heat" from the boilers and engine-rooms. That is a waste product, and like so many others in industry is being thrown away. It should be used *to ventilate all the central part of the ship*; but look how tiny are the openings generally found on the boat deck. Old men-of-war were ventilated into the funnel casing—there is no funnel casing nowadays. But the ends of the ship must have artificial ventilation, and this should have been in mind from the time the first sketches of the ship were made. Artificial supply, artificial exhaust, as in *Olympic*, the best ventilated ship I have seen, with one funnel exclusively a ventilation exhaust. Ventilation is the great problem of healthy life in ships. It will reduce the cubic space necessary for the men, at the same time making them more comfortable; it will thereby release to the owners more space to be income-earning. The great advances at sea these 30 years are iron ships, without leaks, replacing wood, and *electric light replacing* candles and lamps. Electric light means that steam is always up, and so ventilation can always be maintained; that will get better work out of the crew, and it can be applied to holds when cargo is being worked; that will mean quicker stowage, and quicker despatch for the ships. Also there must *be an engineer told off* to watch the ventilation, to keep it running properly, to write up a log, and make reports which will show the captains that the companies think that ventilation is important. Then it will be always satisfactory. It is a thousand pities that the Naval Medical Department, with its vast experience, *does not put out a book* on the ventilation of ships to be a guide to all ship constructors and managers, and to improve the health of passengers and crews of our island nation. It might well copy the publicationary zeal of the sister service.

Meanwhile, as regards *the P. & O. Company*, it is clear that the owners are showing themselves considerate, that their newer ships are well arranged, that their newest are better still, and that in future, when others are built, they will surely maintain their standard, a high standard as one is glad to witness.

BRITISH MEDICAL ASSOCIATION:
ANNUAL MEETING.

THE eighty-ninth annual meeting of the British Medical Association will be held at Newcastle-on-Tyne, where the sixty-first annual gathering met in 1893. On Friday, July 15th, the Annual Representative Meeting will open at 10 A.M., and be continued on the following days. Other arrangements are as follows: Friday, July 15th, at 7.30 P.M., Representatives' Dinner; Tuesday, July 19th, 2 P.M., Annual General Meeting; 5 P.M., Religious Services; 8 P.M., Address by the President, Prof. DAVID DRUMMOND, and Adjourned General Meeting; Wednesday, July 20th, 2 P.M., Conference of Secretaries; 6.30 P.M., Secretaries' Dinner; 8 P.M., Special Address on Industrial Medicine by Sir THOMAS OLIVER; Thursday, July 21st, 7.30 P.M., Annual Dinner of the Association; Friday, July 22nd, 7.30 P.M., Popular Lecture on "Evolutionary Wounds," by Sir ARTHUR KEITH. The 17 sections will conduct their discussions on one, two, or all of the following days: Wednesday, Thursday, and Friday, July 20th, 21st, and 22nd. The sections will meet from 10 A.M. to 1 P.M.; laboratory and clinical demonstrations will be given between 3 P.M. and 4.30 P.M.

Section of Medicine.

President: Prof. Thomas Beattie; Vice-Presidents: Lord Dawson of Penn, Prof. A. J. Hall, Dr. G. S. Haynes, Dr. J. Wilkie Smith; Hon. Secretaries: Dr. C. E. Lakin (105, Harley-street, London, W. 1); Dr. W. T. Ritchie (11, Rothesay-place, Edinburgh); Prof. W. E. Hume (1, Ellison-place, Newcastle-on-Tyne).

Provisional Programme.—July 20th, 10 A.M.—Discussion: Visceral Syphilis, especially of the Central Nervous System and Cardio-Vascular System: to be introduced by Sir Clifford Allbutt. July 21st, 10 A.M.—Discussion: Asthma and Allied Disorders: to be opened by Sir Humphry Rolleston. July 22nd, 10 to 11.30 A.M.—Discussion: Encephalitis Lethargica: to be opened by Dr. Edwin Bramwell; 11.30 A.M. to 1 P.M.—Discussion: Renal Efficiency Tests: to be opened by Prof. H. Maclean.

---

[3] THE LANCET, March 19th, 1921.

Section of Surgery.

President: Prof. J. Rutherford Morison; Vice-Presidents: Prof. H. Brunton Angus, Mr. Arthur Cooke, Mr. W. J. Greer, Dr. A. M. Martin; Hon. Secretaries: Mr. W. Girling Ball (77, Wimpole-street, London, W. 1); Mr. J. M. Renton (16, Sandyford-place, Glasgow, W.); Mr. G. Grey Turner (The Hawthorns, Osborne-road, Newcastle-on-Tyne).

Provisional Programme.—July 20th, Morning Session.—Discussion: Acute Pleural Empyema: to be opened by Mr. Henry Wade. At 3 P.M., demonstrations by Prof. Rutherford Morison at the War Pensions Hospital of cases and specimens illustrating (1) Bipp, (2) Bone Cavities, (3) Bone Grafts. July 21st, Morning Session.—Discussion: Compound Fracture of the Thigh and Leg. At 3 P.M., demonstrations at the Royal Victoria Infirmary of cases and specimens, illustrating Compound Fracture of the Thigh and Leg. July 22nd, Morning Session.—Discussion: The Diagnosis and Treatment of Injuries of the Intestines: to be opened by Mr. Gordon Taylor. At 3 P.M., demonstrations by Mr. G. Grey Turner at the Royal Victoria Infirmary of six cases of implantation of the ureter into the bowel.

Section of Pathology and Bacteriology.

President: Prof. Stuart McDonald; Vice-Presidents: Dr. J. F. Gaskell, Dr. James A. Murray, Prof. Matthew J. Stewart; Hon. Secretaries: Dr. R. R. Elworthy (West London Hospital, Hammersmith, London, W. 6); Dr. A. F. Bernard Shaw (Pathological Department, College of Medicine, Newcastle-on-Tyne).

Pathological Museum.—It is proposed to gather together a series of exhibits illustrating the pathology of individual cases. The Pathological Museum Committee will arrange the material under the following heads: (1) Exhibits bearing on discussions and papers to the various sections; (2) specimens and illustrations relating to any recent research work; (3) instruments relating to clinical diagnosis and pathological investigation; (4) individual specimens of special interest or a series illustrating some special subject. Interesting specimens will be welcomed. The Hon. Secretary of the Committee is Dr. A. F. Bernard Shaw.

Section of Preventive Medicine with Industrial Diseases.

President: Sir Thomas Oliver; Vice-Presidents: Sir Josiah Court, Dr. T. Eustace Hill, Dr. I. G. Modlin; Hon. Secretaries: Dr. C. M. Wilson (64, South Audley-street, Grosvenor-square, London, W. 1); Dr. W. H. Dickinson (1, Ridley Villas, Newcastle-on-Tyne).

Provisional Programme.—July 20th.—Discussion: The Effect of Health Legislation on the Health of the People. July 21st.—Discussion: The Importance of Industrial Medicine to the Community: to be introduced by Prof. E. L. Collis, followed by Dr. T. M. Legge. July 22nd.—Joint meeting with the Section of Medical Sociology.

Section of Orthopædics and Diseases in Children.

President: Mr. A. H. Tubby; Vice-Presidents: Mr. R. C. Elmslie, Dr. H. Morley Fletcher, Dr. Lachlan G. Fraser, Sir Henry M. W. Gray, Mr. A. E. Morison; Hon. Secretaries: Mr. C. Max Page (134, Harley-street, London, W. 1); Dr. Frank Hawthorn (10, Ellison-place, Newcastle-on-Tyne); Dr. H. R. Souper (Ministry of Pensions Hospital, Castle Leazes, Newcastle-on-Tyne).

Preliminary Programme.—July 20th, 10 A.M.—Discussion: The Early Diagnosis and Treatment of Anterior Poliomyelitis. July 21st, 10 A.M.—Discussion: Blood Diseases in Children. July 22nd, 10 A.M.—Discussion: Tuberculosis of Bone: General Principles of Treatment.

Section of Neurology and Psychiatry.

President: Prof. A. W. Mackintosh; Vice-Presidents: Dr. A. Helen A. Boyle, Dr. E. Farquhar Buzzard, Dr. Harry Campbell, Dr. Horsley Drummond; Hon. Secretaries: Dr. Anthony Feiling (41, Devonshire-street, London, W.); Dr. George Hall (1, Eslington-road, Jesmond-road, Newcastle-on-Tyne).

Provisional Programme.—July 20th, 10 A.M.—Discussion: The Diagnosis and Treatment of Borderland Cases: to be opened by Prof. G. M. Robertson and Dr. James G. Collier. July 21st, 10 A.M.—Papers.

Section of Ophthalmology.

President: Prof. J. D. Wardale; Vice-Presidents: Dr. H. P. Bennett, Lieut.-Col. R. H. Elliot, Dr. Harry M. Traquair; Hon. Secretaries: Dr. N. B. B. Fleming (9, Harley-street, London, W. 1); Mr. Stanley Robson (Milton-house, Rowlands Gill, Co. Durham).

Provisional Programme.—July 20th, 10 A.M.—Discussion: The Causes and Prevention of Blindness: to be opened by Mr. Bishop Harman. July 21st, 10 A.M.—Discussion: The Treatment of Corneal Ulcers: to be opened by Mr. J. V. Paterson.

Section of Oto-Rhino-Laryngology.

President: Dr. G. William Hill; Vice-Presidents: Dr. R. Gordon Bell, Dr. James Don, Dr. Dan Mackenzie; Hon. Secretaries: Mr. Lionel Colledge (22, Queen Anne-street, London, W. 1); Dr. W. Frank Wilson (97, Jesmond-road, Newcastle-on-Tyne).

Provisional Programme.—July 20th, 10 A.M.—Discussion: Problems in connexion with the Early Diagnosis and Treatment of Meningitis occurring in Aural Cases: to be opened by Sir Charles Ballance. July 21st, 10 A.M.—Discussion: The Various Problems presented by Hæmorrhage occurring in connexion with Operations on the Tonsils.

Section of Physiology, Pharmacology, Therapeutics, and Dietetics.

President: Dr. H. H. Dale; Vice-Presidents: Prof. A. V. Hill, Prof. John C. Meakins, Prof. J. A. Menzies, Dr. Alfred Parkin; Hon. Secretaries: Dr. O. Inchley (Babraham, Cambridge); Miss Mildred Atkinson (College of Medicine, Newcastle-on-Tyne).

Provisional Programme.—July 20th.—Paper by Prof. Hill: The Use of the Hot Wire for Investigating (*a*) the Time Relations of the Pulse; (*b*) the Characteristics of Voluntary Contractions in Man. Paper and demonstration by Prof. J. A. Menzies, Miss Atkinson, and G. A. Clark: The Passage of Sulphate through the Cells of the Tubules of the Kidney of the Frog. Paper by Dr. Dale: Anaphylatoxin. July 21st.—Paper, with lantern demonstration, by Dr. H. Muir Evans: The Poison Organs and Venoms of Venomous Fish. Paper by Prof. C. H. Browning: Recent Work on Chemotherapy. Paper by Dr. G. Arbour Stephens: Acid Feeders. Paper by Dr. Sim Wallace: Physiology of Oral Hygiene. July 22nd.—Joint discussion with the Section of Medicine on Tests for Renal Efficiency.

Section of Venereal Diseases.

President: Col. L. W. Harrison; Vice-Presidents: Dr. James Charles Buckley, Mr. Charles Gibbs, Dr. Mary Raw; Hon. Secretaries: Mr. Kenneth M. Walker (86, Harley-street, London, W.); Dr. James Hudson (42, Crossley-terrace, Newcastle-on-Tyne).

Provisional Programme.—July 20th, 10 A.M.—Treatment of Syphilis in Man, by Dr. R. MacKenna; Syphilis in Women and Children, by Prof. Walter Swayne. July 21st, 10 A.M.—Treatment of Gonorrhœa in Men, by Dr. David Lees; The Standard of Cure in Gonorrhœa, by Mr. Townley Clarkson. In the afternoon of Wednesday, July 20th, a demonstration will be held of Methods of Diagnosis and Treatment in Venereal Diseases, Dark-Ground Illumination Work, Models of Venereal Disease Clinics, &c.

Section of Obstetrics and Gynæcology.

President: Prof. R. P. Ranken Lyle; Vice-Presidents: Lady Barrett, Dr. W. R. Grove, Mr. William Robinson; Hon. Secretaries: Mr. Gordon Ley (5, Wimpole-street, London, W. 1); Dr. Mabel R. Campbell (49, Wingrove-road, Newcastle-on-Tyne); Dr. E. Farquhar Murray (52, Jesmond-road, Newcastle-on-Tyne).

Provisional Programme.—July 21st, 10 A.M.—Discussion: The Rôle of Cæsarean Section in Midwifery: to be opened by Dr. Eardley L. Holland and Dr. J. M. Munro Kerr. Paper: The Treatment of Advanced Malignant Disease of the Cervix, by Dr. Arthur Burrows, to be followed by a discussion. July 22nd, 10 A.M.—Discussion: The Neurasthenic Element in Midwifery and Gynæcology: to be opened by Dr. Archibald Donald and Dr. Farquhar Buzzard. Papers to be followed by discussion: (1) Curettage, (*a*) Diagnostic, (*b*) Treatment of Uterine Hæmorrhage, by Mr. H. Beckwith Whitehouse; (2) The Position of the Medical Practitioner called in to attend a case of Procured Abortion, by Dr. John Campbell.

Ambulance and Red Cross Section.

President: Sir James Cantlie; Vice-Presidents: Dr. Robert Anderson, Sir G. T. Beatson, Major-General Sir G. J. H. Evatt, Rev. C. F. Townley; Hon. Secretaries: Lieut.-Col. R. M. Vick (The Warden's House, St. Bartholomew's Hospital, London, E.C. 1); Dr. H. L. Rutter (31, West-parade, Newcastle-on-Tyne).

Section of Proctology.

President: Mr. J. P. Lockhart-Mummery; Vice-Presidents: Dr. Henry B. Densham, Mr. Ernest Miles, Mr. D. P. D. Wilkie; Hon. Secretaries: Mr. Cecil W. Rowntree (9, Upper Brook-street, London, W. 1); Mr. Hamilton Drummond (6, Saville-place, Newcastle-on-Tyne.)

Provisional Programme.—July 20th.—Discussion: Surgical Treatment of Internal Hæmorrhoids, to be opened by Sir C. Gordon Watson and Mr. D. P. Wilkie.

Section of Dermatology.

President: Dr. John Farquhar Christie; Vice-Presidents: Dr. Ernest Dore, Dr. Arthur D. Heath, Dr. D. Wells Patterson; Hon. Secretaries: Dr. William Jenkins Oliver (58, Queen Anne-street, London, W. 1); Dr. Sydney Thompson (19, Windsor-terrace, Newcastle-on-Tyne).

Provisional Programme.—July 21st, 10 A.M.—Discussions: (1) Cutaneous Sensitisation and Focal Sepsis in the Ætiology of Certain Skin Affections: to be opened by Dr. H. W. Barber; (2) The Association of Skin Tuberculosis with Visceral and other Tuberculous Manifestations: to be opened by Dr. George H. Lancashire; (3) Dermatological Cases attending the Pensions Boards: to be opened by Dr. Henry MacCormac.

Section of Medical Sociology.

President: Sir Jenner Verrall; Vice-Presidents: Dr. Charles Buttar, Dr. A. C. Farquharson, Dr. E. Rowland Fothergill; Hon. Secretaries: Dr. J. F. Walker (Rocklands, Clifton-terrace, Southend-on-Sea); Dr. Mabel G. Brodie (Maternity and Child Welfare Offices, 42, Old Elvet, Durham).

Provisional Programme.—July 22nd, 10 A.M.—Discussion: Relation of the Medical Profession to Local Authorities in respect to Rate-provided Hospitals and Clinics.

Section of Radiology and Electro-Therapeutics.

President: Dr. Robert Knox; Vice-Presidents: Mr. W. Hope Fowler, Dr. Robert Edward Howell; Hon. Secretaries: Dr. James Metcalfe (123, Harley-street, London, W. 1); Dr. Thomas Lowe Bunting (6, Portland-terrace, Newcastle-on-Tyne).

Provisional Programme.—July 22nd, 10 A.M.—Discussion: On the Changes induced in Blood Constituents by Radiations: (*a*) Experimental Evidence, Prof. Sidney Russ and Dr. Archibald Leitch; (*b*) Clinical observations, Dr. Mottram, Dr. Gamlen, Dr. J. B. Waters, Dr. Metcalfe, Dr. Hope Fowler, and others. On Morbid Conditions of the Blood: (1) The Anæmias, (2) Leukæmia, (3) Banti's Disease, &c. Opening paper by Prof. G. L. Gulland. Discussion on Surgical Diathermy, to be opened by Dr. Cumberbatch. A visit will be paid to the X ray and electrotherapeutic department of the Royal Victoria Infirmary, Newcastle-on-Tyne.

Section of Urology.

President: Mr. J. W. Thomson Walker; Vice-Presidents: Dr. P. J. Cammidge, Mr. John Clay, Mr. H. C. Pearson; Hon. Secretaries: Mr. Sydney G. MacDonald (51, Queen Anne-street, London, W. 1); Mr. W. S. Dickie (Ardencapel, Southfield-road, Middlesbrough).

Provisional Programme.—July 22nd, 10 A.M.—Discussion: The Diagnosis and Treatment of Cystitis: to be opened by Mr. J. F. Dobson. Papers: Experimental Evidence Bearing on the Source of the Amylolytic Ferment in the Urine, by Dr. P. J. Cammidge; Open Prostatectomy, by Mr. J. W. Thomson Walker; Treatment of Bladder Growths, by Mr. Sydney G. MacDonald.

The Honorary Local General Secretary of the meeting is Mr. R. J. Willan, M.V.O., O.B.E., F.R.C.S., 6, Kensington-terrace, Newcastle-on-Tyne.

THE WELSH NATIONAL SCHOOL OF MEDICINE.

MEDICAL interest attaches to the installation of the Prince of Wales as Chancellor of the University of Wales in succession to his father. The laying of the foundation-stone of the new Institute of Preventive Medicine, and the formal opening of the physiological buildings, recalls the fact that both these buildings owe their existence to the same generous benefactor, Sir W. J. Thomas. The new institute should be unique in the medical schools of this country. It is to house the public health laboratories of Glamorgan and the City of Cardiff, and provide accommodation for teaching and research for the Mansel Talbot Professor of Preventive Medicine, Dr. E. L. Collis, whose chair was endowed a few years ago by the late Miss Talbot. The establishment of this department also owes much to the interest taken in it by the late Sir William Osler and to the advice he gave; he saw a great opportunity for the development of preventive medicine in connexion with the Welsh National School of Medicine. This medical school at this moment is at an interesting stage. For some 30 years the school has been in existence at Cardiff, but hitherto has not carried teaching beyond the anatomy and physiology stage; its students have gone elsewhere to obtain clinical teaching. Completion of the full curriculum has long been under contemplation and was recommended by the Royal Commission on Welsh University education, of which Lord Haldane was the chairman. This Commission held that the medical school should be an independent College in the University, but the claims of the University College of South Wales and Monmouthshire, which fostered the school through its initial stages, to remain suzerain, have prevailed. The school is to be governed by a Board of Medicine and a Faculty of Medicine, having the status of a Senate. Additional grants arising from a penny rate levied by the local authorities of Wales, and met by an equal sum from the Treasury, are providing the initial funds. The school is planned on the unit system; a professor in pathology and bacteriology, whose department in laboratory accommodation and in teaching strength must now be enlarged, has been in existence for some years. Now whole-time professors of medicine and surgery are to be appointed immediately, so that a full course can be embarked upon next October.

Clinical Work.

The clinical work is to be established at the King Edward VII. Hospital at Cardiff. At first the beds at the disposal of the clinical professors will be below the desired number; but when hospital finance is on a better footing the position will be remedied, while the possibility exists of obtaining immediate facilities at the Poor-law infirmary and at the Seamen's Hospital. The plan under consideration is not to extend the hospital on its present site, but to establish a large branch for convalescent and less important cases a few miles outside the city. Action on these lines would be at once less expensive than extension within the city, and would place the patients under more ideal climatic surroundings. At the same time an effort is to be made to concentrate at the central hospital all forms of out-patient clinical work—*i.e.*, tuberculosis, venereal, infant welfare, and school work—in addition to psychiatry and ordinary out-patient work which already are carried on. Under the able direction of its new chairman, Sir William Diamond, extension and consolidation of the work of the hospital may be confidently anticipated.

The Cardiff district provides excellent material for the teaching of special subjects—at the City Sanatorium for infectious diseases, and at the Whitchurch Hospital for mental cases: while close association of the medical school with the King Edward VII. Welsh National Tuberculosis Association is assured through the newly-endowed David Davies Chair of Tuberculosis, the holder of which, Dr. S. Lyle Cummins, is also principal medical officer to the Association. The number of students is at present 250, spread over the first three years of study. Since, however, the figure contains certain ex-Service students, it is above the average to be expected in the future, but a steady entry year by year of between 50 and 60 students is anticipated. Much yet remains to be done to provide adequate facilities during the three clinical years for this number of students, and heavy responsibility must lie with the new Board of Medicine to obtain these facilities, and with the Faculty of Medicine to organise the teaching with the means at their disposal in accordance with modern thought. But the forging of a new school must of necessity be a difficult and toilsome procedure. To-day the metal of opinion in Wales is hot, and if constructive blows are shrewdly dealt, and if further benefactors to this national effort are forthcoming, a high grade medical school will be constructed of which the Principality may be justly proud.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THURSDAY, MAY 26TH.

THE Council proceeded to the consideration of various reports.

Report of the Public Health Committee.

The report was presented by Sir JOHN MOORE (chairman of the Public Health Committee). The Committee has considered the returns (*a*) of professional examinations held in 1920 for Diplomas in Public Health, and (*b*) of exemptions granted by the licensing bodies from any of the rules of the Council in regard to such diplomas. The salient facts are summarised as follows: During 1920, 453 candidates were examined for the first examination, of whom 342, or 75·5 per cent., passed, and 111, or 21·5 per cent., were rejected. For the second and final examination 463 candidates presented themselves, of whom 373, or 80·6 per cent., were successful, and 90, or 19·4 per cent., failed. During the year the English Conjoint Board granted exemptions to 7 out of 142 candidates; the University of Liverpool granted exemptions to 8 out of 33 candidates; and the Victoria University of Manchester granted an exemption to 1 out of 43 candidates. Seventeen bodies granted no exemptions during the year in regard to qualifications in Public Health.

Since its last report the Committee has received reports, together with the remarks of the bodies concerned, from the Universities of London, Birmingham, Leeds, Sheffield, Edinburgh, and Glasgow. All the bodies whose examinations have been inspected have sent in their remarks, except the University of Durham and the Scottish Conjoint Board. The only bodies remaining to be inspected are the Universities of St. Andrews, Dublin, the Queen's University of Belfast, and the Irish Conjoint Board.

During the recess the chairman had dealt with a number of applications for special consideration, and the Committee at its meeting had considered and approved the action of the chairman in each case.

After presentation of the report Sir John Moore read the following recommendation of the Public Health Committee:—

That in view of the fact that the Committee has reason to expect the completion of the inspection of Public Health Examinations in July, and with a view to preparing a detailed report on these inspections, and on the proposed revision of the resolutions and rules for diplomas in Public Health, the Committee recommend that the Council should sanction a special meeting of the Public Health Committee for these purposes to be held in the last week in September.

The report of the Public Health Committee, together with the above recommendation, were adopted by the Council.

Report of Students' Registration Committee.

The Council considered the report of the Students' Registration Committee, which included notice of the registration antedated according to precedent, of 101 medical students and 27 dental students, together with details and treatment of applications for registration and antedating in exceptional circumstances. The report also contained the Committee's resolution to the effect that application having been received for the approval of the Council of the Central Secondary School, Sheffield, and the Handsworth Technical School, Birmingham—both of which are recognised by the English Conjoint Board—these institutions be added to the list of those recognised by a licensing body and approved by the Council.

The report of the Student's Registration Committee was adopted by the Council.

Report of the Pharmacopœia Committee.

The Council considered the report of the Pharmacopœia Committee, which was presented by the PRESIDENT (chairman of the Committee).

The report stated that the number of copies of the British Pharmacopœia, 1914, which were sold by the publishers between Nov. 20th, 1920, and May 21st, 1921, was 980. The number sold in the year ending May 21st, 1921, was therefore 3106. The total number sold since the date of publication is 39,958. The stock in hand is sufficient to meet the present demand for some time to come.

Numerous communications have been made on behalf of the Committee to the Home Office concerning the draft regulations under the Dangerous Drugs Act. The Secretary of State, finding that many well-founded objections were taken to certain of the proposed regulations affecting the prescribing and dispensing of potent remedies, agreed to set up a special committee to consider these. Evidence was furnished by the Pharmacopœia Committee, and by other medical and pharmaceutical bodies, in favour of a modification of the regulations, in such wise that, while ensuring public safety, they should not unduly fetter the legitimate distribution and use of the remedies in question. The revised regulations have been published in the *London Gazette* of May 24th, 1921, and they appear to give effect to the representations made by the Committee in the public interest.

The report of the Ministry of Health Committee on the "biological" control of certain therapeutic substances, which cannot be sufficiently tested by direct chemical means, has now been presented to Parliament.

The recommendations of the Committee are in general accord with those submitted on behalf of the Council in 1909. They propose the establishment of a Privy Council Committee as controlling authority; the appointment of an Advisory Committee, on which the General Medical Council should be represented; the provision of a Central Laboratory under the Medical Research Council; and the institution of a system of licensing, inspection, and testing of samples, which would ensure to the public that the therapeutic serums and other preparations offered for sale were of the prescribed standard quality. These proposals require legislation before they can become operative. Should they pass into law, certain changes in and additions to the text of the Pharmacopœia will become necessary. There will be no difficulty in effecting such alterations, and the Committee will be ready at the proper time to make suitable submissions to the Council on the subject.

A short discussion of the report followed, during which Mr. E. B. TURNER (a member of the Council of the British Medical Association) stated that there had been many inquiries addressed to him by members of the medical profession as to whether the General Medical Council had approved the original regulations; It was necessary to remove misapprehension on this subject. A certain number of regulations had been approved, but the Committee had objected to others, and care was taken that the objections reached the right quarter.

The PRESIDENT said that the regulations which came to the Committee were draft regulations, and their observations had been sent before the draft was published. They were surprised to find that the draft regulations were published without amendment. Apparently the draft had been confused with the final form in which the regulations had appeared.

The report was adopted by the Council.

Report of the Dental Education and Examination Committee.

Sir JAMES HODSDON (chairman of the Committee) presented this report.

The report stated that the annual returns of professional examinations held in 1920 for qualification under the Dentists Act called for no comment. The Committee has had the dental curriculum under consideration from November, 1915, to November, 1917, and recommends that, in view of the proposed amendment of the Dentists Act, the question of requiring some preliminary instruction in biology for dental students and the consideration of the 1917 report on the dental curriculum be again postponed.

In November, 1920, the Council passed certain resolutions which are to come into operation on Jan. 1st, 1923, in regard to the registration of medical students. If any of these resolutions are to apply to dental students it is important, in the interests of those who propose entering the dental profession, that the recommendations adopted by the Council in 1898 should be modified during the present session.

The existing recommendations for the preliminary examination and registration of dental students are:—

(1) "That every dental student shall, at the commencement of his studentship, be registered in the manner and under the conditions prescribed for medical students." (2) "That no person shall be registered as a dental student who has not previously passed one of the preliminary examinations in general education recognised by the Council."

In the report of the Departmental Committee on the Dentists Act (February, 1919, pp. 41, 153) the following recommendation is made: "We think that it is essential that a student, in ordinary circumstances, should have passed a preliminary examination in general education which should be the same for dental students as for medical students." Further, it is stated (152): "We notice that dental students may commence their course of professional study on reaching the age of 16. We are of opinion that a boy or girl who completes a course of study at a secondary school up to the age of 18 would probably be in a better position to profit from a course of professional study than one of the age of 16." The Departmental Committee's report (151) also states that—"It is desirable that the course of study in chemistry and physics should form a portion of the normal school course. A pass in science, with credit in chemistry and physics in the first schools examination, in secondary schools inspected by the Board of Education, should be accepted as entitling a student to enter his professional examination in these subjects, a pass in chemistry and physics in the second schools examination should be accepted as an adequate substitute for the professional examination in these subjects."

The recommendations of the Departmental Committee on the Dentists Act are thus similar to the "resolutions of the General Medical Council in regard to professional education" adopted by the Council in November, 1920.

The Dental Education and Examination Committee recommends that the preliminary examination and registration required of candidates for licences in dentistry or dental surgery be the same for dental students as for medical students, and that the recommendations adopted by the General Medical Council in May, 1898, be modified so as to provide:—

I. (*a*) That before registration in the Dental Students' Register every applicant shall be required to have passed, in addition to the examination in general education, an examination in elementary physics and elementary chemistry conducted or recognised by one of the licensing bodies.

(*b*) That before registration as a dental student every candidate shall produce evidence that he has attained the age of 17 years. Provided: "That the minimum standard of general education required by the Council for registration as a dental student should be raised to a standard equivalent to that demanded in other learned professions previously to, or concurrently with, the coming into operation of the requirements of a preliminary examination in science before registration."

II. That the requirements contained in recommendation I. come into operation on Jan. 1st, 1923.

British Dental Association and a Diploma in Public Dentistry.

The Executive Committee, at its meeting in February, referred to the Committee, for its information, a memorandum in regard to this matter. The Committee recommends that no action be taken with regard to this matter at the present stage.

R.C.S. England—Regulations for the L.D.S.—A copy of the new regulations has been received. The grouping of the subjects of the examination has been altered; general and dental anatomy and physiology have been separated from the examinations in general and dental surgery and pathology of the general professional examination, and now form Part III. of the final professional examination or the licence. Candidates who have passed the preliminary science examination may enter for the examination in general and dental anatomy and physiology after completing six months' study at a recognised medical or dental school.

The report concluded with detailed accounts of applications for colonial and foreign registrations and recommendations of the Committee upon them.

The report was adopted by the Council.

Appointment of General Registrar.

The proposal to reappoint Mr. Norman C. King as General Registrar was unanimously carried by acclamation.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Scarcity of Nurses in Hospitals.

As a consequence of the social upheaval, occupations requiring a more than ordinary amount of devotion are not much sought after by the lower classes of the population. If it is hardly possible at present for a middle-class household to find a servant, this fact, not in itself important from the standpoint of the State, assumes a different aspect when it is considered that numerous women unused to household work now have to do it, and thereby suffer severely in health. Moreover, the children cannot be looked after so thoroughly if the middle-class mother has to leave them to do shopping, &c. The general health is thus materially affected. Still more important is the fact that the very onerous vocation of nursing is now becoming discredited. In the General Hospital alone, where good pay and good board are available, more than 70 sisters are wanted. In this country before the war nurses were mostly recruited from the same class as servant girls, barmaids, and factory hands. Better educated girls only took up this calling during the war. The latter now find it easier to work in shops or offices, whilst hospital nurses are eager to go out to the country hospitals, where they are much better off, with less work. Owing to the 8-hour day, instituted by law even in hospitals, the numbers required are trebled, and the scarcity results both from the removal of qualified women from the city and the absence of new-comers, necessitating the closing of several wards in the General Hospital.

Difficulties of Teaching Anatomy.

A serious condition has arisen in our anatomical institutes with regard to the problem of dissection. Hitherto all unclaimed bodies of persons dying in the hospitals were brought to the anatomical dissecting rooms for didactic purposes, together with many corpses of suicides and stillborn children. But with the break-up of the old empire the once large number of unclaimed bodies of patients from distant parts fell to nearly nil; furthermore, a private charitable religious society has been formed which claims nearly every dead body and gives it burial with religious rites within three days after death. The present first-year students have not much opportunity for dissection and have to be satisfied with study of skeletons and preserved specimens at the anatomical museum; and now and then one group of students can watch another group dissect a corpse. Naturally, the authorities of the medical faculty are endeavouring to improve the state of things. Legislative measures are suggested to enable adequate teaching of the principles of anatomy to be continued.

The "Allotment" Movement in Vienna.

Food scarcity during the war resulted in cultivation of vegetables on every available plot of waste ground, even within the city, where numerous public gardens and squares were also converted for the purpose. This national necessity has now been so impressed upon the town-dwellers that the precincts and outskirts of Vienna at present form a zone of highly-cultivated small gardens and allotments. The citizens are fully aware of the enormous advantages to be derived from this kind of work, not only from the economic point of view, but also from the physical, mental, and moral standpoints. Only by these means can the town-dweller rid himself of dependence upon the agricultural profiteer. Fully 25 per cent. of the supply of potatoes, 18 per cent. of cabbages, tomatoes, beans, and other fresh vegetables required by the population of Vienna have been derived last year from this source; and the slowly but steadily improving health of the bulk of the population is undoubtedly due to work in the fresh air and physical exertion.

Legal Permission for Interruption of Pregnancy.

The National Assembly will shortly be called upon to decide whether a law should be passed permitting the interruption of pregnancy whenever stringent medical or economic reasons demand it. The interruption should take place before the fœtus is three months' old, and nobody but a doctor of medicine should be permitted to perform the operation, of which a report must in each case be made to the Board of Health. Grave social and economic conditions, especially amongst families with numerous children, make this demand easy to understand; it clearly emanates from a real feeling of responsibility on the part of the politicians who have drawn up the report, amongst whom are nearly all the female members of the National Assembly.

X Ray Treatment of Cancer of the Uterus.

At a recent meeting of the Medical Society of Vienna Professor Weibel read an instructive paper on treatment of cancer of the uterus by X rays. The lecturer pointed out that it is only nine years since the first case of such a treatment was reported, and the initial enthusiasm with which the use of radium was received soon disappeared, while X rays continued to be used alone. In Erlangen and Berlin especially this method was much employed, and in high doses; it was believed that by applying a certain amount of the rays it was possible to kill or devitalise the cancer cells. But the after-results are not too encouraging. The method of the Berlin school makes it necessary to give the patient a transfusion of about 1000 cubic centimetres of blood immediately after the X ray sitting because of the rapid weakening of the patient. The donor, preferably one of the patient's relatives, must be waiting for the procedure at the doctor's office. The results of the extensive investigations of the Vienna school in this line go to show that it is possible, by combining X ray and radium treatment, applied after a radical operation, to cure cancer of the womb in about 50 per cent. of all observed cases. Only 20 per cent. of all cases can be regarded as fit for treatment without operation—i.e., by radiotherapy only; every case of cancer fit for operation should be operated on without losing time by previous radiotherapy; the latter follows the operation. Maximal doses should be used wherever possible. Professor Weibel prefers the vaginal route instead of the abdominal route, and its mortality statistics appear better. As regards the apparatus, it does not matter much which outfit is used, as long as the required intensity is obtained. In fact, many of the excellent results obtained within the last two years are due to old plants, much used during war time. In the discussion which followed Professor Weibel's paper the majority of those present seconded the views explained in the paper, but some expressed their belief that in the near future the curative effects of radium would be more thoroughly understood.

May 28th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Remuneration of Practitioners Treating Pensioners.

ACCORDING to a French Parliamentary Act of March, 1919, the remuneration of practitioners treating ex-Service men in receipt of disability pensions is a State obligation, when they are consulted for sequelæ due to war wounds, or for disease contracted in or aggravated by service. It has been mentioned in this correspondence that when the Bill was passed it was decided that remuneration was to be settled by arbitration. On March 9th, 1921, a decree was published by order of the Minister of Pensions in the *Journal Officiel* standardising professional fees. But a great majority of general practitioners thought the decree of the Ministry of Pensions was not in accordance with the conclusions arrived at by a special committee which had been selected to report the matter. The Committee of the Union des Syndicats Médicaux de France have urged their members to oppose the decree ever since its publication. It was proposed to refer the decision to a committee consisting of delegates from the Ministry of Pensions, the Associations of Pensioners, and the Medical Syndicates. Since this suggestion was made the Minister of Pensions has invited members of all groups concerned to meet in conference. The Minister himself presided at the meeting. A compromise was reached, and it was decided that the decree will only be applied as far as previous medical attendances are concerned, while a new rate of remuneration will be adopted in the future to meet the practitioners' claims. It was also decided that there should be special rates of remuneration for surgical treatment and treatment given by specialists. These various rates of remuneration are to be settled by a committee consisting of delegates from the Ministry of Pensions, the Associations of Pensioners, the Union des Syndicats Médicaux de France, and this committee will also include medical practitioners who do not happen to be members of any syndicate.

Dangers of X Rays.

Since you have recently pointed out in your columns the scare promulgated by the Parisian popular press resulting from Mr. Contremoulin's report to the Academy of Sciences on experiments of his own, which indicate that it may be dangerous to live in the proximity of X ray centres, it may be of interest to your readers to know that at a recent meeting of the Académie des Sciences a special committee was appointed with the object of controlling Mr. Contremoulin's findings.

Radiology and the Medical Profession.

The Préfet de la Seine has recently selected a new chief of laboratory to be at the head of the X rays department of the Hospice de la Salpêtrière, where he is to occupy the post held previously by the late Mr. C. Infroit, whose death in the cause of science has been recorded in THE LANCET. This appointment has been officially accepted by Mr. P. Mourier, Directeur de l'Administration Générale de l'Assistance Publique. In consequence the Chairman of the Syndicat Général des Médecins Français Electrologistes et Radiologistes has addressed a letter to Mr. Mourier to let him know that the members of the Syndicate protest against his decision, on the ground that the newly appointed radiologist does not hold any medical qualification, and that such posts should be filled by medical men.

June 4th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Sir William Smyly and the Rotunda Hospital.

LAST week the Master of the Rotunda Hospital, Dr. G. FitzGibbon, and Dr. E. H. Tweedy, an ex-Master, presented to the hospital a portrait of Sir William Smyly, the senior surviving ex-Master. Sir William Smyly was Master from 1889 to 1896, and in making the presentation Dr. Tweedy referred to the great part which he had taken in modernising the work and equipment of the hospital, thus exercising an influence not only in Dublin, but throughout the kingdom. It was also largely due to Sir William Smyly's activity that the present gynæcological wing of the hospital was built, and it was during his mastership that efficient trained nursing was introduced.

Sir F. Conway Dwyer.

The name of Sir F. Conway Dwyer appears among the new knights in the list of birthday honours. Mr. Dwyer, who is one of the surgeons to the House of Industry Hospitals, was President of the Royal College of Surgeons in Ireland at the time of the outbreak of the war. For a considerable period he served as operating surgeon at King George V. Hospital with the rank of lieutenant-colonel. He is Inspector of Anatomy in Ireland.

An Honour for the Provost of Trinity College.

At their last meeting, the President and Fellows of the Royal College of Physicians elected as an Honorary Fellow the Right Honourable and Right Reverend J. H. Bernard, Provost of Trinity College.

Medical Representation in the Parliament of Northern Ireland.

The medical profession will be well represented in the Parliament of Northern Ireland. Of the four representatives of the Queen's University three are members of the medical profession—viz., Mr. John Campbell, Dr. R. J. Johnstone, and Dr. H. M. Morrison. Mr. Campbell is senior surgeon to the Samaritan Hospital, Belfast, and has long held a prominent position as a consulting and operating gynæcologist. He has been for some years Chairman of Convocation of the Queen's University Graduates' Association. He served in France as chief surgeon of No. 5 British Red Cross Hospital, and was adjutant and second in command of the Queen's University Veterans Volunteer Corps. Dr. Johnstone is professor [of gynæcology in the Queen's University of Belfast. He has been for twelve years a member of the Council of the British Medical Association, and has taken an active part in medical politics and administration. He is chairman of the Irish Medical Committee, and a former chairman of the Hospitals Committee of the British Medical Association. He is also a member of the Nursing Council for Ireland. He served during the war as one of the surgeons of the U.V.F. Hospital, Belfast. Dr. H. S. Morrison, who represents the country practitioners of the six counties, is coroner for the Coleraine District, and chairman of the South Londonderry Unionist Association and of the County Londonderry Branch of the Irish Union Alliance. The fourth member for the Queen's University, Mr. John H. Robb, a well-known member of the North-East Circuit, and the author of various legal text-books, has also close associations with the medical profession, to which his three brothers belong.

Ulster Medical Society.

At the annual meeting held in the Medical Institute, Belfast, on May 26th, the following officers were elected for the ensuing session:—President: Dr. Robert Hall. *Vice-Presidents*: Mr. James A. Craig, Belfast, and Dr. St. George, Lisburn. Council: Prof. C. G. Lowry, Mr. Howard Stevenson, Dr. W. Burns, Dr. V. G. L. Fielden, Dr. S. Boyd Campbell, Dr. M. Beath. Hon. Treasurer: Dr. S. I. Turkington. Hon. Secretary: Dr. W. W. D. Thomson. Hon. Librarian: Dr. W. L. Storey. Hon. Editorial Secretary: Dr. R. Marshall. A resolution of sympathy with Dr. W. W. D. Thomson in his prolonged illness was passed, and Dr. Marshall was thanked for his efficient discharge of his duties as secretary *pro tem.* A discussion took place on the finances of the society, and suggestions were made as to various means of meeting the annually recurring deficits in the budget.

SEAMEN'S NATIONAL INSURANCE SOCIETY.—The Society held its annual meeting in London on May 25th, Sir Norman Hill in the chair, when stock was taken of nine years' work. With the help of the medical profession a thoroughly efficient medical service has been established, available to every member in every port of the United Kingdom; £216,600 have been expended in benefits, institutional treatment has been provided for all cases of consumption for whom it had been recommended, and the finances of the Society are on a satisfactory basis. The great difficulty is the foreign-going sailor. His card has to be filled up by the officers of the ship, and enough care is not taken accurately to give his number and his name. Consequently he cannot always be identified and his money paid over to his society. The deficit at present is estimated at £50,000, lying idle in the hands of the Ministry of Health, and this sum should be available for increasing benefits and admitting these lost men to benefit. Sir Alfred Mond has promised that this matter shall be looked into. Everything should be done to help this Society, one-third of whose members, it is estimated, joined the fighting forces in the war.

Correspondence.

"Audi alteram partem."

THE PLACE OF PATHOLOGY IN MEDICINE.

To the Editor of THE LANCET.

SIR,—I have, as may be imagined, been somewhat astonished at the extensive publicity given to, and the amount of interest aroused by, a casual statement made in answer to a question put by a student after the last of a short course of lectures on general hygiene delivered to a number of very intelligent but not specially trained students. The question was: What did I think of cremation? My answer, that I look upon cremation as the most cleanly, sanitary, and convenient way of ensuring the rapid resolution of our no-longer-useful clay into its constituent elements. I pointed out, in passing, that certain objections are raised to this method of disposal of the dead, one of them being the cover it might afford to those who are too anxious to hurry their friends and others out of the world. If this but helped us to overcome the dislike that survivors have to allowing *post-mortem* examinations to be made on their dead, I for one should look upon it as something in its favour. I added that when my own time came to depart—naturally I was in no great hurry for this—I hoped a post-mortem examination would be made on my remains—and for the following reasons. One's illnesses and strains—some of them slight, some of them serious—had, I knew, left their mark on certain of my internal organs. I and my doctor friends who had been good enough to treat me, had noted certain symptoms and physical signs, on the importance of some of which we were agreed, concerning others differences of opinion arising. In view of all this I had arranged with an old friend who possessed a short record of certain portions of my clinical history, signs, and symptoms, that before my cremation these should be compared and co-related with the conditions found on post-mortem examination. Holding this as of some importance in my own case, I did not see why the same routine procedure should not be extended not only to doctors but to all intelligent people who have been trained to observe.

Whilst enjoying good health we need not trouble about these matters, but on the slightest departure from health we should make notes and call in the doctor to our aid. Just at present people—even intelligent people and officials—seem to think that the medical world is divided into water-tight compartments, in one of which are those who treat disease, in another those who investigate disease: in one those who maintain that disease and its history can only be studied at the bedside and by the clinician, in another those who garner their best harvest in the laboratory or "in a medical unit." Those who seek to divide the work of the "doctor" in this fashion are, I am satisfied, in very imperfect touch with the medical thought of the present day. There are those who are engaged on the study of the early phases of disease. They have been specially trained in this type of work, have had special opportunities of carrying it on, and the efforts of such men as Sir James Mackenzie and his disciples in this field have been fruitful beyond even their wildest hopes. On the other hand, we have amongst us men like Sir Clifford Allbutt, Henry Head, and F. W. Mott, to mention but a few outstanding names, who, in their clinical study, have called to their aid laboratory methods wherever they believe that they can derive help in the elucidation or explanation of the processes that play any part in the disturbance of functional processes or the production of organic lessons. They exploit the microscope, experimental physiology, bio-chemistry, and physics, and hand on the results of their researches to others.

During the war we have learnt much concerning the prevention of disease; we have made enormous advances in medical and surgical treatment, but best of all we have gathered into our profession a number of skilled surgeons, trained observers, and expert laboratory workers, who if they receive encouragement and support will be able to bring to bear on civil and State medicine some of the lore and experience gathered under conditions in which disease was the primary study, the individual patient receding into the background. In so far as we are able to bring the patient back to the position of foremost importance, and no further, shall we derive full benefit from all our experience gained on the field and in the war hospital.

At certain periods, owing to the development of some special phase or aspect of medicine, the other aspects are looked upon as being old-fashioned and "out of date," and one still hears of those who exhibit a contempt for research in the wards, for those who are incapable of realising the dignity of the work and opportunities of the general practitioner, of those who speak of careful work in the post-mortem room as "coffin-labelling," and of those again who are convinced that morbid histology has had its day. Many speak as though those working in these fields were seeking for the finished products of disease alone, and as though such workers had no thoughts of function and of the thousand minute changes that are associated not only with the changing structure but with impaired functions of organs and tissues. The so-called practical school has been unreasonably irked by what they consider the neglect of their work by the scientific or laboratory school, which latter again is often twitted for pinning its faith to the creed of the Red Lions, whose toast, "Here's to higher mathematics, may they be no use to anyone," achieved such vogue and fame.

In recent years the Edinburgh School of Medicine and its daughter in Manchester have, greatly to their credit, taken a forward step in teaching pathology which, to my mind, will, in the long run, have a greater bearing on the training of the medical practitioner than any step taken in recent years. All men cannot become skilled pathologists and bacteriologists, but all should be trained to interpret the signs and symptoms of disease and to allocate, more or less accurately, to each sign or group of signs some change of function, temporary or permanent, the results of pathological processes in their various stages and phases.

How can we study the beginnings of disease if we are constantly concentrating our attention and focusing our observations on the last illness of the patient? Last illnesses should no doubt be studied carefully, and all methods of investigation should be brought to bear on the complicated problems presented to us on these occasions, but every step that has led up to the final issue should, if possible, be submitted to examination. In the Edinburgh Medical School every student of pathology has placed before him the clinical notes of a case, containing a record of family and personal history, signs, and symptoms developed from time to time, the nature and results of treatment, and post-mortem findings. He has then to make a careful naked-eye and microscopic examination of the organs and tissues of the patient, and finally is called upon to write a report of the case as a whole, coördinating the findings at the various stages and explaining, as far as possible, the relation of the earlier changes to those of later date in the sequence of events.

If the medical student could, whilst writing these reports, have access to patients in the wards, suffering from diseases similar to those with which he is dealing, could examine and compare the history and clinical and laboratory findings, could note the effects of treatment, still clearer pictures of diseased conditions could be obtained. I hope this development may take place.

A few of the advantages of such an organised system are already apparent to those who have looked into the matter. How infinitely greater might these advantages become if all those who are interested in the study of disease—and this is an interest that should be shared by all educated and intelligent people—would make a point, when first they fell ill, of asking their medical men to help them to keep a record of their illnesses, would describe their sensations in their own words, and would get their doctors to interpret these sensations for them, and, finally, would give instructions that before burial or cremation their bodies should be carefully examined by someone skilled in the interpretation of lesions met with during the course of disease.

Under these conditions doctors would be called in earlier, prevention would play a far greater part in the maintenance of health, many illnesses would be nipped in the bud, the doctor would become his client's "adviser" and not merely his "repairer," the patient might confidently expect a longer, more healthy and efficient life, and medicine would become not a finer art merely but would attain a scientific level never hitherto attained.

I am, Sir, yours faithfully,

May 30th, 1921. G. SIMS WOODHEAD.

THE MEDICAL DIRECTORY, 1922.

To the Editor of THE LANCET.

SIR,—The annual circular has been posted to every member of the medical profession. We shall be grateful for its early return to us. If any practitioner fails to receive the form we will, upon request, send him a duplicate.

We are, Sirs, yours faithfully,

THE EDITORS.

7, Great Marlborough-street, London, W. 1,
June 4th, 1921.

WARMING ETHER VAPOUR FOR INHALATION.

To the Editor of THE LANCET.

SIR,—In his letter to THE LANCET of May 28th Dr. K. B. Pinson has criticised the method of heating in a tracheal insufflation anæsthesia apparatus described by me in THE LANCET of April 30th. May I point out that, in the apparatus referred to, the ether-laden air does not come into contact with the electric lamp as Dr. Pinson seems to suppose, and hence the danger of ignition of the ether must be extremely remote. Furthermore, for those who fear explosions, the construction, primarily intended for use when electricity is not available, admits of the use of hot water with equal efficacy.

As regards the practical value of heating anæsthetic vapours, I am convinced (and I believe that my conviction will be borne out by most anæsthetists) that in tracheal insufflation anæsthesia, at any rate, the adequate heating of the ether-laden air is a most important factor if pulmonary complications are to be avoided.—I am, Sir, yours faithfully,

I. W. MAGILL,
Anæsthetist, the Queen's Hospital for Facial and Jaw Injuries, Sidcup.

May 30th, 1921.

THE FEDERATION OF MEDICAL AND ALLIED SOCIETIES.

To the Editor of THE LANCET.

SIR,—It is unfortunate that in the necessarily abridged account of the speeches at the annual dinner of the Federation of Medical and Allied Societies, published in your columns last week, the invitation to the British Medical Association to officially participate in the work of the Federation, which such a large number of its members support through other societies, should have been omitted. Sir Malcolm Morris, Vice-President of the Federation and Chairman of its Medical Council, in proposing the toast of the Minister of Health, again offered the right hand of fellowship which has always been extended to the Association. He emphasised that the British Medical Association was not asked to give up any of its activities nor was there any desire to interfere with its autonomy, and he made it clear, as also did Lieut.-Colonel F. E. Fremantle, M.P., in a later toast, that the work the Federation was doing was necessary and valuable work, and that it could not be done by the Association. The speakers in referring to the success of the Federation paid generous tribute to the past work of the British Medical Association, and in so doing indicated the greater possibilities which the future promised if these two organisations, the one primarily concerned with the interests of the patient and the other with those of the doctor, could go forward hand in hand.

The report of the dinner published in the *British Medical Journal* of June 4th duly recorded the invitation again extended to the Association, and I trust that you will be able to give space for this addendum to the account you have already published.

I am, Sir, yours faithfully,
N. HOWARD MUMMERY,
General Secretary.

The Federation of Medical and Allied Societies (Inc.),
5, Vere-street, Cavendish-square, W. 1,
June 5th, 1921.

⁂ We regret that in a report which had to be reasonably shortened the omissions to which Dr. Mummery refers should have occurred. We have pointed out many times the value of a rapprochement.
—ED. L.

Surg. Lieuts. to be Surg. Lieut.-Comdrs.: J. Lorimer, L. C. D. Irvine, N. J. L. Rollason, B. Cohen, A. G. V. Elder, A. G. L. Reade, D. J. Williamson, W. C. Macartney, W. G. Evans, J. H. Lamb, and E. F. Murray.

ROYAL ARMY MEDICAL CORPS.

Capt. A. Rodd is placed on the h.p. list on account of ill-health.

Temp. Capt. G. J. McGorty to be Capt.

Temp. Capt. D. L. Lindsay relinquishes his commission and retains the rank of Capt.

The undermentioned to be temp. Lts.: D. Loughridge and W. B. Fox.

TERRITORIAL FORCE.

Capt. (actg. Maj.) G. Potts relinquishes the actg. rank of Maj. on ceasing to be specially empld.

Maj. H. A. Lake (late R.A.M.C.) to be Capt., and relinquishes the rank of Maj.

Capt. G. B. Fleming to be Maj.

Capt. J. Downie to be Maj.

J. Robinson to be Lt.

Lt. K. Pretty to be Capt.

ARMY DENTAL CORPS.

Capt. W. A. Rankin, late Dental Surg., Spec. List, to be Lt. (with the temp. rank of Capt).

The undermentioned Dental Surgs., from Spec. List, to be Lts. (with the temp. rank of Capt.): Temp. Capts. H. F. Byrne, H. O. Sumerling, C. T. Hastings, H. R. Ellis, and C. H. Pywell; Temp. Lt. J. J. Boyle.

SPECIAL RESERVE OF OFFICERS.

To be temp. Cols.: G. H. Edington, L. J. Blandford, and F. G. Proudfoot.

H. A. Leebody to be temp. Maj.

The undermentioned Capts. relinquish their commns.: O. Williams, and is granted the rank of Maj. And retain the rank of Capt.: J. A. Musgrave and D. B. Robertson.

DEFENCE FORCE.

To be Asst. Dirs. of Med. Servs.: Temp. Cols. A. D. Sharp, T.D., Def. Force; and F. H. Westmacott, T.D., Def. Force.

To be temp. Capts.: G. F. Hardy, T. B. Batchelor, W. J. Harrison, J. E. P. Coleman, and J. F. Weston.

1st (S. Midland) Fd. Amb. F.D.—To be temp. Capt.: C. W. J. Brasher.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

THE DENTISTS BILL: THIRD READING.

THE Dentists Bill, a measure to give effect to the recommendations of the Departmental Committee on the Dentists Act, 1878, was considered by a Standing Committee of the House of Commons on Tuesday, June 7th. Mr. G. R. TURTON was in the chair.

Lt.-Colonel FREMANTLE moved an amendment to Clause 1 to place all existing unregistered dentists on a special list of registration. The British Dental Association, he said, were willing to admit unregistered dentists in partnership on condition that in future all men who practised should be under proper control. This position was taken up in the public interest. The Association objected to the proposal that men who had not gone through sufficient training in the theory as well as the practice of dentistry should be placed on a register on equal terms with themselves, so that the public would be led to suppose that there was little difference between the registered and the hitherto unregistered man. This matter had been considered by the Medical Committee of the House of Commons, and that Committee resolved to support the amendment that the unqualified dentist under registration should be placed on a separate list.

Mr. BRIANT said everyone must agree that the conditions of dentistry as they existed at the moment could not be allowed to continue. There should be some check on those men who put a board outside their house upon which they called themselves surgeon-dentists and professors. These advertisements unfortunately meant a great deal to some people.

Colonel WEDGWOOD said that the amendment supported the continuance of a corporation of vested interests in dentistry, similar to that of the British Medical Association in regard to medicine. It sought to give the dental practitioners an enormous advantage, raising their status and creating for them a monopoly. At the present time the majority of the working classes were attended by the unregistered dentists. The unregistered men were now being raised under the Bill to the status of the qualified practitioners. That would inevitably mean higher prices for dentistry, and although the unregistered dentist was to be registered the amendment would still draw a distinction between the qualified and the unqualified dental surgeon.

Mr. SEDDON said that there were approximately 10,000 men in this country engaged in the practice of dentistry, who had done so as unregistered practitioners for five years. He held that these men had gained the confidence of the public. They all wanted to raise the standard of dentistry, but he did not think the amendment would help to that end. He asked the British Dental Association to adopt the new system in a generous spirit.

Mr. HARTSHORN hoped the Committee would not accept the amendment, which aimed at making an inner and an outer circle, and the advantage would be for those who had the privilege of being in the inner circle. They would be known as the aristocracy of the profession.

Major MOLSON said to-day there were not sufficient dentists in the country. There were only about 1000 practising at the present time as registered dentists, and the Bill would cause the registration of about 9000 more. He had seen some of the work done by unqualified dentists, and he knew how great was the necessity for raising the standard. He thought it would be a good thing to have two stages—A and B—so that those in the lower category after the specified period could pass to the higher category.

Sir A. MOND (the Minister of Health) said that as the amendment stood the unregistered dentist would not be placed on the register. He did not believe in dividing the profession into sheep and goats. If the amendment were accepted it would cut right across the whole foundation of the Bill and would wreck it.

Colonel FREMANTLE said that the British Dental Association did not wish to wreck the Bill, and he withdrew the amendment.

Mr. SEDDON moved an amendment to Clause 3 to include membership of the National Dental Association or the Chemists' Dental Society, as qualifications for admission to the Dental Register.—On a division the amendment was defeated by 20 votes to 6.

On Clause 4, which provides that all the directors, managers, and operating staffs of dental companies shall be registered dentists: Sir T. ROBINSON moved that only one of the directors need be registered.

Sir A. MOND said that one was too few. As a compromise he would agree to a provision that the majority of the directors should be registered dentists.

The amendment was withdrawn and the suggested compromise agreed to, reference to managers being omitted.

After further discussion the Committee stage of the Bill was completed, and the measure was ordered to be reported to the House.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 1ST.

Post-war Disability Pensions.

Major Sir **BERTRAM FALLE** asked the Financial Secretary to the Admiralty when the post-war disability scale of pensions would be applied to the Royal Navy and Royal Marines.—Mr. **AMERY** replied: The post-war scales will become operative 30 days after the official termination of the war. It is anticipated that detailed particulars will be ready for publication at an early date. The regulations governing the application of the post-war scales to pre-war disability pensioners who have served in the present war are now practically complete, and as soon as some minor details have been settled the work of re-assessing these pre-war pensions will be taken in hand.

Pure Atmosphere and Public Health.

Mr. **TREVELYAN THOMSON** asked the Minister of Health whether his attention had been drawn to the appreciable improvement in the health of urban populations at the present time, attributable by many medical authorities to the purer condition of the atmosphere due to reduced coal consumption; and had he considered the possibility of securing these same health advantages by means of measures for smoke abatement when coal consumption again became normal.—Sir **ALFRED MOND** replied: The time during which the consumption of coal has been reduced has not been sufficient for the confirmation or contradiction of the suggestion in the first part of the question. The whole question of the pollution of the atmosphere by smoke and other noxious vapours is receiving the consideration of a Departmental Committee under the chairmanship of Lord Newton. I have no doubt that the Committee are fully conversant with the aspects of the problem to which the honourable Member refers.

National Health Insurance.

Mr. **WILKIE** asked the Minister of Health whether he had received representations from societies approved under the National Health Insurance Acts who had difficulties in meeting their administrative costs out of existing allowances; whether he was aware that the increased postal charges would add to these difficulties; and whether he could say when the measure for the relief of the societies by increasing the administration allowance would be brought before the House. 2. Sir **THOMAS BRAMSDON** asked the Prime Minister whether it was the intention of the Government to give immediate effect to the recommendations of the Departmental Committee on National Insurance Administration.—Sir **ALFRED MOND** replied: The answer to the first question is in the affirmative. The Departmental Committee appointed by my predecessor to go into the whole question took account of the effect of increased postal charges on the societies. I hope at an early date to introduce a Bill to give effect to the recommendations of the Committee which have been presented to Parliament.

Sir **WALTER DE FRECE** asked the Minister of Health whether his department had considered the likelihood that when the insurance year closes on July 3rd several million insured persons would be in arrear with their contributions owing to the amount of unemployment; whether such insured persons would, unless they paid 12s. before Oct. 31st to liquidate 25 contributions in arrear, be disqualified from receiving sickness, disablement, and maternity benefit for a whole 12 months; whether he could take any steps to ease what might become a very serious situation; and whether, in particular, he would consider the possibility of allowing Approved Societies to use some of their surplus funds, as ascertained by the recent valuation, to assist in paying off members' arrears. 2. Sir **WALTER DE FRECE** asked the Secretary to the Treasury whether the Government would, in view of the vast volume of unemployment, consider the possibility of extending the excusing of contributions under the National Health Insurance Act to persons while unemployed.—Sir **A. MOND** replied: The honourable Member has correctly stated the position of insured persons who will be in arrear with their contributions at the end of the insurance contribution year. The matter has engaged the close attention of the department and has already been discussed with a representative conference of Approved Societies. As a result it has been decided to ease the situation by allowing an insured person an extended period from July to the end of November in which he may make the comparatively small payment necessary to avoid or mitigate any reduction of benefit during the following calendar year. These yments are on a graduated scale varying from 1s. to s. in accordance with the extent of the arrears, and in the extreme case where the arrears exceed 26 a single payment of 5s. would qualify the insured person for sickness benefit at 8s. a week (in addition to any amount added by way of additional benefit) with full maternity benefit, and the rate of sickness benefit would be increased by 1s. a week for each further instalment of 1s. paid during the five months. There is nothing to prevent a society which has a disposable surplus in valuation submitting for the approval of the department a scheme for utilising the whole or part of the surplus for the remission of arrears.

Colonial Medical Service.

Lieutenant-Colonel **FREMANTLE** asked the Secretary for the Colonies whether he intended as recommended by the Colonial Medical Services Committee to appoint a Director-General of the Colonial Medical Service who would, inter alia, advise the Secretary of State and the permanent staff of the Colonial Office as to all questions relating to the personnel of the Colonial Medical Service.—Mr. **WOOD** replied: The recommendations of the Colonial Medical Services Committee are at present being considered in connexion with the observations of the Colonial Governments. I cannot yet make any statement as to the decision on the proposal to appoint a Director-General of the Colonial Medical Service.

Colonel **FREMANTLE** also asked the Secretary for the Colonies whether he had sanctioned a minimum salary of £600 per annum, with pension, for colonial medical officers as recommended in the Report of the Colonial Medical Services Committee.—Mr. **WOOD** replied: No, Sir, the differences in the resources of the several colonies are so great and the conditions under which their medical officers serve so diverse that I see no prospect of it being possible to insist on Colonial Governments adopting the minimum in question as a hard-and-fast rule. In a number of the more prosperous colonies the local governments have adopted, and in some cases exceeded, the minimum.

Colonel **FREMANTLE**: Is it conceivable that any decent respectable medical man can be obtained to go abroad for a less salary than that amount?—The **SPEAKER**: That does not arise out of the question.

THURSDAY, JUNE 2ND.

Secrecy in Medical Practice.

Colonel Sir **ARTHUR HOLBROOK** asked the Minister of Health whether he was aware that the Insurance Committee of the area comprising Bramley, near Basingstoke, received an intimation that a portion of the Exchequer grant payable to them will be withheld in consequence of a local medical practitioner having declined to give information detrimental to one of his patients acquired by him in the course of his profession, such information having been called for at the behest of a rich corporation with whom the man was insured; and whether he would take action to secure that a doctor shall not be penalised for doing his duty to his patient.—Sir **A. MOND** replied: In the case to which this question appears to refer an Approved Society sought to obtain the opinion of the medical referee of the Ministry on the question of the incapacity for work of one of their members who was claiming sickness benefit, and I regret that the insurance practitioner has definitely declined to give any particulars as to the history and condition of the patient likely to assist the medical referee, notwithstanding the provision in his terms of service which clearly requires him to do this. In these circumstances it has become necessary to inform the doctor that a portion of the Exchequer grant forming part of his remuneration must be withheld, the grant being payable only if the terms of service were complied with. But in accordance with the provision of the Regulations any representations which the doctor may wish to make in the matter will first be considered.

Mothers' Pensions.

Mr. **TYSON WILSON** introduced a Bill to provide for pensions for mothers which was read a first time.

FRIDAY, JUNE 3RD.

Public Health (Officers) Bill.

The House considered the Public Health (Officers) (No. 2) Bill as amended in the Standing Committee.

On Clause 1, which deals with the tenure of office of a medical officer of health, Sir **P. MAGNUS** moved an amendment to insert at the beginning of the Clause the words "in cases to which this section applies."—The amendment was agreed to.

Sir **P. MAGNUS** moved to add at the end of the Clause the words: This section applies to—(*a*) the medical officer of health of a county borough where any portion of the salary of the medical officer was paid out of moneys voted by Parliament before it was constituted a county borough; (*b*) the medical officer of health of a county district any portion of whose salary is paid out of the county fund of the county in which the district is situate and charged to the exchequer contribution account.

Dr. **MURRAY** asked for an explanation of this amend-in at the request of the Ministry of Health in order to restrict the operation of the Bill to certain local authorities which had special advantage given to them previously.—On a division the amendment was carried by 100 votes to 17.

The Bill was read a third time and passed.

Dogs Protection Bill.

Sir F. BANBURY, in moving the second reading of the Dogs Protection Bill, said the Bill had already passed second reading on three different occasions, twice without a division, and once by a considerable majority. If any honourable Member was under the impression that by passing it he would injure the cause of vivisection he would read an extract from THE LANCET, dated May 31st, 1919: "This is not to say that such knowledge could not have been acquired in any other way." Therefore having the admission of THE LANCET,[1] the well-known and recognised authority of the medical profession, it was evident that the knowledge which the medical profession said was acquired by experiments on dogs could be acquired in another way. The right hon. baronet concluded by reading a passage in praise of the dog written by an American poet and writer, whose name, he said, he regretted he did not know.

Sir WATSON CHEYNE said this was the third or fourth time that he had had to speak on this Bill, and naturally it was rather difficult to say anything new. He would summarise the chief objections which they as a scientific and medical profession had against the measure. He was a dog-lover—all his friends were dog-lovers—and they sympathised with the passage read by Sir F. Banbury. It was not that they disliked dogs, but that they could not afford to lose the experience that could be gained from them. The first thing that they asserted, in contradiction to THE LANCET, was that there were many fields of knowledge that they must explore if they were to advance the science of medicine and do their duty in the fight against disease. Some of the fields of observation which they gathered from the dog were quite necessary. It was not simply a question of vivisection. The animals that were used in experiments fell into four classes: these were the small rodents, rats, mice, and guinea-pigs; dogs; cats to a smaller extent; horses, rabbits, and apes. Other animals were only occasionally used. Rodents were almost entirely used in connexion with investigations respecting infectious diseases. Horses were used not so much for experiments as for commercial purposes and for the production of sera, such as tetanus antitoxin, which saved so many lives during the war. The animal had to be infected with the disease. The dog and the ape were really the only two animals from which they got the main part of their knowledge as regarded the processes of health and disease. It was quite true that most of the work could be done with apes, not so conveniently in some cases, certainly not so cheaply. But one or other must be used for various reasons. In the first place, if they wanted to get results which they could apply in the treatment of disease they must have animals whose mode of life resembled man's and whose metabolism and chemical changes in their bodies were on the same lines as man's. He knew that Sir F. Banbury was not out for humanitarian purposes. It did not matter to him what animals were vivisected so long as they were not dogs, and therefore he said why not use apes? There were various objections. In the first place there were not many apes in this country, and in the second place the apes were not so easily handled. They were not so tame as dogs; they were more like spoiled children. Put a dressing on a dog and he did not trouble so much about it. In a few hours he apparently forgot about it; but the ape did not forget. He never rested satisfied until he had torn open the stitches and vitiated the whole experiment. It would be extremely difficult to carry out many delicate operations which did not hurt the animals in the least. They must take account of the question of expense. The men who were engaged in this sort of work were in the great majority of cases poor men. They did not spend their money on pleasure, but on instruments and other things they wanted for their experiments; and to ask the poor man to buy such expensive animals as apes was out of the question. He would be very much surprised if the House would pass any vote for a laboratory if they found that apes were being used instead of dogs. There would be an economical outcry against it. The results which had been got from experiments on dogs were of the greatest value and were the groundwork of our whole knowledge of the healthy processes of human nature. Physiology, the science of health, was based almost entirely on observations on dogs. It was said by opponents that they would not so much object if the experiments led to a practical result. But it did not do to despise knowledge because it had no immediate utilitarian outlook. Almost all the great sciences had begun in insignificant things.—The honourable Member was still speaking at five o'clock when by the rules of the House the debate stood adjourned.

HOSPITAL FINANCE:
REPORT OF THE VOLUNTARY HOSPITALS COMMITTEE.

THE final report of the small committee over which Viscount Cave presides contains the following important recommendations:—

(1), (2) That a Hospitals Commission and Voluntary Hospitals Committees be formed for the country as a whole, the King Edward's Hospital Fund for London continuing to perform the functions of the latter for the Metropolitan Police District.

(3), (4) That Poor-law guardians be authorised to enter into arrangements as to the use of infirmaries, and that county councils be empowered to contribute to the expenses of voluntary hospitals committees.

(5) That failing the provision in the National Health Insurance Acts of a "hospital benefit," the courts be authorised to award to hospitals compensation under the Employers' Liability and Workmen's Compensation Acts.

(6) That local authorities be authorised to pay the cost of the treatment in hospitals of persons in their employ.

(7) That the payment out of technical education funds of grants for the training of nurses be considered.

(8) That provision be made for obtaining and tabulating returns of cases treated in hospitals.

(9), (10), (11) That all contributions by employers to hospital funds be allowed as deductions from profits for income-tax purposes, that where the payment to a hospital of a testamentary gift of residue is delayed for more than a year, the hospital be authorised to claim repayment of income-tax, and that legacy and succession duty on testamentary gifts to hospitals be remitted.

(12) That Parliament be asked to sanction a temporary grant of £1,000,000 to be expended under the direction of the Hospitals Commission in the assistance of hospitals which require it.

A last clause states that the Hospitals Commission should be authorised during a period of two years to recommend grants for the extension and improvement of hospitals subject to like contributions being made from private sources.

These recommendations if adopted will require legislation or executive action.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At the Congregation held on Saturday, June 4th, the following degrees were conferred:—

M.D.—C. S. Clarke and L. M. Weeks, Caius.

Ph.D.—C. G. L. Wolf, Christ's.

M.B., B.Ch.—H. Barbash, St. John's; and L. W. Batten, Sidney.

B.Ch.—W. H. Marshall, Pembroke.

Diploma in Psychological Medicine.—The dates for the next examinations have been fixed as follows: for Part I. (Anatomy and Physiology of the Nervous System and Psychology) Oct. 11th, 12th, and 13th, 1921; for Part II. (Neurology and Psychiatry) Nov. 30th, Dec. 1st, and 2nd, 1921. A course of instruction for the Diploma will be held in Cambridge from July 18th to August 20th. Lectures and practical work will be given by Dr. J. P. Lawson (Psychology), Dr. C. R. A. Thacher (Anatomy and Physiology of the Nervous System), Dr. J. F. E. Prideaux and Dr. C. S. Myers (Psychopathology), Dr. W. H. R. Rivers (Psychology and Pathology of Dreams), Dr. M. A. Archdale (Mental Diseases). Those who wish to take the course are requested to send their names, if possible, before July 10th, to the Secretary of the D.P.M. Committee, Psychological Laboratory, Cambridge, from whom further particulars may be obtained.

UNIVERSITY OF MANCHESTER.—Mr. Harold Robinson, D.Sc., Senior Lecturer in Physics and Assistant Director of the Physical Laboratories, has resigned his appointment. The Turner Medical Prize has been divided between Mr. G. V. Ashcroft and Miss Margaret Single.

THE PRINCE OF WALES AND THE RED CROSS.—The message sent by the Prince of Wales to the League of Red Cross Societies in connexion with a world-wide campaign to increase the membership of the Red Cross in all countries reads as follows: "I am very glad to learn from you that the Red Cross Societies of the world, under the auspices of the League of Red Cross Societies, are undertaking a campaign for membership to enable them to carry on the peace work of the Red Cross. The effort which the League of Red Cross Societies is making to serve humanity in peace time as well as in war, has my heartiest approval, and I trust that your campaign will result in a very large addition to the membership of National Red Cross Societies." Other messages of warm approval have been received from Lord Robert Cecil, from the President of the Republic of Czecho-Slovakia, from Mr. Samuel Gompers, Cardinal Mercier, and Mr. Herbert Hoover. The aim of the British Red Cross Society is to enlist the service of the whole country in the work of healing. It is hoped that volunteers will offer their services to the British Red Cross Society to help the suffering in peace time in the same spontaneous manner in which they came to the aid of the sick and wounded in war time. The peace activities of the British Red Cross Society include the after-care of the disabled ex-Service man, aid to the hospitals, work at infant welfare centres and day nurseries, and assistance to the clergy and educational authorities. The Red Cross, members are reminded, should be available on all occasions when the clergy and heads of educational establishments, such as orphanages, require the simple assistance which is often lacking on such occasions as school and choir treats and annual outings. The glamour and the brassards may have disappeared, together with the ornamental people to whom the Cross of Geneva was an excuse to smile for press photographers; the hard work still remains on lines perhaps less interesting and certainly more obscure.

---

[1] See page 1253 for comment upon this sort of quotation. The reference was to a particular series of results.

Federation of Medical and Allied Sciences.—A meeting of the Medical Council of the Federation was held at 11, Chandos-street, W., on May 31st, when consideration was given to the possible means of providing additional medical services to supplement the existing resources of practitioners and bring within reach of all sections of the community modern methods of treatment now largely confined to the well-to-do. The Organising Committee of the National Provident Scheme for Hospital and Additional Medical Services had submitted to the Federation its proposals and these were fully discussed and explained by Dr. Gordon Dill. It was resolved to obtain the opinions of the constituent Societies with a view to again pressing for a public and independent inquiry into the working of the medical benefit clauses of the National Insurance Act. The intention was stated to make the inquiry in a constructive spirit and with a genuine desire to retain all that is good and add what may be lacking.

It was decided that the annual meeting should be held on June 28th next. A number of medical men were elected individual members of the Federation.

Royal Sanitary Institute.—Preliminary arrangements for the Congress to be held at Folkestone, from June 20th to 25th, have now been issued. The President will be Lord Radnor, and the hon. local secretaries are Mr. A. F. Kidson, town clerk, and Dr. M. G. Yunge-Bateman, medical officer of health. The sections will be as follows:—(*a*) Sanitary Science and Preventive Medicine; President: Sir Leslie Mackenzie, M.D.; Recording Secretary: Dr. W. J. Howarth. (*b*) Engineering and Architecture; President: Major W. H. Prescott, M.P.; Recording Secretary: Mr. W. C. Tyndale. (*c*) Hygiene of Maternity and Child Welfare, including School Hygiene; President: Mrs. H. A. L. Fisher; Recording Secretary: Dr. Charles Porter. (*d*) Personal and Domestic Hygiene; President: The Mayoress of Folkestone (Mrs. Reginald G. Wood); Secretaries: Mrs. J. E. G. Calverley, Mrs. Sydney Weston. (*e*) Industrial Hygiene; President: Lord Burnham; Recording Secretary: Dr. E. H. Snell. Fellows, members, and associates of the Institute are supplied with tickets for the Congress on application to the Secretary before the Congress, or tickets can be obtained at the Reception Room during the meeting. To those not connected with the Institute, Congress tickets, at £1 11*s.* 6*d.* each, can be obtained from the hon. secretaries, Royal Sanitary Institute Congress, Town Clerk's Office, Folkestone. Ladies' tickets (not including copies of the proceedings), 10*s.* 6*d.* each.

Livingstone College. — Commemoration Day, May 27th, was celebrated at Livingstone College, Leyton, Sir George Makins presiding. Dr. L. E. Wigram, the retiring Principal, said that though his health prevented him from continuing as Principal of the College his work in connexion with it as a lecturer would not cease. Referring to new developments at the institution, he said women students would be admitted and next session arrangements would be made for them as residents. Sir George Makins said the aim of the missionary was to minister to the souls and bodies of his fellow men. To fulfil this dual object it was necessary that he should have, in addition to his theological training, some knowledge of medical things. Sir George Makins emphasised the great value of partial medical training in everyday life, instancing the great help it had been in the work of orderlies and V.A.D.'s during the recent war, and its uses in the Mercantile Marine. If the benefit of partial medical training was so felt in a civilised country, he said, how much more necessary must it be in the mission field where a man was far from qualified medical aid. Such knowledge as could be obtained at Livingstone College must be immensely helpful. Dr. C. F. Harford, representing the Committee, in proposing a vote of thanks to Sir George Makins, expressed the regret of the Committee at Dr. Wigram's enforced resignation, and wished him many years connexion with the College as lecturer. He welcomed in the name of the Committee Dr. T. Jays as the new Principal, and felt sure that he was the right man to fill the post.

St. Thomas's Hospital Medical School.—The distribution of prizes by the Duke of Connaught will take place on Tuesday, June 21st, at 3 p.m.

Royal Institution of Great Britain.—An extra Friday evening discourse will be held on June 17th, at 9 o'clock, when Sir J. J. Thomson, F.R.S., will lecture on "Chemical Combination and the Structure of the Molecule."

Rontgen Society.—At the meeting of the Society to be held at 35, Russell-square, London, W.C., on June 16th, at 8.15 p.m., there will be a discussion on the Physics of the X Ray Tube. All interested are invited to attend.

A Dining Club, composed of all past and present members of the honorary and house staffs of the Hospital for Sick Children, Great Ormond-street, held its first dinner on June 1st. Sixty-three members attended, including many who were house officers of the hospital as far back as 1880–1890, when Sir Thomas Barlow presided.

A Tribute to the Memory of Sir Morell Mackenzie.—On Sunday, June 5th, a group of well-known laryngologists assembled at Wargrave to pay a tribute to the memory of Sir Morell Mackenzie, who had a residence in the little Berkshire village, and is buried in the churchyard of St. Mary's, Wargrave. A special service was held in the churchyard by the Rev. S. M. Winter, after which Mr. Mark Hovell and Dr. James Donelan, former assistants to Sir Morell Mackenzie, placed a laurel wreath upon the tomb. Mr. Hovell, Sir StClair Thomson, and Sir James Dundas-Grant, gave short addresses. Dr. Irwin Moore, who had recently acquired Sir Morell Mackenzie's house at Wargrave, acted as host to a gathering which he had been instrumental in assembling.

National Hospital for Diseases of the Heart. A Systematic Post-Graduate Course of Instruction in Diseases of the Heart will be held at this hospital from July 11th to 23rd. Practical instruction will be given in the use of the polygraph, electrocardiograph, and other instruments. Systematic and clinical instruction will be given in the wards and the out-patient department throughout each day. The number admissible is limited. Applications should be made as soon as possible to the Secretary, National Hospital for Diseases of the Heart, Westmoreland-street, London, W.1.

Ladies' Medical Golfing Society.—A meeting will be held at Beaconsfield Golf Club on Wednesday, June 15th. The annual subscription to this society is 5*s.*; and those eligible for election include medical women and the wives, sisters, and mothers of medical men. Further particulars can be obtained from the hon. secretary, Mrs. Laming Evans, 50, Seymour-street, London, W.1.

Medical Golfing Society.—The 1921 tournament will be held on Thursday, June 16th, at Walton Heath Green fee of 2*s.* 6*d.* for the day. Trains leave Charing Cross and London Bridge for Tadworth. Thence by conveyance to the course. A Challenge Cup for the Medical Golf Championship has been presented by the The Lancet. This championship is played annually at the meeting of the Medical Golfing Society, and the Cup is held for the year by the player on the Medical Register who makes the best scratch return v. Bogey. A replica of the Cup is also given as a memento. The "Henry Morris" Challenge Cup and the Medical Golfing Society's Gold Medal will be awarded for the best return under handicap. First, second, and a prize for the best last nine holes will be given in each class. No player can take the first or second, and the prize for the best nine holes. Class I. Handicaps 8 and under. Class II. Handicaps over 8. Handicap limit 18. (Members of the Walton Heath Golf Club will deduct two from their handicaps.) Cards may be handed in till 7.30 p.m. A Foursome Sweepstake will be arranged in the afternoon. Players who want caddies (fee 5*s.*) must make their own arrangements with the Caddy Master at Walton Heath. Anyone on the Medical or Dental Register is eligible to join this society by payment of the annual subscription of 5*s.* Entries should be sent on or before Tuesday, June 14th, to Dr. L. E. Creasy, hon. secretary and treasurer, The Medical Golfing Society, 36, Weymouth-street, London, W.1.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Thursday, June 16th.

GENERAL MEETING OF FELLOWS: at 8.30 P.M.

Discussion: on "The Problem of the Private Clinic System in Great Britain." To be opened by Sir Thomas Horder. The following will also speak:—Dr. G. C. Anderson, Mr. W. Clayton-Greene, Mr. W. S. Dickie, Mr. Bishop Harman, Dr. A. F. Hurst, Dr. Drury Pennington, Sir Humphry Rolleston, Dr. Gilbert Scott, Dr. Maurice Wright.

Fellows desiring to take part in the discussion are invited to send in their names to the Hon. Secretaries.

Tuesday, June 21st.

GENERAL MEETING OF FELLOWS: at 5 P.M. Ballot for election to the Fellowship.

MEETINGS OF SECTIONS.

Thursday, June 16th.

SECTION OF DERMATOLOGY: at 5 P.M. (Cases at 4.30 P.M.)

Cases will be shown.

Friday and Saturday, June 24th and 25th.

SECTION OF STUDY OF DISEASE IN CHILDREN.

Provincial Meeting at *Reading.*

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY, June 17th.—7.15 P.M., Demonstration. 8.15 P.M., Annual General Meeting. Paper:—Major R. Knowles: The Mechanism and Treatment of Snake Bite in India.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY, June 14th, and THURSDAY.—5 P.M., Croonian Lectures:—Dr. F. L. Golla: The Objective Study of Neurosis.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, June 13th.—12.15 P.M., Dr. Burnford: Pathological Demonstration. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. Dr. Simson: Diseases of Women. Dr. Morton: X Ray Department. 4.15 P.M., Lecture:—Dr. Arthur Saunders: Gastric Disorders in Old Age.

TUESDAY.—10 A.M., Dr. Robinson: *Gynæcological Operations and Visit to Wards.* 2 P.M., Mr. Banks Davis: Diseases of the Throat, Nose and Ear. Dr. Pernet: Skin Department. Dr. Burnford: Medical Outpatients. 5 P.M., Lecture:—Dr. Pritchard: Chronic Infective *Processes.*

WEDNESDAY.—10 A.M., Mr. MacDonald: Genito Urinary Department. 12 noon. Mr. Sinclair: Surgical Diseases of the Abdomen. 2 P.M., Mr. Gibb: Eye Department. Mr. Donald Armour: Demonstration of Cases, Surgical Wards.

THURSDAY.—10.30 A.M., Dr. Simson: *Gynæcological* Demonstration. 12 noon, Dr. Scott Pinchin: Diseases of the Heart. 2 P.M., Mr. Bishop Harman: Eye Department. Mr. Baldwin: Orthopædic Department. 5 P.M., Special Lecture:—Dr. Harry Campbell: Observations on *Diet.* (Open to all Medical Practitioners.)

FRIDAY.—10 A.M., Dr. Grainger Stewart: Neurological Demonstration. 2 P.M., Mr. Tyrrell Gray: Surgical Out-patients. 2.30 P.M., Mr. Addison: Visit to Surgical Wards. 5 P.M., Lecture:—Mr. Baldwin: Surgery of the Rectum (1).

SATURDAY.—10 A.M., Dr. Arthur Saunders: Medical Diseases of Children. 2 P.M., Mr. Sinclair: Surgical Out-patients. Dr. Owen: Medical Out-patients.

Daily:—10 A.M., Visit of Post-graduates to Wards. 2 P.M., In-patient, *Out-patient Clinics* and Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, June 13th.—10 A.M., Mr. W. E. Tanner: Surgical Out-patients. 2 P.M., Dr. A. J. Whiting: Medical In-patients. 2.30 P.M., Mr. J. B. Banister: Gynæcological.

TUESDAY.—9.45 A.M., Lt.-Col. R. H. Elliot: Eye Operations and Cases. 2.30 P.M., Dr. J. Metcalfe: X Ray Department. 3 P.M., Lecture:—Mr. C. H. Hayton: Anatomy *of the Nose* and Accessory Sinuses.

WEDNESDAY.—2 P.M., Mr. C. H. Hayton: Throat Operations. 2.30 P.M., Dr. W. J. Oliver: Dermatological. 3 P.M., Lecture Demonstration:—Mr. W. E. Tanner: Clinical Pathology and Differential Diagnosis of Scrotal Enlargements.

THURSDAY.—2 P.M., Mr. N. Fleming: Eye Department. 2.30 P.M., Mr. J. B. Banister: *Gynæcological* Operations. Dr. J. Metcalfe: Radiology.

FRIDAY.—2 P.M., Dr. C. E. Sundell: Diseases of Children. 3 P.M., Lecture Demonstration:—Mr. T. H. C. Benians: Blood Examination in Diagnosis. 5 P.M., Dr. Provis and Mr. Benians, Venereal Department.

SATURDAY.—10.30 A.M., Mr. W. E. Tanner: Operations. 3 P.M., Mr. H. W. Carson: Surgical In-patients.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C. 1.

MEDICAL SCHOOL.

MONDAY, June 13th.—2 P.M., *Dr. Hinds Howell*: Out-patient Clinic. 3.30 P.M., Dr. Aldren Turner (Lecture Room): Demonstration of Cases.

TUESDAY, June 14th.—2 P.M., Dr. Grainger Stewart: Out-patient Clinic. 3.30 P.M., Lecture:—Mr. Armour: Surgical Treatment *of* Spinal Cord Tumours (2).

THURSDAY, June 16th.—2 P.M., Dr. Farquhar Buzzard: Out-patient Clinic. 3.30 P.M., Lecture:—Dr. Farquhar Buzzard: Encephalitis Lethargica.

FRIDAY, June 17th.—2 P.M., Dr. Gordon Holmes: Out-patient Clinic. 3.30 P.M., Dr. Collier (Lecture Room).

NEUROLOGICAL OPHTHALMOLOGY.

WEDNESDAY, June 15th.—3.30 P.M., Mr. Leslie Paton Papillœdema.

Fee for Post-Graduate Course £7 7s.

C. M. HINDS HOWELL, Dean.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Turner-street, Mile End, E.

Courses of Lectures:—

A Course of Fourteen Lectures on Psycho-Neuroses, to be given by Dr. M. Culpin in the Clinical Theatre of the Hospital. Open to Students of the Hospital and to Members of the Profession.

TUESDAY, June 14th.—5.15 p.m., Lecture XII: Treatment.

FRIDAY.—5.15 P.M., Lecture XIII: Association Methods.

Advanced Lectures in Physiology, to *Students of the* University and to others interested in the subject.

A Course of Eight Lectures on Reception of Sensory Stimuli, to be given by Prof. H. E. Roaf in the Physiology Theatre.

THURSDAY, June 16th.—4.30 P.M., Lecture VI.

SURGICAL UNIT.—A Special Course of Ten Lectures on Advanced Surgery in the Unit Theatre to Post graduates and Senior Students.

TUESDAY, June 14th.—4.15 P.M., Mr. R. Warren: Ventral Hernia.

WEDNESDAY.—4.15 P.M., Mr. R. Warren: Suppuration of the Lung.

UNIVERSITY OF LONDON.

Advanced Lectures to Students of the University and to others interested in the subjects.

A Course of Four Lectures in Pharmacology, on Some Actions of Foodstuffs in the Production and Treatment of Disease, to be given by Prof. E. Mellanby at the Royal College of Surgeons, Lincoln's Inn-Fields, W.C.

MONDAY, June 13th, and TUESDAY.—5 P.M., Lectures III. and IV.

ST. BARTHOLOMEW'S HOSPITAL (UNIVERSITY OF LONDON), West Smithfield, E.C.

A Course of Eight Advanced Lectures in Physiology, to be given in the *Physiological* Laboratory, to Students of the University and others interested in the subject.

TUESDAY, June 14th.—4.30 P.M., Lecture VII.:—Dr. H. H. Dale: Anaphylaxis.

A Course of Four Advanced Lectures in Medicine, to be given in the Surgical Lecture Theatre, *to* Students of the University and others interested in the subject.

MONDAY, June 13th, WEDNESDAY and FRIDAY.—5 P.M., Prof. F. R. Fraser: The Therapeutic Use of Digitalis (Lectures I., II., and III.).

THE HOSPITAL FOR SICK CHILDREN, *Great Ormond-street*, W.C.

THURSDAY, June 16th.—4 P.M., Lecture:—Dr. Thursfield: Mongols.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, E.

A Course of Post-graduate Clinical Lectures and *Demonstrations* in the Board Room of the Hospital, free to Medical Practitioners and Students of Medicine.

MONDAY, June 13th.—4 P.M., Mr. W. P. T. Atkinson: Tinea Tonsurans and its Treatment by X Rays.

TUESDAY.—4 P.M., Dr. S. A. Owen: The Premature Baby.

THURSDAY.—12 noon, Mr. V. Nesfield: The Treatment of Corneal Ulcers by Subconjunctival Injection of Phenolaine Solution.

FRIDAY.—3.30 P.M., Dr. J. L. Bunch: Skin Diseases in Children.

TAVISTOCK CLINIC FOR FUNCTIONAL NERVE CASES, 51, Tavistock-square, W.C.

A Course of Ten Lectures on Elementary Psychotherapy, to be given by Dr. H. C. Miller, at the Kingsway Hall, Kingsway, W.C.

FRIDAY, June 17th.—5.15 P.M., Lecture VII., Analytical Methods: Reassociation and Readjustment; Word Association; Hypnoidal Analysis.

INSTITUTE OF PATHOLOGY AND RESEARCH, St. Mary's Hospital, in the Lecture-room of the *Bacteriological Department.*

A Course of Lectures on Pathological Research in its Relation to Medicine, open to all Members of the Profession and Students.

THURSDAY, June 16th.—4.30 P.M., Prof. W. Bulloch: Use and Abuse of Scientific Medical Literature.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.

TUESDAY, June 14th.—4.30 P.M., Lecture:—Dr. E. B. Leech: Blood Pressure.

Appointments.

Armstrong-Jones, Sir R., M.D. Lond., has been appointed a Visitor in Lunacy.

Brown, A. Middleton, M.D. Aberd., D.P.H., Medical Officer of Health and Schools Medical Officer for the City of Hereford.

McPherson, J. M., M.B., Ch.B. Glasg., Medical Officer of Health to the Swansea Rural District Council.

Warburton, G. B., Ch.M., F.R.C.S., Visiting Surgeon to the Crumpsall Institution and Infirmary, Manchester.

Webster, J. H. Douglas, M.D. Edin., M.R.C.P. Edin., Honorary Physician-in-Charge of Department of Physical Medicine at the Middlesex Hospital.

Young, W. A., B.Sc., M.B., B.S., M.R.C.S., L.R.C.P., Pathologist to St. John's Hospital for Diseases of the Skin.

Jessop Hospital for Women, Sheffield: Hall, R. J. B., M.B., Ch. B. Otaga, Senior Resident Officer, and Jaede, C. H., M.B., Ch.M. Sydney, and Sohpianopoulos, G. J., M.R.C.P. Lond., M.R.C.S., Assistant House Surgeons.

St. Thomas's Hospital: Squires, F. V., M.R.C.S., L.R.C.P. Lond., Back, G. A., M.R.C.S., L.R.C.P. Lond., Granger, E. D., M.B., B.S. Lond., Hamilton, C. K. J., M.B., B.Ch. Oxon., Liang, P. T., B.Ch. Cantab., D.T.M., Whitelaw, A. D., M.R.C.S., L.R.C.P. Lond., Tracy, G. D. C., M.R.C.S., L.R.C.P. Lond., and Humfrey, S. H. G., M.R.C.S., L.R.C.P. Lond., Casualty Officers and Resident Anæsthetists; Maxwell, L. B., M.R.C.S., L.R.C.P. Lond., Hawley, A. T., M.R.C.S., L.R.C.P. Lond., Kendall, G. M., M.B. Cantab., and Cardell, J. D. M., M.R.C.S., L.R.C.P. Lond., Resident House Physicians; Hobbs, F. B., M.B., B.Ch. Cantab., Resident House Physician for Children; Garnett, D. G., M.R.C.S., L.R.C.P. Lond., Halliwell, A. C., M.B., B.Ch. Cantab., Low, W. A., M.R.C.S., L.R.C.P. Lond., and Spence, D. B., M.R.C.S., L.R.C.P. Lond., Resident House Surgeons. Brockman, E. P., M.B., B.Ch. Cantab., Resident Orthopædic House Surgeon; Marriner, H. I., M.R.C.S., L.R.C.P. Lond., Resident House Surgeon for Ear, Nose, and Throat; Robinson, R. H. O. B., M.B., B.Ch. Cantab., House Surgeon to Block 8; Orme, E. S., M.R.C.S., L.R.C.P. Lond., Senior Obstetric House Physician; Cranstoun, G., M.R.C.S., L.R.C.P. Lond., Junior Obstetric House Physician; Sparks, E. A., M.R.C.S., L.R.C.P. Lond., Senior Opththalmic House Surgeon; Cavenagh, J. B., M.B., Ch. B. Oxon., Wood, F. G., B.Ch. Cantab., M.R.C.S., L.R.C.P. Lond., Shaw, J. A. P., M.R.C.S., L.R.C.P. Lond., Slaughter, H. L., M.R.C.S., L.R.C.P. Lond., Willey, H. L., M.R.C.S., L.R.C.P. Lond., Tallerman, K. H., M.R.C.S., L.R.C.P. Lond., Burns, C. L. C., M.R.C.S., L.R.C.P. Lond.; Moor, F., M.B., B.Ch. Cantab., Shires, B., M.B., Ch. B. Edin., Rickman, J., M.B., B.Ch. Cantab., Spoor, A. T., M.R.C.S., L.R.C.P. Lond., and Cooke, R. C., M.R.C.S., L.R.C.P. Lond., Clinical Assistants.

Certifying Surgeons under the Factory and Workshop Acts: Everard, W. P., L.R.C.P. & S. Edin. L.R.F.P.S. Glasg. (Athlone); Snowie, R. S., M.B., Ch.B. Aberd. (Burton-on-Trent).

Vacancies.

For further information refer to the advertisement columns.

Bedford County Hospital.—Asst. H.S. £150.

Birmingham General Hospital.—Asst. Obst. Officer.

Birmingham, Queen's Hospital.—Surg. Registrar. £100.

Bootle Borough Hospital.—Sen. H.S. £200. Jun. H.S. £150. Hon. Phys., Hon. Ophth. Surg.

Bristol Education Committee.—Asst. Sch. Med. Officer. £600.

Bristol Royal Infirmary.—H.P., H.S., H.S. to Ear, Nose, and Throat Dept., Cas. O., and Ophth. S. Each £120.

Burnley, Victoria Hospital.—H.S. £200.

Cambridge, Addenbrooke's Hospital.—H.S. £130.

Cardiff, King Edward VII. Hospital.—H.S. £200.

Charing Cross Hospital, Agar-street, W.C.—Phys. in charge of Children's Department.

Derby, Derbyshire Royal Infirmary.—H.S. H.P. Each £200.

Doncaster Royal Infirmary and Dispensary.—Sen. H.S. £225. Jun. H.S. £200.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Asst. Phys.

Eday, Orkney.—M.O. £9 per week.

Evelina Hospital for Children, Southwark, S.E.—H.S. £160.

Exeter City Mental Hospital.—M.O. £300.

Fernhill, Norwich, Ministry of Pensions Hospital and Clinic.—Jun. Res. M.O. £350.

King's College Hospital, Denmark Hill, S.E.—Asst. Radiologist.

Liverpool Royal Southern Hospital.—Two H.P.'s and three H.S.'s. Each £100.

London (Royal Free Hospital) School of Medicine for Women.—Four Part-time Demonstrators in Department of Anatomy.

London Temperance Hospital, Hampstead-road, N.W.—Asst. Res. M.O. £120.

London University.—Professor of Medicine and Director of the Medical Clinic at St. Mary's Hospital Medical School. £2000.

Lucknow University, India.—Prof. of Pathology. Rs.1200 a month. Prof. of Physiology. Rs.1400 a month.

Manchester, Hulme Dispensary, Dale-street, Stretford-road.—Res. M.O. £400.

Manchester Royal Infirmary, Central Branch, Roby-street.—Res. M.O. (female). £200.

Ministry of Pensions, Birmingham Orthopædic Centre.—Jun. Res. M.O. at the Highbury, Uffculme and Sorrento Group of Hospitals. £350 to £400.

Newcastle-on-Tyne, City Hospital for Infectious Diseases, Walkergate.—Res. Med. Asst. £350.

Newcastle-on-Tyne, Hospital for Sick Children.—Jun. Res. M.O. £200.

Newport, Mon., Royal Gwent Hospital.—H.S. £200.

Nottingham Children's Hospital.—Res. H.P. (female). Res. H.S. (female). Each £180.

Oswestry, Shropshire Orthopædic Hospital.—H.S. £250.

Oxford, Radcliffe Infirmary and County Hospital.—Cas. H.S. £200.

Peterborough General Infirmary.—H.S. £200.

Plymouth, Borough of.—Asst. M.O.H. £500.

Preston and County of Lancaster Royal Infirmary.—Sen. H.S. £250.

Prince of Wales's General Hospital, Tottenham, N.—Hon. Asst. P. or S. to X Ray Department.

Royal Eye Hospital, St. George's Circus, Southwark, S.E.—Jun. H.S. £70. Clin. Assts.

Royal Free Hospital, Gray's Inn-road, W.C.—H.S. £50. Hon. Anæsth.

Royal Naval Medical Service.—Surg.-Lieuts. 26*s.* 6*d.* per diem.

Salford Royal Hospital.—H.S. and Cas. H.S. Each £150.

Seamen's Hospital, Albert Dock, Connaught-road, E.—H.S. £150.

Southampton Free Eye Hospital.—H.S. £200.

South London Hospital for Women, South Side, Clapham Common, S.W.—Asst. Pathologist. £150. Anæsth.

South Uist, Parish of.—M.O. and Public Vaccinator. £170.

Stamford, Rutland and General Infirmary.—H.S. £250.

Sunderland Royal Infirmary.—H.P. £200.

Sydney University, New South Wales, Australia.—Lecturer in Veterinary Anatomy and Surgery (including Obstetrics). £500.

Torquay, Torbay Hospital.—H.S. £200.

West London Hospital, Hammersmith-road, W.—Two H. P.'s, H.S. Each £50. P. Neurologist.

Wigan Infirmary.—Jun. H.S. £200. Hon. Asst. Surg.

Worcester County and City Mental Hospital, Powick.—Sen. Asst M O. £500.

The Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Walton-on-Naze.

Births, Marriages, and Deaths.

BIRTHS.

Bigland.—On May 29th, at Rodney-street, Liverpool, the wife of Dr. Douglas Bigland, of a daughter.

Falconer.—On June 2nd, the wife of Dallas S. Falconer, M.B., Ch.B., F.R.C.S., of a son.

Swan.—On June 2nd, at Dartmouth House, West Byfleet, Surrey, the wife of James Swan, M.C., M.B., Ch.B., F.R.C.S., of a daughter.

MARRIAGES.

Greaves—Duggan.—On June 2nd, at St. Luke's, Grayshott, Dr. S. Sowry Greaves, D.S.O., M.C., to Eva Duggan, M.B.E.

Shepherd—Gordon.—On June 2nd, at St. John's Wood Presbyterian Church, London, George A. Shepherd, M.B., Ch.B., Mornington House, Old Southgate, London, to Coral Ogilvie Gordon, M.B., Ch.B.

DEATHS.

Fortescue-Brickdale.—On June 2nd, at Clifton, John Matthew Fortescue-Brickdale, M.D. Oxon., M.R.C.P. Lond., aged 51.

Jupp.—On June 6th, at Chalfont Park Hotel, Gerrards Cross, of pneumonia, Ralph Tennyson Jupp, M.B., F.R.C.S., aged 45 years.

Little.—On May 30th, at Midgham, Berks, Capt. Gerald Lewis Little, M.B., F.R.C.S., I.M.S., retired, aged 37.

Morton.—On May 28th, at Territet, Switzerland, Charles James Morton, M.D. Edin., late of Walthamstow and Welbeck-street.

Skyrme.—On May 28th, Christopher Ralph Skyrme, M.B., B.C., B.A., of Albany-road, Bexhill-on-Sea, in his 49th year.

ALPINISM.*

BY JOSEPH BARCROFT, C.B.E., M.A., F.R.S.

THE effects of rare air upon the human body have always had a peculiar fascination for those who make physiological inquiry their life's work. In spite of all the thought that has been spent on it in the last fifty years, the subject is as full of interest as ever. For this there are several reasons. On the intellectual side it is evident that the knowledge already gleaned has merely served to arouse a deeper interest; on the practical side the effects of rare air, ceasing to be the monopoly of a few mountaineers, have become the limiting factor of the activities of airmen. In this way the air is now vital to the world system of modern transport. Moreover, within the last decade it has become abundantly apparent that many if not all the symptoms of mountain sickness are simply due to some kind of deficiency of oxygen in the arterial blood—a condition also to be found in many pathological conditions. In such the condition of "unsaturation" of the arterial blood is, however, associated with other troubles. If, therefore, we desire to study the effect of this type of oxygen-want for the purpose of applying the knowledge to general pathology, it is best to study it in its least complicated form—namely, where unsaturation of the blood is simply brought about by insufficient pressure of oxygen in the inspired air.

"Oxygen-Want."

The phrase "oxygen-want" requires a word of caution. Oxygen-want in the body may arise from causes other than insufficient oxygen saturation in the arterial blood. It is not, therefore, a foregone conclusion that information gleaned in the high Alps can be applied to general conditions of oxygen-want. Anoxæmia, which by convention means want of oxygen in the tissues, and not merely as its derivation implies—want of oxygen in the blood—may be divided into three classes[1]: (1) the anoxic type, in which the arterial blood is unsaturated; (2) the anæmic type, in which the amount of hæmoglobin per c.cm. of blood is too small; (3) the stagnant or ischæmic type, in which the blood flow is too slow.

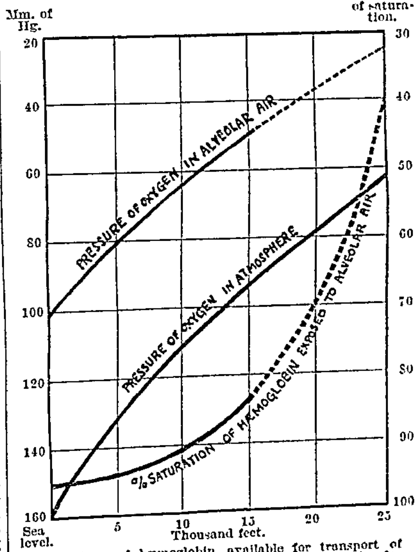
Mountain Sickness.

Mountain sickness is typical of the anoxic type, but not at all typical of the anæmic or of the ischæmic types. Let us pass to the closer study of it. Probably if nine out of every ten persons were asked what they understood by the term "mountain sickness," they would reply that most persons on ascending high mountains, and some on ascending lower ones, vomited. Antiperistalsis is a natural safety valve; but as the study of mountain sickness has proceeded vomiting has held the attention of researchers in a gradually decreasing degree; at present if one were to ask half a dozen physiologists who have worked at over 10,000 feet what they observed, it is probable that not one of the six would mention vomiting as being the first symptom to cross his mind. Yet in point of fact mountaineers who have camped at over 20,000 feet have told me that alimentary trouble is the factor which places the real limit in the altitude attainable. Before discussing the symptoms of mountain sickness in some detail let me first define the cause more particularly than I have yet done.

Cause of Mountain Sickness.

As an ascent is made the barometric pressure gradually diminishes, till at the summer snow line in the Alps (10,000 feet) it is 510 mm., and at the summits of the highest peaks, such as those of Mont Blanc and Monte Rosa (15,000–16,000 feet), the observer is above nearly half the atmosphere and the barometer stands at but 410 mm. As the barometric pressure falls, so in proportion falls the pressure of oxygen which is always approximately one-fifth of the barometric pressure. The figure shows the oxygen pressure in the atmosphere plotted against the altitude in feet. The blood, however, is exposed not directly to the atmosphere, but to the air in the alveoli of the lungs. The composition of this alveolar air cannot be predicted, but measurements have been made up to about 15,000 feet in the Alps with the result shown in the figure. At sea-level, when the atmospheric air forms an oxygen pressure of 160 mm., the oxygen in the alveolar air has a pressure of 100 mm. In other words, the human body, by its configuration, starts with a handicap against it of about 12,000 feet.

To carry the investigation from the alveolar air to the blood which it aerates, one may ask what difference this gradually decreasing-pressure oxygen makes to the blood. That is the kernel of the whole problem of the physiology of alpinism. The lowest line in the figure shows the extent to which the blood would be oxygenated if exposed to the alveolar air of the corresponding altitude at the normal body temperature. At the sea-level 95 per cent. of the hæmoglobin functions and the remaining 5 per cent. leaves the lung without any load of oxygen. As the altitude increases the fall in oxygen pressure produces very little effect upon the amount of oxygen taken up by the arterial blood, but at about 15,000 to 18,000 feet a critical point is reached, and at altitudes above this the blood ceases to function with increasing rapidity, the line separating the hæmoglobin which does not function from that which does. This constantly, and above 18,000 feet rapidly, rising curve of "unsaturation" of the arterial blood is the physiological mountain which the body has to scale, and somewhere on it is the real limit to man's faculties and activities. This curve is the real Everest.



Percentage of hæmoglobin available for transport of oxygen from the lung if the composition of the alveolar air were as shown.

Effects of High Altitudes on the Blood.

Since the blood permeates all the organs of the body the changes which it undergoes may first be studied. Apart altogether from the actual amount of oxygen which the blood carries at any one time, the properties of the fluid as a whole undergo certain well-defined alterations, directed towards the preservation of an approximately constant hydrogen-ion concentration. Our knowledge is limited by the fact that actual measurements of the hydrogen-ion concentration of the blood as it exists in the body have never been made at high altitudes. Hydrogen-ion measurements have been made in chamber experiments both at Copenhagen[2] and on my own blood at Cambridge.[3] These measurements seem to agree in showing that in the chamber there is no change in the reaction of the blood which is large enough to be outside the range of error of the electrode.

---

* Being one of a course of advanced lectures in physiology given in the Physiological Laboratory of St. Bartholomew's Hospital, London.

[1] Barcroft: Presidential address, Section I., of British Association, Cardiff, 1920.

[2] Hasselbach and Lindhard: Zur experimentellen Physiologie des Höhenklimas, Biochem. Zeitschr., 1915, lxviii., 295.

[3] T. R. Parsons, W. Parsons, J. Barcroft: Journal of Physiology, 1919, vol. liii., p. 111.

Measurements before incarceration and after six days in my case were for the reduced arterial blood pH = –7·35 and –7·36 respectively. Such constancy of reaction is far from a matter of course. For it is maintained in spite of one factor at all events which would tend to disturb it greatly—namely, a marked fall in the concentration of free carbonic acid in the blood. To compensate for the loss of free CO_2, which would tend to make the blood more alkaline, the kidney secretes alkali and so preserves the balance. In this presentation of the subject I have, as it were, stopped the film to show the most striking picture. The ends of the film are much less definite and extremely difficult of interpretation. especially as regards what is cause and what is effect; for the moment we will leave the matter here.

The constancy in the reaction of the blood seems to carry with it one very important functional property of the blood—namely, a constancy of the power of the hæmoglobin to unite with oxygen. So far then as the resting body at high altitudes is concerned, the blood preserves its normal power of acquiring oxygen in the lung and of giving it over to the tissues.[4] During muscular exercise, however, the reaction of the blood is not constant either at low or on high mountains[3 5 6]. The blood becomes more acid, and in two words the effect of altitude is that a much less amount of exercise will produce the same change in reaction at altitudes than at low, therefore every derangement due to exercise appears with correspondingly greater facility at high altitudes. The following data from a chamber experiment illustrate this point:—

—	In atmospheric air.	In chamber.
Quantity of exercise in 36 mins.	4600 foot pounds.	2700 foot pounds.
Pressure of oxygen—		
In air	87 mm.	160 mm.
In arterial blood ..	48 mm.	100 mm.
Exponent of hydrogen-ion concentration of blood during rest	7·43	7·44
Ditto at end of exercise	7·35	7·36
Difference	0·08	0·08

Analysis of the blood on Monte Rosa and elsewhere seemed to show that the increase in acid is due principally to the formation of lactic acid by the muscles.

The Heart.

It is notorious that life under anoxæmic conditions puts a strain upon the heart. Any considerable amount of exercise causes evident palpitation, and here I would remind you again that at high altitudes no one does take any considerable quantity of exercise. But even at rest there is usually some quickening of the pulse; not only is this quickening the direct result of oxygen-want, but the suddenness with which it is abolished by administration of oxygen is dramatic. If I may refer again to the experiment in my chamber a year ago, I would draw your attention to an occurrence which illustrates my point. One night, the fourth of my incarceration, I was lying wakefully in bed and counting my pulse from time to time; quite regularly it was within a beat or so of 86. The time was 2 A.M. For a few moments I left the chamber and went into the outer air. In less than a minute it had dropped to 58—a normal figure for me at that time—and even mild exercise on the bicycle ergometer did not greatly raise it. It is evident, therefore, that the heart itself was not in an abnormal state, and—apart from the anoxæmic conditions under which it was working—not unduly irritable.

Let us now turn to consider what the strain on the heart means. How are we to estimate "what the heart is doing"? I use this phrase advisedly, because I wish to avoid the phrase "work done by the heart," which has a definite physiological significance that I do not wish to convey. "The work done by the heart," or at least by the left ventricle, means approximately the volume of blood put out and the mean pressure at which it leaves the ventricle. This may be no indication of the strain put upon the heart. I will give you a case in point.

Just now I have a pupil who suffers from paroxysmal tachycardia.[7] His heart suddenly commences to beat at about 200, and continues so to do for about eight hours. The quantity of blood which leaves the heart drops from 8 to 3 litres per minute, and as the arterial pressure is not greatly altered, the work done by the left ventricle would drop in the same proportion. Yet, of course, it is inconceivable that the man's heart is in reality having a rest. We must seek some other numerical estimate of the strain which the heart is sustaining. In this connexion I would refer you to the work of Rohde.

Rohde,[8] working on the perfused heart, came to the conclusion that the oxygen used by the heart, which may perhaps be taken as a measure of the energy which it is transforming, varied with the product of the pulse-rate × the maximal pressure at each beat. Since Rohde's time the subject has moved rapidly, and all the beautiful work on the metabolism of the heart which we associate with the heart-lung preparation[9] has been carried out. Yet the simplicity of Rohde's result gives it a value which still remains, because the elements from which he builds his measure of "what the heart is doing" are such as can be estimated—the pulse and the systolic pressure. If we apply Rohde's test to the case of paroxysmal tachycardia to which I have referred a result appears quite opposite to that given by conventional measurement of the "work." The pulse in this person, normally 80, with a systolic pressure of 120 mm., rises to 200 with a systolic pressure of 100 mm. Therefore there is reason to suppose that the metabolism of his heart during the attack is increased in some such ratio as 20,000 to 9600, while the amount of blood which it distributes is less than halved.

If we apply the same reasoning to the figures which I gave for my experiment in the chamber. the pulse, as I said, dropped from 86 under anoxæmic conditions to 58 outside the chamber, the arterial pressure was 105 in the chamber, while it normally is 110, so that the limiting figure for the product of the arterial pressure and the pulse was:—

In the chamber in oxygen .. .. $86 \times 105 = 9030$
Outside the chamber in 21 per cent. oxygen .. .. $58 \times 110 = 6380$

The above figures are, of course, only approximations, because the data used are the mean arterial pressures, and not, as they should be, the systolic pressures. Nevertheless, as approximations they illustrate the point that the heart is doing more than is normally the case during rest.

A natural inquiry arises as to what is driving the heart to its unusual exertions. The answer is. I think, the "nervous system." Dr. W. E. Dixon and I have taken many tracings in years gone by of perfused mammalian hearts which had been excised from the body and to which the supply of oxygen was gradually reduced. In no case did we observe a quickening as the result. Whether the anoxæmia causes a stimulation of the sympathetic or a diminution of the vagus tone, or both, is as yet uncertain. In the absence of any direct proof that the C.N.S. is stimulated by diminished pressure of oxygen in the blood, one rather leans to the idea that the vagus control is to some extent withdrawn. It is natural to see in this increased activity of the heart some sort of compensation to the body for the anoxic condition of the blood. One might suppose that by the supply of an increased volume of blood per minute the body might get the quantity of oxygen which it required, but we have no knowledge that such is the case. So far as man is concerned the data are lacking; such observations as exist were made on the cat by Doi,[10] who found no increase in the volume of blood driven round the body when diminished pressure of oxygen in the inspired air led to a quickening of the pulse.

I have dwelt on the heart at rest because, little as we know about the effect of anoxæmia upon it, that little is at least more than we know about its effect on the heart during exercise. Yet, of course, the fact about the heart which impresses itself upon the mountaineer is not increased pulse-rate at rest, but the increase in the pulse-rate caused by a very trifling degree of exertion. Dr. J. S. Haldane once put this point very pithily to me; he said: "Over 10,000 feet everybody is a case of disordered action of the heart."

In view of the amount of work which has been done within the last five years on disordered action of the heart and on effort syndrome, it is much to be hoped that the investigations of mountain-climbers in this direction may early bear considerable fruit. In the meantime let me pass from the vascular system to its partner in the effort syndrome—the respiratory system. Just as there is usually some quickening of the heart at high altitudes, so there is usually some increase in the total ventilation even at rest.

Respiration.

More light is necessary on the cause of the mechanism by which the increase in the volume of air which enters and leaves the chest is brought about. There are two theories on the subject, for each of which there is something to be said, and which indeed are not at all mutually destructive. The first is based on two ideas largely accepted as the result of work by Haldane and Priestley,[11] (1) that increased total ventilation is a function of increased hydrogen-ion concentration of the blood; (2) that the increase of hydrogen-ion concentration is necessary to produce a perceptible increase in total ventilation is very slight. The second theory is that the hydrogen-ion concentration of the blood which reaches the respiratory centre is precisely the same at high altitudes as at low ones; but that in view of the fact that the arterial blood contains somewhat less oxygen than usual, the respiratory centre is more active. The actual evidence on which a decision could be based as to which of these two theories is correct is very meagre.

The theoretical questions at issue are: (1) is the hydrogen-ion concentration of the blood altered (with that we have already dealt) and (2) does the degree of anoxæmia experienced in the Alps alter the respiratory rhythm?

The following data may be quoted on this subject from my chamber experiment, some of which have already been discussed. A measured quantity of work was carried out on the bicycle ergometer (*a*) in normal air, (*b*) at the end of six days of progressively anoxæmic conditions; the increase of hydrogen-ion concentration of the blood and the total ventilation were observed.

—	Work performed.	Increased hydrogen-ion concentration of blood.	Increased total ventilation.
Under normal conditions	4600 foot pounds	7·43—7·35 = 0·08	29·2—8 2 = 21 litres.
Under anoxæmic conditions	2700 foot pounds.	7·44—7·36 = 0·08	32·2—6·1 = 26 litres.

The figures show that in each case there was the same increase in hydrogen-ion concentration of the blood and almost the same increase in the total ventilation, so that they afford little help to the theory that the anoxæmic conditions had rendered the centre unduly irritable. On the other hand, they show that this increase in the hydrogen-ion concentration of the blood had under anoxæmic conditions resulted from little more than half the effort that had been required to produce it in atmospheric air. This single experiment, and as far as I know it is the only one available, would appear to favour the idea that the acidæmia factor in effort syndrome is exaggerated at high altitudes, and that there is little change in the irritability of the respiratory centre. While the above experiment gives little support to the theory of increased irritability of the respiratory centre as the result of oxygen-want, it also sheds no light on the alternative theory that the increased ventilation at rest is due to increased hydrogen-ion concentration of the blood. In the experiment in question there was no increase in total ventilation during rest.

Skeletal Muscle.

First, then, let us consider the musculature. In connexion with the muscles of the body the effect of oxygen-want, which is to me most interesting at the present time, is not much stressed by climbers—namely, undue stiffness.

It forced itself first upon me, not in the Alps, but in my own respiration chamber, when sojourning there about 15 months ago. It was my custom to pass some portion of the afternoon taking muscular exercise in the form of riding the bicycle ergometer. The result of this exercise was to make me very stiff. Quite recently, however, the same phenomenon occurred in a much more telling way. Three subjects were testing their capacity to do mental work in an atmosphere which was poor in oxygen, to which they were quite unacclimatised. In one case I suggested to Dr. J. P. Lawson, of the Cambridge Psychological Department, who was carrying out the research, that they should undertake physical exercise previous to the mental tests. This they did in the shape of Swedish drill, with the unlooked-for result that they suffered acutely from stiffness, which was very definite for three days, and only disappeared entirely at the end of a week. Dr. Lawson describes the degree of stiffness in his own case as having been exceeded on the previous occasion—namely, when entirely out of training he ran eight miles without a stop on a club run. In control experiment, in which the same drill was undertaken in air after the lapse of about three months, the same subjects experienced in one case no stiffness, in two others stiffness of a quite inferior order. No doubt the less the anoxæmia the greater the amount of exercise which can be taken without subsequently paying the penalty of stiffness. Until trained, muscle, whether because it needs less oxygen or because it is supplied with more, can take almost as much exercise in normal conditions as it is capable of. Such, then, is the subjective effect of oxygen-want on muscular exercise. The principal objective effect which has been discovered is the excessive amount of lactic acid which appears in the blood.[5] The possible relation between the subjective stiffness thus observed, the objective changes in turgidity, and the properties of muscle proteins which are known to occur in muscle when stimulated under grossly anoxæmic conditions form an interesting subject.

Effects of High Altitude upon the Mind.

These effects are perhaps the most interesting of the whole series. It is a wonderful thing to see a man's whole character change as the result of exposure to a certain degree of rarity of the atmosphere, and I am sorry to say this change is always for the worse. Usually some want of restraint occurs which takes different forms in different individuals, the best tempered men may become testy, the most equible may become hilarious. I am sorry to say I have yet to meet the man who becomes pleasanter to live with when he is at 12,000 feet altitude than at the sea-level. These traits may pass into that apathy which is well known to beset climbers, and of which I could give many instances. These traits suggest some sort of intoxication, but such dependence of character on environment brings one into a much wider sphere than that of experimental physiology which limits the scope of this paper.

NATIONAL CHILDREN ADOPTION ASSOCIATION.

THIS voluntary organisation was founded by Miss Clara Andrew with the primary object of assisting children orphaned or rendered destitute by the war. Its aims were subsequently extended, and now include the formation of a National Register of those who are willing and able to guarantee the future welfare of some needy child, and of a similar register of children accepted by the committee as suitable for adoption. No premiums or weekly payments are allowed to adopters of children, and the interests of both parties are further guaranteed by references, doctors' certificates, and interviews as considered necessary. It is hoped that several hostels will shortly be established in connexion with the association; one hostel at Tower Cressy, Campden Hill, W., has been open since December, 1919, and others have since been opened in London and Southampton. The address of the association is 19, Sloane-street, London, S.W.; subscriptions should be sent to the treasurer, National Children Adoption Association (Francis O. Rybot, Esq.), c/o London Joint City and Midand Bank, 419, Strand, London, W.C. 2.

MALINGERING AND SIMULATION.

IN a paper contributed to the *Military Surgeon* for May Dr. Tom A. Williams deals with Malingering and Simulation of Disease in Warfare, contrasting thetwo extreme views held in the army about malingering; the first that all complaints by the soldier not easily intelligible by the medical officer are feigned and to be punished, the other that all detected simulations are the result of mental abnormality and are to be treated accordingly. His own view is that malingering is the outcome of a selfish desire for greater comfort than the environment supplies, a desire to be fought by moral stimulus, and by the fear of punishment which will make the already uncomfortable environment still more inconvenient. He notes in France and the United States a tendency to relieve simulators of responsibility, but thinks that in England borderland criminals are apt to be punished unless conspicuously insane. Malingering and the exaggeration of symptoms do not occur in simple severe injuries requiring amputations, but in slighter and less definite injuries, especially concussion cases without external wounds; that is why relatives and nurses must be warned not to keep awake the patient's memories of past horrors, nor to dwell on his future uncertainties. The malingerer has really a very bad time; he must be constantly on the alert to see his story is being in no way discredited, and that anxiety wears him down and he loses colour and weight, and people think this proves him ill. Such cases do become nervous and afraid of detection, and are ready to recover if some new and striking treatment gives them an excuse. One patient who had been for eight months a deaf-mute indicated one afternoon that he expected to recover. He went out for a walk, and the evening paper announced he had had a fit in a public place and on coming to himself gave out to his kindly helpers that he had recovered, thank goodness; later he wrote a letter to the doctor, thanking him for saving him from court martial, and promising to do all he could to atone for his conduct.

BRIGHTON AND THE BLIND.

THE Brighton Town Council has just adopted a scheme for the exercise of the powers conferred on the council under the Blind Persons Act, 1920, and has voted a grant of £100 to the local Blind Relief and Visiting Society. The object of the scheme is to keep in touch with babies born blind or with defective sight, and in the case where the home is unsuitable and where the infant shows signs of not developing there is provision for the infant being sent to the National Institute's Home for Blind Babies. Provision is also made for children of school age, for the teaching of basket-making, chair-caning, &c. after school days, and for the marketing of goods.

AN EXAGGERATED REPORT.

OUR Geneva Correspondent writes: Although a good deal of excitement has been aroused over an incident in the surgical clinic here, no rumour current is quite so startling as that found in the English press that "the surgeon . . . extracted the beating heart of a man lying unconscious on the operating-table." The patient in question was a suicide who had inflicted on himself an incised wound. The knife had penetrated the heart and diaphragm. The thorax was opened with the idea of suturing the heart muscle, but the man was already dead. It is said that one of the assistants saw a fibrillation or contraction after adrenalin had been injected into the heart. The fact that the surgeon proceeded to open the abdomen seems to be criticised both on the ground that the patient was dead and therefore that no further procedure was proper in the operating-room, and on the ground that as a contraction of the heart had been seen the patient was not beyond hope of recovery, and therefore exploration of the abdominal cavity was unjustified. A competent commission is investigating these and similar charges and will report in due course In the meantime it should be undtrstood that the dispute is rather on a question of technique than on a question of honour, and that whatever the result of the present inquiry no gross impropriety can be charged to the surgeon.

CONJOINT BOARD OF SCIENTIFIC SOCIETIES.

THE fourth report of this Board shows that scientific investigation is being seriously hampered by the heavy cost involved in the publication of results. An unusually large number of papers are being communicated, including many held up during the war, while the resources of the societies are insufficient at present prices to publish even the normal pre-war number. The country is thus in danger of being handicapped at a time when the rehabilitation of industry is in serious need of scientific assistance. A short abstract of the third report of the Committee on the Water Power of the Empire is included in the report of the Board. It is claimed that too little is being done to ascertain the total resources available, or to secure uniformity in investigation and record. It is urged that steps should be taken to convene an Imperial Water Power Conference in London at which the various Dominions and Dependencies of the Empire should be represented. Such a conference might result in the creation of an Imperial Water Power Board with extensive powers to carry out a comprehensive policy for stimulating, coördinating, and where necessary assisting, development throughout the Empire.

The Conjoint Board of Scientific Societies has also dealt with questions relating to the formation of National Research Committees in connexion with the International Research Council formed in 1919; with the collection of scientific data in the former German Colonies; and with instruction in Technical Optics. The research on glues and other adhesives initiated by the Board as a war measure, at the instance of the Air Ministry, has now been taken over by the Department of Scientific and Industrial Research.

EUGENICS EDUCATION SOCIETY.

IN his address at the annual meeting of the Eugenics Education Society on June 7th Major Leonard Darwin said that eugenics had been called a dismal science, it should rather be described as an untried policy. If combined with an equal striving for improvements in human surroundings, it would more truly justify a hopeful outlook than anything ever yet tried. Both in genetics and eugenics further advances in knowledge are much needed, and many inquiries are now only held up for want of funds. The wisdom of attending to breed in the case of cattle and dogs is universally admitted. Experiences in the stockyard enabled us better to understand the laws of natural inheritance, but reliance on those laws does not imply that the methods of the animal breeder should be introduced into human society. Eugenists advocated nothing which was contrary to the highest religious ideals. They had been accused of wishing to abolish love as a guide to conduct; but this was false. They wished to purify it of all harmful influences. Love was largely aroused by advantageous moral and mental qualities, and it formed the firmest foundation on which to base a eugenic policy. By promoting right ways of regarding sexual problems the moralist was often unknown to himself striving to improve the racial qualities of future generations. We should encourage the discussion of all relevant reforms, but should be cautious in recommending governmental interference. If action be too bold, progress will be slow, for the wrong road will often be taken. If discussion be not bold, progress will also be slow; for a nation cannot grope its way quickly in the darkness of ignorance. As to sterilisation, for example, by open discussion true conclusions would be most likely to be reached. Nearly every subject should be discussed, the occasion being properly chosen. Politicians mainly settle how far the teaching of science is to affect legislation, and this they do largely to catch votes. But the votes of future generations cannot now be caught, and their interests will receive scant attention in all democratic countries. Eugenists should discuss long and freely, and when they do advance, advance boldly. Eugenics aims at increasing the rate of multiplication of stocks above the average, and at decreasing that rate in the case of inferior stocks. Eugenists put moral qualities first, mental second, and physical last. When science taught us that man had been slowly evolved from some ape-like progenitor, it gave rise to a new hope that that upward march would be continued, and out of that hope sprang the eugenic ideal. But science, whilst giving good grounds for hopes, also issued a grave warning concerning the danger of national deterioration from the unchecked multiplication of inferior types. A determination that such a downfall shall not be the fate of our nation if we can help it is a sentiment felt by all of us who are inspired by the eugenic ideal.

SHOT BEFORE BIRTH.

FROM Guatemala, where the use of firearms is more free than in the equable English climate, there comes a curious story of how a baby was shot before birth and probably saved her mother's life at the expense of a slight flesh wound only. Dr. Joaquin Barnoyag, who relates the story[1] was a good deal puzzled by the case. His patient, aged 24, had certainly a small round wound two fingers'-breadth above the umbilicus. But there were no serious symptoms, nor even was there any pain. Although the woman was only eight months pregnant, labour began on the night of her admission into hospital and a healthy girl was born. It was not till two days later that the doctor was asked to see a suppurating fistula on the baby's left buttock. He probed but could find no metal. Clearly the bullet had entered the uterus—but what had happened afterwards? The X rays failed to discover it in mother or child. The mother's clothing showed only one hole. Completely mystified, Dr. Barnoyag asked the mother herself what had happened to the bullet and she at once admitted that she had found one in her bedclothes shortly after the baby was born. If there had been no pregnant uterus to catch the missile no doubt the intestines would have been perforated and the woman would very possibly have died either from hæmorrhage or from peritonitis.

INTRATRACHEAL INSUFFLATION OF CHLOROFORM: A SIMPLE METHOD.

MR. G. F. V. Anson, M.R.C.S., L.R.C.P. Lond., late senior anæsthetist to the Children's Hospital, Birmingham, and assistant anæsthetist to the General Hospital in that city, who is now on his way to New Zealand, where he intends to continue his studies, writes as follows:—

"I venture to bring to the notice of the medical profession a method of giving an intratracheal insufflation of chloroform vapour. I have used the method a number of times, and have found it eminently satisfactory. The patient is anæsthetised by the usual methods, and an intratracheal catheter is passed through either the mouth or the nose. The catheter is connected by rubber tubing to a mercury safety-valve (such as is fitted to all intratracheal apparatus), and this, in turn, to an oxygen cylinder, from which a slow stream of oxygen is allowed to flow. Into the delivery tube of a Junker apparatus is then fitted a large hypodermic needle of about the bore used with a Barker spinal anæsthetic syringe. This needle is afterwards passed into the lumen of the rubber tube near where it joins the intratracheal catheter. By squeezing the bulb of the Junker apparatus a slow stream of chloroform vapour is allowed to mix with the oxygen. The rate of delivery of the chloroform vapour is curtailed to within safe limits by the bore of the needle.

"The method is of considerable use in such operations as diathermy of growths in the mouth and pharynx where, of course, the use of ether is contra-indicated."

The Relation
OF
HEART DISEASE AND PREGNANCY.

BY SIR JAMES MACKENZIE, M.D. EDIN., F.R.S.,
DIRECTOR OF ST. ANDREWS CLINICAL INSTITUTE.

IN FOUR SECTIONS—SECTION III.

MURMURS.

Misconception of the Significance of Murmurs.

I RECOGNISE at the outset that in dealing with murmurs I have to overcome a great number of erroneous notions held by the medical profession with conviction. The idea that a perfectly sound heart may show a murmur is so surprising to many doctors that they cannot accept it. Their view seems to be that if murmurs are not organic they are functional and imply debility or some other condition of weakness. That a murmur may be as physiological as a pure sound is altogether outside the limits of this faith. I know that some doctors are ready to admit that some murmurs may be without significance; but nowhere have I found a description which makes clear the exact difference between murmurs of serious significance and those which are innocent. It is on this ground that teachers have failed to enlighten their students. They hedge so much in their descriptions that their pupils go forth with vague ideas and consider it wiser and safer when in practice to view all murmurs with suspicion. I speak of this from a wide experience derived not only by seeing individuals to whose murmurs an unnecessarily grave significance has been attached, but also by questioning doctors as to their views.

In no field of medicine, so far as I know, has this attitude towards murmurs proved so disastrous as in pregnancy. The detection of an innocent murmur has often supplied a reason for forbidding pregnancy or even marriage. Indeed, when I ponder on this subject I am sometimes inclined to think that the discovery of auscultation has actually done more harm than good to the practice of medicine.

It is necessary, if we are to make any progress at all, to understand wherein lies the danger associated with murmurs. Most murmurs seem to arise at the valve orifices of the heart. It has been demonstrated that certain damaged valves give rise to abnormal sounds, and it is evident from the appearance of the valves post mortem that the flow of blood must have been hindered on passing through the orifice or that the valves, being incompetent, have allowed blood to escape backwards. In this way the work of the heart muscle has been hampered. An additional burden being thus thrown upon his heart, a man leading his usual life puts a greater strain on this organ than it is fit to bear. Thus it is only a matter of time until the muscle becomes exhausted and heart failure sets in. But there are murmurs which do not indicate damaged valves, or valves damaged to such a degree as to cause embarrassment to the heart, and it is necessary to distinguish between these murmurs and those which indicate valve damage which embarrasses the heart.

Physiological Murmurs.

Physiological murmurs are always systolic in time, and it is impossible to tell the origin of the greater number of them. They may be loudest at the apex or at the base, or at mid-sternum; they may vary with respiration or posture; sometimes they are heard when the patient is lying and disappear when he stands up; again, they may be present on standing and disappear on lying down. Much time has been spent in speculation on their causes, and fanciful names have been bestowed upon them. From the point of view of the heart's efficiency they are negligible. They indicate neither disease nor impairment, and do not foreshadow the oncoming of any heart trouble. I make this statement as wide a one as possible, for I have watched great numbers of people at all ages—the young growing into manhood and womanhood, leading strenuous lives, and in the case of the women bearing children—*yet in no case have I seen any harm result from the* fact that their doctor ignored these systolic murmurs. Moreover, there is not to be found in the whole literature of medicine, so far as I am aware—and I have diligently sought for such evidence—a record of a single case of an individual, man or woman, who suffered from heart failure of which a systolic murmur was the only symptom.

Functional Murmurs.

Functional murmurs are usually assumed to be due to dilatation of the heart; the orifices of the valves are supposed to be rendered so wide that the valves fail to close them. This is not entirely correct, for while it is true that we may find a murmur with dilatation of the heart, we may often find great dilatation without a murmur. Further, murmurs come and go when there is no perceptible change in the size of the heart; they may, for example, appear only when the organ is excited or when the patient stands up, and may disappear when the heart quiets down or the individual is at rest. Again, murmurs which we find when the heart is acting quietly, with the body at rest, may disappear on exertion or excitement.

From this it can be inferred that there is some special mechanism, apart from that involved in the dilatation of auricle and ventricle as a whole, which is capable of producing a murmur. This obscure mechanism varies in its efficiency according to circumstances which we are still unable to appreciate. The importance of this is most clearly seen in connexion with the hearts of young people, in whom it is probable that the organ has a peculiar power, which is gradually lost in later life, of adapting itself. It must be remembered also that free regurgitation can take place at the mitral and tricuspid orifices without producing any murmurs. We frequently get evidence of marked tricuspid regurgitation in the veins of the neck and in the liver, yet cannot detect a tricuspid murmur when we come to listen to the patient's heart.

Systolic Murmurs and Heart Failure.

These systolic murmurs, whether functional or organic, are thus supposed to be originated by an escape of blood back from the contracting chamber. This is called regurgitation and has, as we have seen, been assumed to be the chief factor in the production of heart failure. From the theoretical study of it has arisen the "back-pressure" view of heart failure.

There are, however, no accurate data regarding the quantity of regurgitant blood necessary to produce a murmur; and so we are forced to estimate this amount by indirect methods. I have been able to keep under observation, for 20 or 30 years, individuals with loud, rasping, systolic, mitral murmurs, who gave a history of rheumatic fever, and so permitted me to conclude that the murmurs were due to some damage of the mitral valves. These patients never suffered from heart failure. I venture, therefore, the conclusion that, in them, the leak at the valve was small and the damage slight. One may thus say that within certain limits, and in respect of mitral murmurs due to damaged valves, the smaller the leak the louder will be the murmur. In the case of functional murmurs, the leak, if there be a leak, is so slight that it never, except in cases where there exists grave damage to the heart muscle, embarrasses the auricles in their work. The small quantity of blood thrown back does not alter appreciably the size of the auricles, for we often find murmurs in hearts of the normal size.

Differentiation of Functional from Organic Murmurs.

It is not always easy to distinguish between functional and organic murmurs. As a rule functional murmurs are systolic in time and are heard with equal clearness over different parts of the heart. They are usually soft and blowing. But these characteristics do not distinguish them from some organic murmurs. Indeed, though much has been written, and though many attempts at exact differentiation have been made, it remains true that even the most seemingly characteristic organic murmurs resemble functional murmurs so closely that it is not possible in all cases to arrive at certainty. A very rough murmur, especially if accompanied by a purring tremor or a musical note, is indicative of a valve lesion. In the early stages of an endocarditis, however, the murmur is usually soft and blowing, and so presents "functional" characteristics.

To distinguish between these two murmurs the whole circumstances of the case must be considered. In the first place, it is necessary to bear in mind that a murmur may be a normal event. When we find a systolic murmur occurring in an individual in robust health who reveals no other cardiac sign, such as a thrill or an increase in the size of the heart, we may consider the murmur as indicative neither of impairment nor of disease. When we find a murmur occurring in a debilitated person, we should avoid arriving at any conclusion until a search has been made for conditions which may account for the debility. Examples of such conditions are anæmia, imperfect nourishment, insufficient rest, and disease of other organs. It is of great importance, too, to place in their true perspective murmurs occurring in febrile cases, or after the subsidence of an acute febrile attack such as rheumatic fever. The question in these instances is whether the heart has been affected by the disease process. It is always necessary to bear in mind that the raised temperature or the toxins of the illness may produce changes in the heart's action as opposed to changes in its structure, and so may give rise to murmurs and even dilatation which have no organic basis in the strict sense. During the febrile stage of an acute illness, therefore, judgment should be suspended. It should remain in suspense until definite signs of an organic lesion are forthcoming. After a febrile attack a murmur which has arisen during the attack may be observed to persist, or again a murmur may arise at this time de novo. In these cases the other signs and symptoms present must be observed and weighed duly before conclusions are reached. Thus if, after the subsidence of the fever, the rate of the heart becomes slow and the respiratory type of irregularity develops, it may be assumed that the heart has escaped infection and that the murmur is functional. If, on the other hand, the rate is persistently increased, fear may be justified that the heart has become infected, and that active changes are going on.

Significance of Systolic Murmurs.

Since it is true that individuals with systolic murmurs may be in perfect health, may be leading strenuous lives, and may never show any sign of heart failure, we are entitled to conclude that these murmurs may be a physiological and normal sign, and indicate no impairment of the organ's efficiency, nor foreshadow the oncoming of its failure.

I wish to insist upon this, and I base my insistence on the fact which I have already stated, that I have watched numbers of healthy young people, who exhibited such murmurs, grow up into manhood and womanhood, lead healthy and vigorous lives, and never show the slightest sign of heart failure. We know so little of the causation of murmurs that we have small justification indeed for treating them as abnormalities. Even if they are due to regurgitation, it is quite conceivable that this regurgitation may be consistent with a good functioning heart. I have already pointed out that the fear of regurgitation has attained the dimensions of a bogy in the medical mind; further, I have pointed out that, even in cases of organic disease, the amount of regurgitation necessary to produce a murmur is probably very slight. Again, functional murmurs may be present in debilitated individuals; in these cases the murmur is not necessarily an indication of disease or impairment of the heart. Nor is the valve incompetency which its presence indicates the cause of the debility. Manifestly, a murmur is thus but one of many symptoms which an individual may exhibit. Sound diagnosis demands therefore a search for other evidences and signs which may throw light on the fundamental cause of the debility. I do not deny, in saying this, that a systolic murmur may be present in cases of grave heart failure, but I do urge that in these, as in all other cases, it is but an associated symptom. The valvular incompetence is not the cause of the heart failure; it is merely one of the changes which have arisen in consequence of impaired functional efficiency of the heart muscle.

Significance of Organic Murmurs.

I feel that I cannot emphasise this truth sufficiently. That organic murmurs have a varied significance is true, and that they are associated with heart failure is not in dispute; I am nevertheless convinced that the valve lesions which they indicate are in most instances not the cause of the failure. We cannot afford to forget in this respect that individuals with murmurs due to damaged valves caused by some infective disease, such as rheumatic fever, may lead vigorous lives, and in strenuous occupations, without any sign of heart failure.

We conclude, then, that valve lesions in themselves may not necessarily be of serious significance. As, however, murmurs are often associated with heart failure, the presence of organic murmurs would give rise in our minds to the following considerations:

(1) Whether we have here an indication that the heart has been invaded by a disease process;

(2) Whether the damage done by the disease process is stationary or is slowly progressive;

(3) Whether the disease process has affected and impaired the heart muscle as well as the endocardium; and

(4) Whether the damage to the valve is such that it obstructs the work of the heart and so embarrasses the muscle and impairs its efficiency.

In acute illnesses, as we have suggested, it will not be possible to answer these questions, for there the immediate consideration is the infection itself. In chronic cases—that is to say, cases described as chronic valvular disease—it is absolutely necessary that these questions should be considered and answered if a rational conclusion is to be reached. The method of obtaining the knowledge necessary to answer them will be described in connexion with the different valve lesions.

To sum up: estimation of the significance of murmurs, as of all other signs, should be based not on the murmur itself, but on the functional efficiency of the heart, and on the presence or absence of additional symptoms of cardiac mischief (size, rate, and rhythm). If we find in a heart of normal size and rhythm (or with the respiratory type of irregularity) a systolic murmur unaccompanied by evidence of cardiac inefficiency, we may conclude that this heart is perfectly sound. If there be present evidence of weakness, or of other abnormal conditions, then the opinion we reach should be based on these conditions, and not on the murmur.

MITRAL REGURGITATION.

Nature of the Valve Changes and Character of the Murmur.

Mitral regurgitation may be the result of a damaged valve, or of dilatation of the auriculo-ventricular orifice from the giving way of the muscles supporting the valve. The murmur of mitral regurgitation is systolic in time; it is loudest at the apex. It may be soft and blowing and of little intensity. Sometimes in these cases it is heard over a very limited area; in other instances it is propagated into the axilla; again, it may be rough and loud, and may be heard over the whole heart and round at the back of the chest. It is not always possible to tell whether this murmur is due to dilatation of the auriculo-ventricular orifice or to damage of the valve. The rough, loud type, with an accompanying thrill, is always a sign of a damaged valve.

Mitral Regurgitation and Failure of Heart Muscle.

When the muscle of the heart is unimpaired, little or no bad effect follows incompetence of the mitral valve. Even in those cases in which the regurgitation is due to "functional" dilatation of the orifice, the contractile power of the muscle may maintain a good and efficient circulation and the patients enjoy perfect health. The really serious trouble in connection with mitral regurgitation arises when the myocardium is damaged; the regurgitation may then add to the embarrassment. Yet it should be remembered that until the muscle actually gives way few symptoms of heart failure may be produced.

Dilatation is generally looked upon as the result of mitral regurgitation, the idea being that back-pressure ultimately causes the walls of the right heart to yield. This is not quite correct, for long before there is any back-pressure we may find evidence of a dilated right heart. Thus, if during one of the slight attacks of heart failure which are likely to occur after over-exertion we investigate the condition of a heart—in which the valves have been damaged by rheumatic endocarditis—we may find the organ slightly dilated, the right ventricle in front and the left ventricle pushed to the left, behind the lung. The apex beat in such a case is caused by the right ventricle, as is shown by the occurrence of an indrawing of the beat during systole. After a few days' rest and treatment, this right heart may retreat; the apex beat will then be caused by the left ventricle, and the beat will present the normal character, i.e. an out-thrust during systole (see Fig. 3). In these cases there is no evidence of pulmonary engorgement and back-pressure.

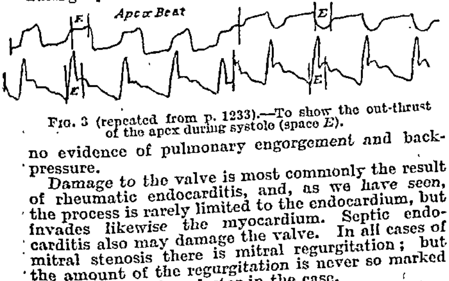

FIG. 3 (repeated from p. 1233).—To show the out-thrust of the apex during systole (space *E*).

Damage to the valve is most commonly the result of rheumatic endocarditis, and, as we have seen, the process is rarely limited to the endocardium, but invades likewise the myocardium. Septic endocarditis also may damage the valve. In all cases of mitral stenosis there is mitral regurgitation; but the amount of the regurgitation is never so marked as to be the serious factor in the case.

Regurgitation occurs through a mitral orifice, of which the valve is uninjured, in the later stages of many affections—for example, conditions which produce exhaustion of the heart muscle and more especially renal disease and cardiosclerosis. Here the mischief is brought about by the failure of the muscle to support the orifice; regurgitation may in such cases furnish one sign of a final and fatal exhaustion of the heart muscle.

It will thus be seen that the symptoms produced by mitral incompetence are only grave when there is also muscle failure. In this latter event we shall encounter those symptoms of heart failure in general which we have already discussed, and the earliest of which is usually breathlessness on exertion. When dropsy sets in, auricular fibrillation (q.v.) is commonly present.

Mitral Regurgitation with Auricular Fibrillation.

The necessity of assessing the significance of mitral regurgitation in terms of the presence of signs of damage to the muscle becomes very evident when we examine the literature of this subject and note how great is the confusion of mind which inevitably results from an imperfect understanding of the nature of symptoms.

Angus Macdonald, in his book, quotes the cases of two women with mitral insufficiency who passed safely through repeated pregnancies (Cases XV. and XVI.). He then quotes the cases of two other women (XVIII. and XIX.) with mitral insufficiency who died from heart failure shortly after delivery. The one sign common to these four cases was a mitral systolic murmur. When, however, the other recorded signs are studied, a striking difference between the two groups is found. In the first group —those who did well—the response to effort was good; in the second—those who died—breathlessness on effort was noted and is clearly described. In one of those who died (Case XIX.), the pulse was "rapid and irregular," an almost sure indication that the patient suffered from auricular fibrillation—a matter of far more importance than the murmur. The post-mortem examination showed not only a damaged mitral valve, but a damaged myocardium.

Mitral Regurgitation and Pregnancy.

The detection of a mitral systolic murmur in a woman who is pregnant or who may become pregnant should cause the physician to consider the following *points*:

(1) The response to effort;
(2) The size of the heart;
(3) The rhythm of the heart.

If the response to effort is good and the heart is not increased in size, then the murmur requires no further consideration, as in all likelihood it is physiological.

If there be an increase in the size of the heart, but no diminution in the response to effort, and if the circulation is well maintained, then pregnancy may be allowed, even if there be a history of rheumatic fever.

If the size of the heart is increased and the response to effort is limited, then the case requires careful consideration. It must be determined whether the limitations are or are not due to a temporary cause and whether or not the heart muscle has been damaged. If no doubt remains that the heart muscle is damaged, then pregnancy should not be permitted.

If there is present an irregularity of the rhythm of the heart, the nature of this must be carefully investigated. Should the irregularity prove to be of the youthful or respiratory type, then there will be no danger if pregnancy is incurred. If, again, it is due to extra-systoles, no fear need be occasioned by their presence, for these of themselves afford no clue to the state of the heart's efficiency. In such instances opinion must be based on the presence or absence of other signs (size of the heart, response to effort).

Finally, if the irregularity is due to auricular fibrillation, opinion should be based on the circumstances to be described under that heading. The whole subject of irregularity is dealt with later.

MITRAL STENOSIS.

The heart affection which most frequently causes danger in pregnant women is that associated with mitral stenosis following rheumatic fever. Although this has long been recognised, yet we find some authorities to-day declaring that there is little danger. The reason for the diversity of opinion which prevails is that, in many cases, experience is limited. For it is a fact that there are forms of this complaint which are attended with no danger, and there are others which imperil the life of the woman. It is necessary, therefore, if we are to distinguish between the different forms, to look at mitral stenosis far more minutely than has usually been done.

Origin and Progress of the Cicatrising of the Mitral Valves.

Mitral stenosis is, perhaps, the most common of valvular defects with which heart failure is associated. It arises generally in consequence of rheumatic endocarditis, though it may be found in people with no rheumatic history; in these instances a previous history of erysipelas or some other febrile complaint may give a possible clue to its origin.

The condition is never recognised during the acute illness which induces it, for the reason that stenosis does not occur till the cicatrising process which follows the inflammation narrows the orifice. Thus, on account of its origin in scar formation, the lesion is often a progressive one. The stenosis may, however, remain moderate in amount, and offer so little embarrassment to the heart that patients may reach extreme old age with no heart failure. Usually the cicatrising process goes on with varying rapidity until in some cases the mitral orifice is reduced to a mere slit, and the valves resemble a thickened calcareous diaphragm. It is thus always important to bear the probably progressive nature of the lesion in mind. We have here the secret of the varying changes in the symptoms.

Accompanying Changes in the Heart Muscle.

It should also be borne in mind that a similar cicatrising process may be going on in the muscle, causing contraction of the chordæ tendineæ, impairing at other places the functional activity of the heart muscle, and affecting the auriculo-ventricular bundle and depressing its conductivity or producing those conditions which lead to auricular fibrillation. Such changes profoundly affect the efficiency of the heart and modify the nature of its rhythm.

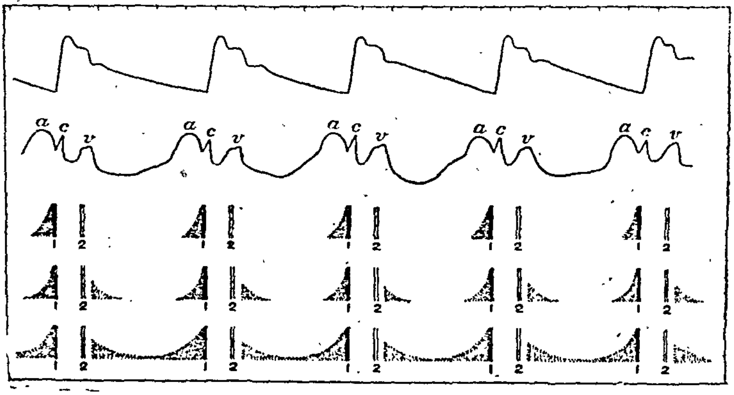

FIG. 6.—Tracings of the radial and jugular pulse with diagrammatic representation of the changes in the murmurs of mitral stenosis. The down strokes 1 and 2 represent the first and second sounds of the heart. The first indication of stenosis is the appearance of the murmur before the first sound, and on reference to the jugular tracing this murmur will be found to coincide in time with the wave *a*, due to the systole of the auricle. With an increase in the stenosis, a short diastolic murmur appears, immediately after the second sound, and this is represented in the middle diagram. A further increase in the stenosis, shown in the lowest diagram, leads to prolongation of the diastolic murmur, which in combination with the presystolic murmur fills up the whole interval between the second and first sounds. (For the next change see Fig. 7.)

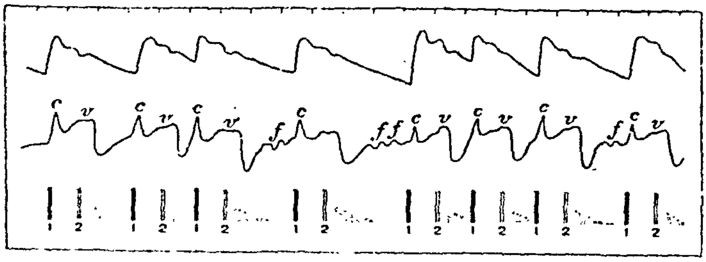

FIG. 7.—After the changes described in Fig. 6 the next change is a sudden alteration of the rhythm of the heart. In Fig. 6 the heart is quite regular; in Fig. 7 it is irregular. The wave *a*, which is a marked feature in the jugular tracing of Fig. 6, is absent in Fig. 7. The presystolic portion of the murmur is also absent in Fig. 7, this feature being best appreciated during the longer pauses of the irregularity. The disappearance of these evidences of auricular activity and the irregular action of the heart indicate the onset of auricular fibrillation. The waves *ff* are due to the fibrillating auricle.

Cause of Heart Failure.

From this it can readily be understood that the manner in which heart failure is brought about in mitral stenosis is somewhat complicated. In some patients embarrassment may not ensue until the narrowing of the orifice has become extreme. In others there may be a fatal issue while the narrowing is yet moderate. In these latter the muscle wall will invariably be found to have been damaged.

Presystolic Murmur in Mitral Stenosis.

The characteristic murmur present in mitral stenosis, the so-called presystolic murmur or auricular systolic murmur, is due to the passage of the blood through the narrowed mitral orifice. During the whole of ventricular diastole the blood is passing through the orifice, but until the contraction of the auricle forces it through with increased rapidity no sound is heard. With advancing cicatrisation, the murmur of mitral stenosis alters and presents peculiarities which have not hitherto been sufficiently appreciated. In the very early stages, some years before the appearance of a murmur, I have detected a slight presystolic thrill. After a time the thrill was accompanied by a murmur. This murmur precedes, or runs up to, and seems to terminate in the first sound; it is audible over a small area around the apex. At the beginning it may not always be present. This murmur is at first short in duration. As time goes on and the mitral orifice becomes narrow, it lengthens, beginning earlier in the diastole. It is of a crescendo character; rising in pitch till it ends in the first sound.

Diastolic Murmur in Mitral Stenosis.

With advancing stenosis of the orifice, another murmur makes its appearance. This one occurs immediately after the second sound, and is heard only in the immediate neighbourhood of the apex beat. At first it is very faint, and not very constant; but in time it increases in volume. This diastolic mitral murmur diminishes in intensity as it proceeds, differing thus (in its diminuendo character) from the presystolic murmur. Frequently during the diastole of the heart we can detect a continuous murmur, beginning loudly, falling away, then increasing in intensity. The first or diminuendo portion of such a murmur is the diastolic mitral murmur, the terminal crescendo portion is the presystolic. The cause of the diminuendo diastolic mitral murmur is the passage through the narrowed mitral orifice of the blood which has accumulated in the auricle during the ventricular systole. This passage begins as soon as the mitral valves open—that is, when the pressure in the ventricle falls below that in the auricle. The development of the murmurs is shown in Fig. 6.

The Appearance of Auricular Fibrillation.

The next change in the character of these murmurs is the sudden disappearance of the presystolic crescendo murmur, the diastolic murmur persisting. Usually this occurs with the onset of grave symptoms of heart failure, the action becoming rapid and irregular. At other times the change takes place with no serious symptom, though the heart invariably becomes irregular. This irregularity is due to the fact that the rhythm of the organ no longer starts with an effective auricular systole. The auricle, on the contrary, ceases to contract as a whole, and passes into the condition of fibrillation (Fig. 7).

In those cases in which the heart's action is slow there is no difficulty in recognising the presence of the diastolic murmur and the absence of the presystolic. The diastolic murmur is, however, sometimes of greater length, and starts immediately after the second sound; in such cases, when the heart's action is rapid, it may fill up the whole diastolic pause, and might then be assumed to be presystolic. If the heart be carefully auscultated this error will be avoided, for the diastolic murmur is not crescendo in character. In auricular fibrillation long pauses may occur between two beats; and if this murmur be listened to then, it will be found that it stops short before the first sound, so that there is a silence between the end of the murmur and the beginning of the first sound (see Fig. 7). In these cases the jugular and liver pulses are invariably of the ventricular form, showing that the auricle, which erstwhile produced the presystolic murmur, is no longer acting.

Heart Failure in Mitral Stenosis.

From the progressive nature of the lesions in the valve and in the heart muscle it will be realised that the symptoms are not constant. The patient, as a rule, comes first under notice in early or middle adult life. The complaints, at this time, are shortness of breath, a sense of suffocation, and palpitation on exertion. In some instances the face is ruddy, with a hue a shade darker than is compatible with the ruddy countenance of robust health: in others there is pallor. At this stage there is little or no increase in the size of the heart and no dropsy. A presystolic murmur can usually be detected. The patient's complaints may be the only evidence we have of the heart failure; they point to an exhaustion of the reserve force. After a period of rest, this exhaustion may disappear, and the patient may go on for years with little further trouble. Some patients, however, break down again, when the symptoms complained of are usually those of the first attack. Frequently, however, a change is found in the character of the murmurs; a diastolic murmur is now commonly noted, and there is sometimes a longer duration of the thrill. These signs imply an increased narrowing of the orifice. In those in whom no further narrowing takes place the murmur does not change. These are the people who go on for many years, and, if females, may bear children with no breakdown. We can thus infer that there is no progressive muscular or valvular sclerosis.

With the increased narrowing of the orifice, as indicated by the appearance of the diastolic mitral murmur, the heart becomes much embarrassed, the symptoms become much more distressing, and finally dilatation of the organ may set in. But even in the absence of progressive narrowing of the orifice dilatation may appear early. This is a sure sign that the rheumatic process has permanently injured the heart muscle. It is to be noted that the left ventricle also dilates in many cases, showing that there is some vital factor concerned in dilatation.

Heart Failure in Mitral Stenosis with Pregnancy.

In mitral stenosis, as I have said, there does occur a degree of back-pressure which is the result of the narrowing of the mitral orifice. This latter event impedes the flow of blood so that there is a tendency to congestion of the lungs; it throws, too, more work on the chambers behind, i.e. the left auricle, and right ventricle and auricle. When these begin to fail the circulation in the lung becomes embarrassed, and then in cases of pregnancy the growth of the uterus adds further to this embarrassment. I have dwelt already on the embarrassment which occurs in the pulmonary cirulation as a result of the widening of the thorax and the impairment of its movements which take place in pregnancy. The early signs of this embarrassment are found in the crepitations at the bases.

But that is not the whole story. The damage due to rheumatic fever is rarely limited to the valves; it frequently extends also to the heart muscle. As a rule no certain evidence of this is available. We are therefore under the necessity of making an inference from the increased size of the heart, the great excitability of its action, and its marked inefficiency. Occasionally, however, we do get more direct evidence. This occurs when the damage invades the bundle connecting the auricles and ventricles, and produces a partial heart block. That point need not concern us here, for the heart block in these cases rarely, if ever, reaches such a degree as to cause embarrassment to the organ in its work. Its significance lies in the fact that it reveals an extension of the disease process from the valves to the wall of the heart.

Estimation of the Significance of Mitral Stenosis in Pregnancy.

Recognising, then, that the sources of danger lie in the narrowness of the mitral orifice, and in the embarrassment of the heart muscle, we are in a position to estimate the danger. Our estimate will take account of several considerations; it will depend in the main on *the rate at which the cicatrisation of the mitral valves is proceeding.*

I have already indicated the means of determining this in describing the changes which occur in the murmurs. These changes afford a basis of assessment, rough, it is true, but still of distinct value. I set them down in serial order thus:

(*a*) When, ten or fifteen years after the causative rheumatic attack, there is only a presystolic murmur, with no signs of œdema of the lungs, and the response to effort is good, then the outlook is favourable. Such an individual can be permitted to become pregnant with fair assurance of safety.

(*b*) When there is not only a presystolic murmur, but also a diastolic murmur. If the heart is normal in size and not too excitable, and if it is capable of a fair response to effort, then pregnancy may proceed. The patient, however, should lead a somewhat restricted life, avoiding especially such effort as brings on breathlessness or palpitation.

(*c*) When, even with a short presystolic murmur, and many years after the causation of mitral stenosis, there is marked inefficiency of the heart, shown by breathlessness on slight exertion, rapid pulse or easily excited palpitation, then there is danger in pregnancy.

(*d*) When the heart is large or irritable, and when effort readily induces palpitation and breathlessness, even if there be no diastolic murmur, then pregnancy should be forbidden. If, in spite of advice, it has been undertaken, the case should be carefully watched, particular attention being paid to œdema of the lungs. If crepitations become persistent after coughing or deep breathing, the advisability of inducing premature labour should be considered. If the percussion note of the lungs becomes impaired, interference is called for.

AORTIC DISEASE.

Aortic Stenosis.

The form of aortic disease which need concern us is aortic regurgitation. Aortic stenosis apart from regurgitation is so rare in the young that I, personally, have never met with it. I repeat here that a systolic murmur at the base—or as some might say "over the aortic area"—should never be looked upon as a sign indicating damage to the aorta; it is not infrequent in people with perfectly healthy hearts. Therefore a systolic murmur at the base of the heart, with a good response to effort and no increase in the size of the heart, is negligible.

Aortic Regurgitation.

It is difficult to determine the relation of aortic regurgitation to heart failure.

I have watched many people with aortic regurgitation lead strenuous lives for twenty or thirty years with no limitation of their powers; others of my patients have suffered early from heart failure of a fatal kind. I have long endeavoured to distinguish between these types. I have found that in the former case the heart has been little, if at all, enlarged and the blood pressure only moderately raised. There has been no wide range between the systolic and diastolic pressures—in other words, there has been an absence of the "Corrigan" or "water-hammer" pulse. When, on the contrary, the heart is greatly enlarged and there is a marked "Corrigan" pulse (systolic pressure in the neighbourhood of 200, and diastolic 70 or 60), and when the response to effort is either greatly restricted or gradually becoming restricted, the outlook is grave.

I am inclined to the view that in the first type damage has been done only to the valves, and that to a small extent, while in the second the heart muscle has been invaded, or the valves have been greatly affected.

Heart Failure and Aortic Regurgitation.

I must, however, confess that I have been baffled in my attempts to understand heart failure in many cases of aortic regurgitation. When this condition sets in, it does so in such diverse ways that clear comprehension is very difficult. Sometimes, for example, effort is restricted because of pain, and this pain may be of a severe kind and easily provoked. Yet the degree of pain seems to bear no relation to the gravity of the condition. Thus, I have found some patients suffer for long periods of years great pain on slight exertion, while in the case of others pain has heralded a fatal issue. In some, again, heart failure is shown only by palpitation on exertion, these individuals suffering neither from pain nor breathlessness.

Some die suddenly with no previous sign of heart failure; others are as suddenly seized by an intense dyspnœa which ends fatally. Only a few have dropsy. I suspect that heart failure in these latter is due to the damage of the muscle more than to the regurgitation.

There is one peculiar feature about the heart failure of aortic regurgitation: when once it sets in, it proceeds apace. We all know what remarkable recoveries take place in people who break down from extreme heart failure with disease of the mitral valve, and even of the heart muscle; I have had no such experience in aortic regurgitation. My experience has been that, once the heart gives way, only very slight improvement ever takes place: moreover, in my own practice every case of aortic regurgitation which developed auricular fibrillation drifted to death.

Aortic Regurgitation and Pregnancy.

My experience of aortic regurgitation complicated by pregnancy is limited to two cases. In these the heart was only moderately enlarged. One was prematurely confined (seventh month). Both made good recoveries, but were left very weak. In both palpitation was easily induced. Neither ever improved. They drifted and died within two years. I have, however, had under my care a number of cases with aortic regurgitation who gave a history of rheumatic fever in their youth. They had borne children, and had not suffered in consequence. Presumably the aortic damage was done during the rheumatic fever attacks. There was only slight enlargement of the heart.

Drawing from my experience in general, I would be disposed to allow pregnancy in a young woman with aortic regurgitation, if there was no "Corrigan" pulse, if the heart was not enlarged or only slightly so, and if the response to effort was good. On the other hand, if there was a forcible apex beat outside the nipple line, a marked "Corrigan" pulse, and a distinct limitation of the response to effort, I should decide that pregnancy ought to be forbidden.

Lettsomian Lectures

[ABRIDGED]

ON

SURGERY OF THE LUNG AND PLEURA.

Delivered at the Medical Society of London on Feb. 7th and 21st, 1921,

BY G. E. GASK, C.M.G., D.S.O., F.R.C.S. ENG.,
SURGEON AND DIRECTOR OF SURGICAL UNIT,
ST. BARTHOLOMEW'S HOSPITAL, ETC.

LECTURE III.—THE PRESENT POSITION OF SURGERY WITH REFERENCE TO DISEASES OF THE THORAX.

THE war compelled the attention of surgeons to a class of work which otherwise they would not have engaged in, and had a very distinct effect on the outlook of surgery towards diseases of the thorax; during the war surgeons learnt to open the pleural cavity, control hæmorrhage, and repair a wounded lung without serious difficulty and with great advantage to the patient. It would be a thousand pities if we were not able to turn these lessons to good account, and it is the purpose of this lecture to demonstrate a few points in which advancement might be made.

APPLICATION OF WAR-TIME EXPERIENCE.

Instead of turning to text-books on thoracic surgery, to see what is the current teaching, it may be useful to turn to the operation theatre lists, and to consider the patients who present themselves for treatment in the casualty departments and wards of the big hospitals. Looking at the operation lists, one is struck by the fact that, except for empyema, any operation on the interior of the thoracic cavity is of rare occurrence, and very few appear to be done; though there must be many patients who would greatly benefit if a safe and satisfactory opening of the chest could be made.

Now that danger from sepsis has been eliminated, the surgeon's only real dread is the danger of producing a pneumothorax. It is essential carefully to consider this point. In order to do clean and efficient work inside the thorax it is absolutely necessary, just as when dealing with the abdomen, to have a good exposure; a wide opening of the pleural cavity or mediastinum therefore becomes a sine qua non. The question may then be asked as to whether such a wide opening either kills the patient or causes serious respiratory disturbance; the answer is that during the war many hundreds of chests were opened without fatality or serious disturbance to the patient; and, moreover, that manipulation of the thoracic viscera was made without causing serious shock. If that can be done in military practice, why can it not be done in civil surgery? Or can the method be improved upon?

PRE-WAR METHODS OF MAINTAINING INTRAPULMONARY PRESSURE.

If one turns to pre-war conditions, one finds that two forms of apparatus were recommended for the purpose of maintaining intrapulmonary pressure during the course of an operation on the thorax and eliminating the dangers of collapse of the lungs; these were the positive pressure chamber and the intratracheal insufflation. The great advocates of the pressure chamber were Sauerbruch of Munich and Willy Meyer of New York, and with its aid they certainly have done some fine work. Willy Meyer had constructed in his hospital in New York a chamber, costing thousands of dollars, for the regulation of pressure as needed. I had the opportunity of seeing this chamber and of arguing the need for it; in Meyer's opinion it makes the operation both easier and safer, and he holds strongly that every thoracic surgeon should use it. It is not easy to traverse the opinion of such experts as Sauerbruch and Meyer, but my own deliberate opinion is that a way ought to be found that does not need such a bulky and expensive apparatus, and that unless such a way can be found thoracic surgery cannot come into daily use.

Intratracheal insufflation, with which is combined anæsthesia, has been used successfully in lung surgery; by this method a slight positive pressure can be maintained in the lung, and rapid and exaggerated movements which interfere with operative manipulation are minimised. The method has certain objections which are not, however, insuperable. These objections are: first, that the initial anæsthesia, before insertion of the tracheal tube, must be deep enough to abolish all reflexes; and, secondly, that the introduction of the tube into the trachea requires a certain amount of practice on the part of the anæsthetist. The method is a good one, has given good results, and must be seriously considered.

THE FACE-MASK METHOD.

Another scheme, which has been evolved during the war, may be called the positive pressure face-mask method. This calls for the use of an air-tight face-mask with a rubber reservoir for the gases. It is, in fact, a slight modification of the gas and oxygen anæsthesia apparatus, and by it a pressure of from 5 to 7 mm. of mercury is easily obtained, and may be raised still higher. This apparatus possesses the great advantage of being simple, cheap, portable, and easy to use. I have never had the opportunity of operating with the pressure chamber, and so I am not able to say much about it from personal experience, but I have used the other methods and can unhesitatingly affirm that the chest can be opened without undue danger to the patient and an intrathoracic operation satisfactorily performed.

Of the two methods—intratracheal insufflation and the air-tight face-mask—I prefer the intratracheal method; but if for any reason it is not possible to have either, the ordinary methods of anæsthesia, such as chloroform or ether, perhaps combined with oxygen, give good results. If these observations are accurate, then the expense and bulk of a pressure chamber is eliminated, and the dread of creating a pneumothorax should not prove a bar to the performance of intrathoracic operations.

DIAGNOSIS.

The next difficulty which confronts the surgeon is that of making an exact diagnosis of the nature and position of a disease within the chest. In the present state of our knowledge it is more difficult to localise, say, an abscess in the thorax than an abscess in the abdomen. The rigid wall of the thorax prevents one feeling a swelling with the hand, and in the case of the abdomen thousands of laparotomies have helped to rectify errors of diagnosis and standardise methods of treatment. It can only be by a patient and careful investigation of cases, together with a systematic investigation of our findings, that like result can be obtained.

If we turn our minds once again to thoracic work during the war, it is evident that the results obtained were due to a careful investigation of the wounds correlated with the X ray findings and localisation of foreign bodies. The same is true of civilian surgery, only here the problem is one of far greater difficulty on account of the multiplicity of the forms of disease and the fact that large numbers of patients suffering from the same variety of disease do not present themselves at the same time.

METHODS OF EXAMINATION.

It may be profitable to run through, very briefly, the various methods of examination which we have at our disposal for the purpose of making a diagnosis.

History.—A real help towards the attainment of a diagnosis is the taking of a careful history—occasionally even a correct localisation of the disease may be gained; attention must be paid to the history of pain, cough, difficulties of breathing, and swallowing.

Physical Examination.—A general survey of the whole patient is necessary as well as the well-known method of auscultation and percussion to which reference need not be made. The need for examination of the sputum, quantitatively, microscopically, and bacteriologically, is too well known to require comment. Then we have cystometry, and the use of the spirometer, bronchoscope, and œsophagoscope—each of which has its own rather limited sphere of utility.

Exploratory Puncture.—This process, performed with an aspirating needle, is often of definite service, though it must be remembered that a negative finding may sometimes be a hindrance rather than a help, and in my opinion patients with all the clinical signs of pus in their chests have often been kept too long from operation on account of the fact that pus was not found with the needle.

X Ray Examination.—In the last few years the X rays have proved to be a great help towards diagnosis and localisation of disease, and they will probably become of much greater value when our interpretation of the pictures has improved. It would, however, be very wrong to rely entirely on an X ray finding and neglect the ordinary clinical methods of examination; it is by a careful summing-up of all results of examination that the good diagnosis, so essential before operative treatment, can be arrived at.

Exploratory Thoracotomy.—This is the right thing to do when all other methods have failed to yield a diagnosis and when it is considered imperative that one should be made; and in my opinion, it is by a judicious use of exploratory thoracotomy that the surgery of the chest will be advanced. With our improved methods of surgery, the danger to life or health from the operation is very slight, and by it it is possible, as in the case of an exploratory laboratory, to gain an accurate knowledge of the diseased organs by direct inspection and palpation.

There is one great difference, however, between an operation for exploring the chest and one for exploring the abdomen; in the former an incision in the wrong place is of great importance, for the bony structure of the thorax does not allow of the amount of retraction of the parietes possible in the abdomen.

METHODS OF OPENING THE CHEST.

The technical difficulties of opening the chest, though greater than those of opening the abdomen, are by no means insuperable. Access to the pleural cavity is usually made from behind or from the side; the medial longitudinal opening, which is the common operation of preference in the case of the abdomen, is reserved for investigations of the mediastinum. Various incisions of the skin are used, the object of which is to bring into view the largest possible portion of the bony thorax; thus, longitudinal, L-shaped incisions, or flap may be employed.

The actual opening of the pleural cavity may be made in many ways. One or more ribs may be removed—usually subperiosteally—and at the end of the operation the edges of the parietal pleura are sewn together if possible, and then the muscles are drawn together over the defect of the rib. Or an osteoplastic flap is made, lifted up, and at the close of the operation replaced in situ. This method has drawbacks: it is followed by considerable pain and gives an ugly wound.

Personally, I have been in the habit of excising 4 inches of rib subperiosteally, and then inserting a rib spreader; by this incision a good view of the interior of the chest can be obtained and a hand can easily be inserted into the pleural cavity. I was led to adopt this plan when operating on soldiers with wounds of the lung, when pieces of splintered rib commonly required removing. I am now of the opinion that an incision through an intercostal space is simpler, gives as good a view, is easier to close and causes less subsequent deformity, and I intend to use this method until a better one is found.

If the exploration has to be done in the upper part of the chest, intercostal retraction may not be sufficient on account of the small amount of spring of the upper ribs. In such a case extra room may be gained by dividing the rib above and below the incision at its costal junction.

CLOSURE OF THE CHEST.

After an opening by means of an intercostal incision, the chest can be closed without difficulty by suture either passed round or through the ribs immediately above and below the incision. The former or pericostal stitch has the merit of being quicker; a curved needle is passed through the whole thickness of the intercostal space at the upper edge of the upper rib; it is then passed under the lower rib and out through the lower intercostal space, just sufficiently removed from the inferior edge to miss the intercostal artery. If the trans-costal stitch is used, holes are punched through the ribs above and below the incision, sutures threaded through, and then drawn tight.

Such a procedure as has just been detailed is that which is advised for an exploratory thoracotomy. I venture to emphasise the importance of this operation, for its usefulness has been abundantly proved in the war, and only by a comparison of the clinical findings and the actual pathological conditions present can improvements in diagnosis be obtained and sound lines for operative treatment laid down. In addition the possibility of the removal of certain forms of tumours can only be gauged when the chest is opened. I would like to repeat that exploratory thoracotomy can now be done without much danger, and there are good grounds to believe that it may become as easy to perform as exploratory laparotomy.

OPERATION OF SPLITTING THE STERNUM.

If the region of the chest to be explored lies in the upper and inner portion of the chest or in the mediastinum, the easiest means of access may be through the sternum.

The trans-sternal route is one of some antiquity; Maister Peter Lowe, writing in the latter end of the sixteenth century, records an operation of trepanning the sternum for evacuation of congealed water from under the sternum, by which he may have meant a chronic tuberculous abscess. Trephining the sternum does not give sufficient room to work, but splitting the sternum gives good access. It may be done in two ways.

One way is to make an oblique incision through the sternum from the second intercostal space into the notch at the top of the manubrium. A curved incision is made, starting in the middle line half an inch above the manubrium sterni, and continued in a curved direction to the third rib, one inch external to the edge of the sternum. The attachment of the intercostal muscles to the sternum in the second intercostal space is then severed and a director passed from the second space to the manubrial notch, keeping immediately under the bone; a special pair of sternum shears is then passed along the track of the director and the bone split. The two surfaces of the sternum are then clawed apart with retractors and good visible access is gained to the upper part of the mediastinum and the pleural space.

A second method is to split the sternum down the middle and turn up a flap consisting of sternum and the attached ribs. Two small trephine holes may be made with a Hudson's trephine, one opposite the second and the other opposite the sixth or seventh interspace; the sternum is then split medially between the two holes by the sternum shears; next, two cuts are made outwards, one from each trephine hole, through the sternum into an intercostal space, and a flap consisting of sternum and attached ribs lifted up. The internal mammary vessels are then brought into view, ligatured, and divided. The costal-sternal flap can then be lifted up and an excellent view of the mediastinum obtained. At the end of the operation the flap can be replaced, sutured in position, and the chest completely closed.

I have only done this operation twice, but it did not present any great difficulty; anæsthesia was smooth, the patient stood it well and made a good recovery. The first operation was performed for a young man with a large tumour of the chest, which turned out to be a cystic teratoma which burst into the pericardium. The incision into the chest as just described gave an excellent view; the cyst was exposed, emptied, a portion of the wall excised and drained. With more experience and practice the whole cyst could probably have been removed. As it is, the patient is relieved of all his symptoms and is healed. The second operation was done for a man who had been wounded by shrapnel at the Dardanelles. Ever since the wound the patient had been unable to work owing to pain, and it was suspected that the ball, which lay alongside the aorta, moving with each pulsation of the aorta, was the cause of the disability. Splitting the sternum in the way just described enabled the missile to be removed without great difficulty and without damage to the patient.

Teratomata of the thorax are of course rare, and it is not suggested that this can become a very common operation, but there are other tumours of the mediastinum for which this route may be useful.

The question is often asked whether it is possible to remove an entire lobe of a lung for such a disease as bronchiectasis or carcinoma. It is not at all difficult to remove a portion of the periphery of the lung; it has often been done for the removal of an injured portion of the lung during the war. Removal of the entire lobe presents certain difficulties; but it has been done successfuly, and may be done again if really required. The difficulty lies in the permanent closure of the bronchus. The method suggested by Willy Meyer recommends itself — namely, an adaptation of the usual way of securing and invaginating the stump of the appendix after appendicectomy. The stump of the bronchus is left as long as possible and then softened by crushing; next the end is ligatured, invaginated, and sewn over.

SPECIAL DISEASES.

It is not intended here to enter further into a discussion of the methods of treating such well-known and gross forms of disease as abcess of the lung or bronchiectasis, nor the various forms of tuberculous diseases; they well may later become the goal of preventive medicine or surgery. Nor will I do more than mention the possibility of handling malignant diseases of the œsophagus or upper end of the stomach. These subjects may become of more importance when methods of intra-thoracic surgery have become easier and standardised, but at present they are hardly practicable. It is, however, worth while carefully to consider the subject of suppuration within the thorax, for that is a common condition, of which the dangers to life and health are great; and our methods of treatment cannot be said to have advanced far since the times of the ancients.

EMPYEMA.

The treatment of an ordinary straightforward case of empyema has not changed markedly for hundreds of years. In olden times it was opened by a cut with a razor through an intercostal space or by burning a hole with a red-hot iron. The latter method was preferred by some surgeons as being less dolorous. Considerable advances have, however, been made with regard to our methods of investigation, for in addition to the physical examination we have the use of the exploring needle and the X rays. There is therefore rarely any excuse for missing an empyema when the pus is free in the pleural cavity. At the present time the usual treatment is to open the chest and drain the pleural cavity by means of a rubber tube, either through an intercostal incision or by excising an inch or so of rib. As the discharge lessens the tube is shortened, and if all goes well, as it often does, the partially collapsed or compressed lung expands, becomes adherent to the parietal layer of the pleura, and the patient is cured after a few weeks, though the chest may show some permanent flattening on the affected side. But all cases do not run such a favourable course; in many patients the external wound tends to close before the pleural cavity has become obliterated, and has to be reopened perhaps two or three times in order to evacuate a collection of pus. In such cases a permanent cure may still be obtained, at the expense of a more or less collapsed lung and a greatly thickened pleura. In other patients—luckily a minority—there is a persistent sinus, which if untreated lasts for years and is a source of grave danger.

IMPROVED TREATMENT OF ACUTE EMPYEMA.

It is universally recognised that a collection of pus in the pleural cavity is a dangerous condition, and it behoves us to consider whether the classical treatment can be improved on.

The first improvement to be noted is that which has followed making an air-tight closure round the drainage-tube which is inserted into the chest, and leading a tube from this to a vessel partly filled with water under the bed, so that pus may drain out and air may not be sucked back; by this device the lung is encouraged to expand more quickly, so as to obliterate the pleural space. It is not necessary to dilate on the many devices which have been invented to accomplish this end.

Another procedure which is still very much in the experimental stage, and therefore sub judice, is that of evacuation of the pus in the pleural cavity by open operation followed by immediate complete closure. During the last war medical officers had many cases of hæmothorax to treat. A certain proportion of these became infected and developed empyema, being usually opened and drained in the classical way. It was found, however, that if the infection was diagnosed at a very early stage the chest could be opened, the blood clot cleared out, and the chest closed without having to be drained. It is true that the number of patients treated in this way was small, and that there were many failures requiring subsequent drainage. It is also true that once infection had been established for several days the method appeared to be useless; moreover, success depended greatly on the amount of infection and the nature of the infecting organism, for in the presence of streptococci failure was the rule.

It has been suggested that this method should be applied to empyema in civilian patients, and in a few cases it has been carried out successfully. Before making any pronouncement in its favour it is, however, necessary that a much larger number of observations should be made than are now available, and in any case good judgment must be used to avoid the danger of allowing pus to reaccumulate. In general terms it may be said that the diagnosis of empyema must be made very early, and that in the presence of streptococci it is safer to drain rather than to close the chest.

TREATMENT OF A LOCALISED EMPYEMA.

The diagnosis of empyema is not always an easy matter, especially when pus is not present in any great quantity, or is so thick that it cannot be drawn through a needle, or when it is walled off by thick fibrous adhesions, or is lying between the lobes of the lung. In many such cases it has been the custom of clinicians to delay operating until pus has been located by means of the exploring needle. Often the abscess is never located by this means, and the pus tends to accumulate and track until it bursts into a bronchus and the patient commences to spit pus. It is well known that in this way a spontaneous cure may result, but it is at the expense of a great deal of discomfort and distress to the patient, and under less favourable circumstances pus spitting may continue for years with all its uncomfortable sequelæ. I submit that in such a case, when there is good reason to believe from the clinical findings that there is pus in the chest, and when it has been found impossible to localise it either with the exploring needle or the X rays, an exploratory thoracotomy should be undertaken; by this operation lives may be saved or prolonged convalescence shortened.

A CASE OF LOCALISED COLLECTION OF PUS.

To illustrate this point the following case may be quoted:—

A man, aged 37, was admitted to hospital suffering from a perforated gastric ulcer. The diagnosis was made promptly, the abdomen opened, the hole in the stomach sutured, and a gastro-enterostomy performed. A large amount of fluid and stomach contents was evacuated from the peritoneal cavity, and the abdomen closed except for a drain which was removed 48 hours later. The patient did well, the pulse and temperature falling to normal. Then suddenly three weeks after the operation the patient had a sudden sharp pain in the lower part of the right side of the chest, accompanied by a rising temperature. It was suspected that he had developed a subphrenic abscess, and that this abscess had caused infection of the pleural cavity, but a careful examination did not reveal one. Later he developed signs of pleurisy and some dullness over the base of the lung and he began to cough and spit. The temperature remained raised and a leucocytosis was present. He was needled on several occasions in various places, but no pus was found. A skiagram showed a general opacity of the lower part of the chest, but no localised abscess.

Acting on the belief that pus was present although it could not be located, an exploratory thoracotomy was undertaken. About four inches of the posterior portion of the ninth rib was excised, the pleural cavity opened, and a rib spreader inserted. The lung was found adherent by recently formed lymph to the parietal pleura. Search was made, first in the space between the lung and the diaphragm on the assumption that it would be there that pus would accumulate if infection had come from a subphrenic abscess. No pus was found. The exploration was then carried higher up and a localised collection of pus was found close to the spine, shut off from the general pleural cavity by layers of soft yellow lymph about a quarter of an inch thick. This cavity was drained, the temperature and pulse fell to normal, the coughing ceased, and the patient made a rapid recovery.

The collection of pus in this case did not form a rounded abscess, but was spread out in quite a thin layer over about three or four square inches of lung surface, and it was walled off by a thick layer of soft lymph. This will no doubt explain the difficulty of hitting it off with the needle, and the fact that it was not recognised with X rays. There is little doubt that had the patient been left without evacuation of the abscess, death, or long illness resulting in a more or less permanently damaged lung, would have supervened.

CHRONIC LOCALISED EMPYEMA.

There is another type of case which may be described as chronic localised empyema, which has its origin in the pleural cavity, becomes shut off by firm adhesions, and which discharges itself generally very incompletely via a bronchus. Such cases are well known; they tend to run a very chronic course and lead to great and permanent disability. They call emphatically for surgical assistance, though the treatment given is too often conservative. The following case may be used to illustrate this point:—

During the epidemic of 1918 a hospital nurse acquired influenza followed by pneumonia and an empyema, which was treated by resection of rib and drainage. The empyema healed, but the patient was not cured, because for the succeeding nine months she had periodic attacks of fever, associated with cough and expectoration of pus. These attacks lasted a few weeks and then almost disappeared, but the patient was unable to do any work. The affected side of the chest was smaller than the opposite side and the lung did not expand well. The fingers were clubbed and there were the signs of a long-standing collection of pus within the chest; in addition X rays showed a considerable opacity. An incision was made along the sixth rib in the post-axillary line, about three inches of bone were resected, and the chest was opened by means of a rib spreader. Pus was found lying between the lobes, and there was immense thickening of the pleural membrane round it. The pus was evacuated and the thick mass of fibrous tissue dissected off the lung. The cavity was plugged temporarily with gauze soaked in flavine and the chest closed secondarily.

The patient made a good, quick recovery and is now working hard as a nurse. Had that patient been left alone she might have recovered by coughing up the pus, but convalescence would have been long and she might have become a chronic invalid. The only satisfactory way of dealing with the abscess was by an operation which gave a clear access to the affected part; and that operation is both safe and satisfactory.

TREATMENT OF A CHRONIC EMPYEMA SINUS.

Unfortunately many patients for whom a drainage operation has been performed do not heal, but are left with a permanent discharging sinus. The treatment of these people is very difficult and unsatisfactory; in hospital practice they are constant attenders in the casualty department until they become dissatisfied and drift away to other hospitals or infirmaries. In an empyema of long standing, whether it has been opened or not, the pleura (both visceral and parietal) is converted into a layer of fibrous tissue often half an inch or more in thickness. The lung in these cases is literally imprisoned by fibrous tissue; it cannot possibly expand and fill the cavity, no matter how hard the patient blows bubbles or does thoracic exercises. Meanwhile the fibrous tissue tends to contract, pulling the diaphragm up and the ribs in, though the rigidity of the bony thorax is generally too great to allow sufficient collapse to secure union of the visceral and parietal layers of the cavity.

There seem to be only two accepted methods of treating this condition. One is to remove a sufficient quantity of the bony thorax, so as to allow the parietes to fall in and obliterate the cavity; this is done by means of the well-known operation of Estlander.

The other method is, remove the visceral layer of fibrous tissue so as to allow the imprisoned lung to expand up to the parietes and so obliterate the cavity. For this purpose the operation known as decortication has been devised and is commonly associated with the great name of Tuffier. Estlander's operation is objectionable, for it spells great and permanent deformity of the chest and a permanently collapsed lung, yet it may be right and timely to save life even as amputation of a limb may be necessary.

The ideal treatment is to remove the fibrous sheathing and allow the imprisoned lung to expand, but it must be remembered that to be successful the operation must not be delayed so long that the collapsed lung has itself become hard and fibrous and no longer capable of expansion. The removal of the fibrous tissue is in itself not difficult, provided that good access can be gained especially towards the upper part of the cavity where the layer is generally thickest.

The difficulties which I have *myself* encountered were, firstly, that the thick fibrous walls did not allow [illegible]d retraction of the chest, and secondly, that the [illegible]ll available working space makes it difficult to dissect away the thick fibrous tissue at the upper extremity of the pleural cavity, and it seems that the lung will not expand readily even if the bulk of the organ is freed from tissues and yet the apex is still bound down. Failures have been at least as common as successes, yet it seems clear that the method is a sound one, and that with increased experience a good operation will be evolved. Like most forms of treatment it must be undertaken early; the amount of time which should be allowed before it is performed must, however, be left to the judgment of the surgeon.

SKIN-GRAFTING THE SINUS.

There is yet another device for curing a persistent empyema sinus which has been used by Beck, of Chicago. He has skin-grafted the interior of the tissues and has shown patients cured in this manner. The method is not likely to be widely used; it is difficult to carry out, and the patient is left with a deep hole in the side, covered by skin, but very difficult to keep clean and non-odorous.

TUBERCULOSIS OF THE LUNG.

What is the position of surgery at the present time towards tuberculosis of the lung? About 1800 a certain number of surgeons conceived the idea that portions, or indeed the whole, of the lung might be removed. Animal experiments were performed which proved that portions could be removed with safety, the remaining lung expanding and filling the pleural cavity. On the strength of these experiments a certain number of operations were undertaken for the removal of portions of lung affected by tuberculosis.

With regard to these operations it may be said that they are never likely to have a wide application; not only because it is nearly certain that more than one part or more than one lung is affected, but also because in the early stage (in which alone surgical measures would be justifiable) there is a good chance of securing a cure by medical methods. There is a very general feeling, too, among surgeons that surgical treatment of tuberculosis should become less and less as our knowledge of preventive and curative medicine increases. As an example of this statement, one may turn to the treatment of tuberculous glands in the neck. Ten or fifteen years ago the removal of tuberculous glands in the neck was one of the common operations in hospital; now it is rare, for the glands are cured in other ways.

Of collapse of the lung by nitrogen no mention need be made here, for it is fully dealt with in medical books. When nitrogen replacement fails owing to adhesions preventing collapse of the lung, it may become necessary to remove a certain amount of the bony thorax so as to allow the chest wall to fall in, so that in that respect surgery may be of use.

CONCLUSION AND SUMMARY.

It is now time to sum up the conclusions to be arrived at and to state the point of these lectures. It has been pointed out that during the past 600 years surgery of the chest has at times receded and at times advanced, and that at no period has such progress been made as occurred during the last war. During that time surgeons overcame their dread of opening the closed thorax and learnt to repair a wounded lung and restore it to its normal function. It has also been demonstrated that in civil practice it is possible with safety to the patient and without expensive apparatus to open the chest widely and to deal with discarded processes which previously were unrelieved. The evidence that has been brought forward is intended as proof that the operation of thoracotomy is a sound and reasonable one.

I submit that more and more operations on the chest should be undertaken, and that with a wider experience the operation of thoracotomy will become as useful and ordinary as that of laparotomy.

THE OPERATION OF VENTROFIXATION,

WITH THE AFTER-RESULTS OF 220 CASES.

By J. E. GEMMELL, M.B., F.R.S. EDIN.,
SENIOR HONORARY SURGEON, HOSPITAL FOR WOMEN, LIVERPOOL; HONORARY SURGEON, LIVERPOOL MATERNITY HOSPITAL;
AND
A. LEYLAND ROBINSON, M.D. LOND., F.R.C.S. ENG.,
HONORARY ASSISTANT SURGEON, HOSPITAL FOR WOMEN, LIVERPOOL.

VENTROFIXATION is a generic term for a large group of operations in which widely differing methods have been used to fix the uterus to the anterior abdominal wall. There is no doubt that many of these methods have been anatomically unsound, and have been followed by post-operative complications and obstetric difficulties, or the so-called fixation has resulted in the attachment of a long and futile band of peritoneum to an otherwise unaltered uterus. Such bands, which every gynæcologist has seen and excised, may easily lead to strangulation of bowel, and are therefore not only useless but dangerous. In other cases where true fixation has been achieved, entirely unsuitable parts of the uterus have been selected as fixation points—e.g., the upper segment, the fundus and even the posterior surface. A uterus anchored in this way is incapable of symmetrical enlargement, and subsequent pregnancies will either terminate in early abortion or end in some form of dystocia at term. In view of these facts it is perhaps not surprising that the operation is regarded with disfavour in some quarters. Such sequelæ certainly condemn the type of operation concerned and emphasise the danger of bad methods, but do not prove that the principle of ventrofixation is fundamentally unsound.

It is the purpose of this paper to show that a properly performed ventrofixation is free from undue risk, does not interfere with subsequent pregnancy or labour, and in a large majority of cases permanently cures the patient of those symptoms for which the operation is undertaken. Our conclusions are based on a number of cases operated on at the Hospital for Women, Liverpool, by one of us (J. E. G.), using one particular method throughout the series. Of 470 patients operated on prior to December, 1917, 220 have been traced. In 115 cases the operation was performed for retroversion, and in the remainder (105) as a part of the treatment of prolapse.

Indications for Operation.

Retroversion—congenital retroversion and retroponation—with a freely mobile uterus of normal size is symptomless, and in the absence of infection, repeated abortions, or sterility, does not justify operative interference.

Backache and dysmenorrhœa in such cases are due to associated neurosis, and the results of operation are disappointing—sometimes actually harmful. On the other hand, a bulky, tender, fixed, retroverted uterus is in a different category. Many of these cases follow labour and in most of them some degree of infection is present. Backward displacement by stretching peritoneal ligaments and kinking blood-vessels and lymphatics produces pain, enlargement of the uterus, œdema of the endometrium, and menorrhagia; menstruation becomes painful and prolonged, leucorrhœal discharge is increased, and other symptoms, such as dyspareunia and repeated abortions, may follow. If unrelieved chronic ill-health ensues, a condition of semi-invalidism characterised by a well-defined group of symptoms. (Table I.)

Prolapse.

We consider ventrofixation to be a necessary part of the surgical treatment of severe prolapse in young fertile women; for women past the menopause an abdominal operation is often undesirable and also unnecessary, for any lesion can be permanently cured by vaginal methods, either colporrhaphies or the interposition operation. We readily concede that prolapse can be successfully treated in young women by vaginal plastic work alone, but to accomplish this in severe cases (50 per cent. of our cases were complete procidentias) very sweeping colporrhaphies must be carried out, and usually amputation of the cervix.

Such sacrifice of tissue is inimical to subsequent conception. We have found that of 27 cases in which amputation of the cervix was performed, only 4 became pregnant afterwards (14·0 per cent.), compared with 59 subsequent pregnancies in the remaining 193 cases (30·5 per cent.—this figure should be higher as some of the patients were unmarried). Further, if pregnancy does occur the risk of perineal and vaginal lacerations during labour must logically be increased; in other words, there is a risk of reproducing the original lesion in an exaggerated form.

We believe that if ventrofixation (or some comparable abdominal operation) is practised in addition to the necessary vaginal repair, the latter may be safely restricted within moderate limits and the cervix, unless obviously diseased, conserved.

The advantages of a moderate colporrhaphy over a very extensive one need no emphasis. Sexual life and conception are not interfered with and labour entails no special risks. We are not concerned with the relative merits of ventrofixation and other abdominal procedures such as Gillian's operation, for whilst we have seen excellent results in isolated cases, we have had no experience of a large number of results. (Table II.)

Description of Operation.

The necessary vaginal work which is first carried out consisted of the following operations in our cases:—

Anterior colporrhaphy ..	4	Dilatation and curettage ..	57
Posterior colporrhaphy ..	38	Trachelorrhaphy	14
Anterior and posterior colporrhaphy	67	Amputation of cervix ..	27
		Hæmorrhoids	5

Abdominal Incision.—A small two- or three-inch median incision is made extending from the symphysis pubis upwards, or alternatively the transverse (Pfannenstiel) method may be used; the latter, which was employed 73 times, gives satisfactory access, and leaves a sound and almost invisible scar, and can be safely recommended in the absence of infection. After opening the peritoneum the uterus and adnexa are examined for the purpose of determining their exact position and the presence and nature of lesions other than mere displacement. Any such lesions are then dealt with.

Additional abdominal procedures in the present series include:—

Separation of adhesions ..	25	Myomectomy	10
Salpingectomy	14	Herniotomy	6
Double salpingectomy ..	3	Appendicectomy	2
Salpingostomy	2	Utriculoplasty	1
Ovariotomy	10	D'Artigue's operation ..	1

In this case as D'Artigue's operation was found to be unsatisfactory when completed it was disregarded, and ventrofixation carried out in the usual way. The amount of associated infection is worthy of notice.

Formation of Bladder Septum.—The peritoneum covering the bladder is picked up in the middle line with a succession of Spencer Wells forceps arranged in file and extending from the utero-vesical attachment to the upper border of the symphysis pubis. It will be noticed that the latter point coincides with the parietal peritoneum at the lower angle of the incision.

Using these forceps as guides, a catgut suture is inserted in the centre of the utero-vesical fold and continued as a running stitch through the peritoneum covering the bladder, passing downwards, forwards, and upwards in the middle line until the parietal peritoneum is reached at the lower angle of the wound. This stitch is both continuous and interrupted, for the two ends are knotted at short intervals, thus bunching or gathering the peritoneum into one mass and forming a median septum stretching across the utero-vesical pouch between the uterus and the abdominal wall; the two ends of the suture are finally brought through the rectus fascia on each side, just above the symphysis pubis.

This septum effectually obliterates the space which would otherwise exist below the fixation area, converts the fixation band into a ridge, and hence by preventing the formation of adventitious bands and peritoneal fossæ, eliminates the danger of post-operative strangulation of bowel. It is, therefore, merely a safety device and does not act, and is not intended to act, as a uterine support. It must interfere to some extent with the upward movements of the bladder, but in actual practice such interference is negligible, for that viscus ascends freely on each side of the septum, there is no diminution in working capacity and no disturbance of the mechanics of micturition.

Fixation of Uterus.—The uterine wall immediately related to the utero-vesical fold of peritoneum is part of the lower uterine segment; its function during labour is passive dilatation. Repeated examinations during Cæsarean sections have failed to show any elevation of the level of this reflection. Fixation of a point that normally remains stationary cannot interfere with the symmetrical development required by pregnancy, or retard dilatation during labour. This area is therefore selected as the fixation point—i.e., the anterior surface of the uterus immediately above the attachment of the utero-vesical reflection of peritoneum.

Two silkworm-gut sutures are introduced with a round-bodied needle so as to include a fair bite of muscle, and then drawn through the rectus sheath immediately above the catgut suture forming the baldder septum.

It is important to notice that the peritoneum is deliberately avoided in these fixation sutures. The uterine muscle is thus brought into intimate contact with the rectus fascia and muscle, and a fibro-muscular ligament is formed at the junction. Closure of the abdomen is carried out in layers in the usual way. The operation is a simple one and may be completed in 15 to 20 minutes.

Results.

There are two chief methods of investigating results: the objective, in which the surgeon examines the patient and relies chiefly on his own findings, and the subjective, in which the patient's own statements are accepted as criteria of success or failure. Both these methods are open to criticism, for whilst an operation may be technically perfect it is not a true success if symptoms persist; conversely, symptoms complained of by the patient arise in some instances quite independently, and may have no connexion with the operation or with the original condition for which the operation was performed. It is, of course, obvious that the success of any operation can only be measured in terms of symptoms cured, and therefore the subjective method is, on the whole, more trustworthy, if sometimes unfair to the surgeon.

Although we have examined a good number of our patients (25 per cent. at least), we have used this method (the subjective) exclusively in assessing the results, and we think it desirable to publish the questions asked in toto to show the completeness of our inquiry.

Dear Mrs. ——

You were operated upon by Dr. Gemmell some years ago at Shaw Street Hospital. He is anxious to know the result of the operation, and will be much obliged if you will answer the following questions and return the completed form. He will be glad if you will also report at Shaw Street, any Tuesday or Friday, between 2 and 3 o'clock.

1. Have you any complaint of the womb, &c., at present? If so, when did you first notice it?
2. Have you had any children since the operation? How many? Give dates.
3. Have you had any miscarriages since the operation? When did they occur? How many months were you pregnant?
4. Had you any special complaint when carrying these children?
5. Were the labours easy? Mention any special points such as instruments or operations?
6. Have you any difficulty in passing or holding the water?
7. Are your bowels regular? Have you any difficulty in holding the motions?
8. Are your periods regular and free from pain?
8a. Have you any discharge between your periods?
9. Is your general health good?

General Results.

1. One patient died from sepsis, aggravated by her own action in removing the dressing and walking to the lavatory the day following operation.
2. There were no cases of intestinal obstruction.
3. 179 patients described themselves as cured (including 43 women with 72 pregnancies).
4. Forty-one patients complained of symptoms, of whom 20 had been confined of 31 children and attributed their symptoms to labour; 14 of the remainder stated their complaint to be either slight or occasional, leaving seven patients as possible failures.

Effect of Ventrofixation on Conception and Pregnancy.

Conception.—The fact that 63 patients conceived subsequently proves that ventrofixation does not prevent conception in fertile women.

Sterility.—Of eight patients specially operated on for sterility (with retroversion) three became pregnant afterwards, one woman after seven and a half years of marriage, and two others after four and three years respectively. Of 28 married nulliparæ, eight afterwards had children.

Abortion.—Prior to operation 36 patients had aborted 58 times; afterwards 12 women aborted 13 times, eight of the latter had also borne living children since operation and had aborted previously (i.e., before operation). Of the remaining four patients, one attributed the miscarriage to overwork (when ignorant of her condition). In the second definite pelvic infection was found at the operation, necessitating left salpingectomy, whilst no reason was alleged for the remaining two cases, of whom one has since gone to full term.

Repeated Abortions.—Five patients were operated on for multiple abortions with the results shown in Table III. In view of the complexity of these processes—conception and sterility—it is impossible to dogmatise from a few cases, but it seems fair to conclude that the chances of conception are not diminished, and that by reducing the frequency of abortions, ventrofixation actually increases fertility.

Effect on Pregnancy.—Although one might have expected patients to complain of abnormal pains during pregnancy, actually only two patients did so, seven others mentioned various symptoms, such as swollen legs, hæmorrhage, cough, which could clearly have no bearing on the operation.

Effect on Labour.—The figures in Table IV. need no comment and permanently dispose of the idea that ventrofixation necessarily means dystocia.

Effect on Symptoms.—Patients without symptoms: 179 patients remained free from symptoms for periods ranging from three to 15 years, averaging seven. (Table V.)

Patients with Symptoms.—Forty-one patients (18·6 per cent.) complained of symptoms. Of these 20 attributed their trouble to labour.

Effect of Labour on Ventrofixation.—It is universally admitted that labour is the most potent of uterine displacements, and every plastic operation is severely tested by parturition. It is, of course, impossible to prevent vaginal lacerations by any form of abdominal procedure (excluding Cæsarean section), and we have already pointed out the increased likelihood of such injuries where extensive colporrhaphies have been carried out. In the absence of adequate repair vaginal prolapse must follow, and in those of our complaining prolapse cases that have been examined we have invariably found a vaginal lesion, with the uterus in normal position. So far we have not seen a long hypertrophied cervix, although such a condition is a natural sequence in advanced cases where the pelvic floor has "gone" and the uterus is supported solely from above.

To some degree these recurrences are preventable, lacerations and injuries, generally speaking, are commonest and severest in small pelves in which antenatal examination and pelvimetry (so often neglected) would reveal the contraction and suggest a remedy. The number of instrumental deliveries is excessive and unnecessary, and lastly, forceps are frequently "mis"-applied before the cervix is fully dilated on the principle that might is right. (Table VI.) The percentage of forceps deliveries

(75 per cent.) is striking in conjunction with the fact that only one patient mentioned stitches. It must also be remembered that 43 patients successfully passed through 72 confinements without subsequent complaint.

The remaining 21 patients who complained of symptoms had not been subjected to the strain of parturition. They fall into two groups, which may be briefly considered and tabulated. Group A, 10 prolapse patients (Table VII.), and Group B, 11 retroversion cases (Table VIII.).

In connexion with Group A we make the following suggestions :—

TABLE VII.—*Ten Prolapse Patients with Symptoms in the Absence of Confinements.*

—	Age of patient in decades.			Original lesion.		Length of time elapsing before onset of symptoms.								Nature of complaint.			
	20–30	30–40	40–50	Partial prolapse.	Complete prolapse.	1	2	3	4	6	7	8	9	Occasional weakness	Slight falling of womb.	Discomfort only on exertion.	Bearing-down pain.
No. of patients..	1	1	8	5	5	2	1	2	1	1	1	1	1	1	2	5	2

TABLE VIII.—*Eleven Retroversion Patients with Symptoms in the Absence of Confinements.*

Case No.	Married or Single.	Age.	Children.	Chief symptoms before operation.	Years since operation.	Present complaint.
26	S.	30–40	0	Dysmenorrhœa and menorrhagia.	6	Cured for four years: dysmenorrhœa for two years.
43	S.	30–40	0	Dysmenorrhœa and menorrhagia. Abdominal pain.	6	Dysmenorrhœa and abdominal pain. (NOTE.—This patient had three previous abdominal operations.)
44	S.	20–30	0	Dysmenorrhœa, leucorrhœa and menorrhagia.	4	Cured for four years, bearing-down for three months.
54	M.	40–50	3	Bearing down, leucorrhœa and menorrhagia.	3	Pain continuous since operation.
68	M.	20–30	1	Abdominal pain, menorrhagia, leucorrhœa.	5	Occasional pain in stomach.
97	M.	20–30	0	Dysuria, dysmenorrhœa, backache.	4	Bearing-down on and off.
164	M.	40–50	11	Abdominal pain, backache.	11	Abdominal pain. Uterus found retroverted.
200	M.	20–30	1	Menorrhagia, dysmenorrhœa, leucorrhœa.	7	Cured for four years, now slight pain at periods. ? Recurrent infection.
233	S.	40–50	0	Abdominal pain, dysuria, leucorrhœa.	8	Tired strained feeling. T.B. tube was removed at operation.
234	M.	30–40	3	Menorrhagia, dyspareunia.	8	Bearing-down. Salpingectomy at operation (?T.B.).
309	M.	40–50	5	Abdominal pain, dysmenorrhœa.	10	Cured for seven years; dysmenorrhœa lately.

1. The age of patients at the time of operation (eight cases were between 40 and 50 years of age), makes the menopause a likely cause of symptoms, definitely proved in one or two cases examined by us—e.g., patient complains of a bearing down; the uterus and vagina in perfectly normal position; senile vaginitis found to be responsible for symptoms.

2. The interval elapsing before the appearance of symptoms—in four cases six or more years after operation.

3. Muscle overstrain and lack of tone is an undoubted factor—one patient, a thin woman of 50, was running a boarding house single-handed; another was a chronic bronchitic. Two other patients had developed inguinal herniæ, whilst deficient musculature was further exemplified by obesity and visceroptosis.

4. As every case qualified her answer it is fair to assume that all were improved.

With reference to Group B, Case 164 (Table VIII.) is important as being the only one in which we found the uterus retroverted. The original notes describe the uterus as enlarged and heavy, but omit to mention the suture material used; still this must be regarded as a primary operative failure. Neurosis is a factor in Cases 43 and 54. Recurrent infection and the menopause in Cases 200, 233, and 234. On the whole it is clear that the majority of these patients were benefited by the operation.

Considering these results as a whole we are convinced of the merits of ventrofixation. It was evident from the letters received from places so far apart as India, Canada, and Greece that many patients were very appreciative and attributed their excellent health to the operation. Although 18·4 per cent. complained of symptoms, such symptoms were frequently described as trivial, and do not disturb our confidence as to the value of the procedure.

Conclusions.

1. Ventrofixation is a simple and useful operation for certain types of uterine displacement.

2. Post-operative intestinal complications do not occur and subsequent gestation and parturition are not interfered with if suitable technique is employed.

3. The frequency of abortion is diminished and fertility increased.

4. The percentage of patients subjectively cured is satisfactory, and the occurrence of symptoms after operation is largely due to factors beyond the control of the surgeon, namely: (*a*) Labour. (*b*) Over exertion. (*c*) Recurrence of infection. (*d*) The menopause. (*e*) Neurosis.

THE TREATMENT OF URINARY INCONTINENCE BY ELECTRICAL METHODS.

BY F. HERNAMAN-JOHNSON, M.D. ABERD., D.M.R. & E. CANTAB.,

DIRECTOR OF THE X RAY AND ELECTRICAL SERVICE, THE FRENCH HOSPITAL, LONDON; PHYSICIAN TO THE X RAY DEPARTMENT, MARGARET-STREET HOSPITAL FOR CONSUMPTION, ETC.

URINARY incontinence does not in any way threaten life; if it is nocturnal only, it does not directly interfere with work or pleasure; and even when the control is imperfect by day as well as by night, the use of a receptacle usually enables the patient to carry on his business, and to take part, more or less, in the social doings of ordinary people. Nevertheless, this particular disorder is responsible for more distress of mind than that caused by many troubles of a physically more serious nature. In the young child the symptom is distressing to the parents rather than to the patient; but with the first plunge from home into the great world—even though this be represented at first by something no more formidable than a preparatory school—the conviction is brought home to the sufferer that he is not as other boys. Often he begins to feel a sense of shame, and this increases as he grows older.

When treatment fails, parents and patient are often consoled with the prophecy that all trouble will disappear with the onset of puberty. The boy resigns himself to his complaint, in the confident expectation that he will be better by the time he is 15 or 16; and, about that age, partly because the changes of adolescence really have in many cases a beneficial effect, partly because of the force of suggestion, the disorder often tends to improve, or disappears. But not always by any means. And the case which does not improve about the age of 15 is increasingly difficult to deal with. The previous suggestion of cure now becomes a counter-suggestion, and there is a great danger of the patient becoming morbid.

Wide Distribution of the Condition.

How many young men who inexplicably refuse invitations, who are "curious" in their behaviour, who shun the society of the other sex, are thus afflicted? We do not know. But the late war showed that of apparently healthy recruits, in all countries and from all classes, an unexpectedly large percentage were afflicted with functional urinary troubles. Yet in private practice the condition seems rarely met with among otherwise healthy adults. I venture to suggest that it is in reality fairly common, but that the victims, partly from a feeling of false shame, and partly from a belief that they are too old to be in any way helped, do not often seek medical advice. Girls appear to suffer much more rarely than boys, but when it occurs in them the condition is even more distressing. Whatever the sex it is important to cure the condition if possible during the period of home life.

When control has never been properly established, there is often a general nervous defect—the child is somewhat backward, stammering is frequent, and there is often some diurnal as well as nocturnal trouble. In other cases the disorder comes on gradually between the ages of 4 and 5, sometimes in children who seem to be in every other respect normal.

Possible Causes.

In either case the most careful search should be made for possible exciting causes, which may be either local or general. The two things most likely to be directly productive of incontinence are stone in the bladder and scybalæ in the rectum. Vesical calculus in young children is more common than is generally believed. X ray examination will detect 90 to 95 per cent. of all bladder stones; for the residue, consisting of uric acid, cystoscopy is necessary. Intestinal worms are a source of both local and general nervous irritation. A long prepuce has been much blamed as a local cause, but to remove it simply because it is long is not a justifiable proceeding. There is always some risk, however slight, in the administration of a general anæsthetic and incontinence is too often unbenefited. Unless, therefore, there is some other reason for the circumcision in addition to that of possible benefit to the enuresis, it should not be performed until other measures have failed. Adenoids are of great importance: not that one can count upon their removal effecting a cure, but a cure by other means is impossible so long as the handicap of adenoids or "tonsils and adenoids" is allowed to remain.

Treatment by Drugs and Suggestion.

Drug treatment can be alluded to only very briefly. Belladonna is often much abused; it should be employed only with a view to "breaking the habit," and never be pushed for more than two months at a time. It is useless and even harmful when there is definite lack of tone in the sphincters: here nux vomica is indicated. Thyroid (advocated by Dr. Leonard Williams) is useful in some cases, especially when there are adenoids. Alkalies may be useful where the urine can be shown to be hyperacid.

Suggestion treatment, hypnotic or otherwise, while of great value, may fail when employed alone. Most cases are compounded of a physical and a mental element; and either the first or the second may predominate. In the latter event psychical methods have a great field; but if they do not succeed quickly an auto-suggestion of incurability may be set up, and the difficulty of cure is much increased.

Electrical Treatment.

Electrical treatment has been employed for nocturnal enuresis for many years—in fact, reference can be found to it in text-books half a century old. Galvanism and faradism were then used with some success. We have now added the high-frequency condenser electrode to our armamentarium. Interrupted currents are employed to produce rhythmical contraction of the abdominal muscles; the condenser electrode is inserted per rectum. In this latter case the patient feels nothing, but a spark may be drawn from any part of his body. These methods both aim at increasing local and general tone. They should always be employed for some weeks before anything more drastic is contemplated. For the first week or ten days, the method should be unaccompanied by any verbal suggestion, other than an initial explanatory statement in the case of older children. These should be told that the brain controls the bladder even during sleep, provided that it gets proper messages as to the state of affairs there; and that the effect of the electricity will be to increase the strength of the messages—"to make the telephone bell ring more loudly."

Combination of Suggestion with Electrical Treatment.

If there is no improvement within ten days a definite suggestion should be made to the effect that, although the bladder is not yet strong enough to hold its water all night, yet its distress signals will wake the patient before an accident happens. This is often successful, even though previously, without the use of electricity, the suggestion may have been made in vain. (The kind of suggestion here referred to is, of course, ordinary "waking suggestion" and persuasion: hypnosis should not be employed except by experts in the subject.) If the patient can be got to wake regularly feeling a desire to micturate, the battle is practically won, and in most cases undisturbed nights are ultimately arrived at. When it is not possible to get the child to wake as the result of sensation from his bladder, an alternative is to have him awaked at certain fixed hours for the purpose of making water. This is generally best accomplished by post-hypnotic suggestion, and is probably not made any easier to accomplish by electrical treatment, which latter aims at increasing the intensity of the natural call.

Internal Application of Electrical Methods.

Internal methods of electrical application are unpleasant and sometimes even painful. In unskilled hands they may be dangerous. The simplest method is to introduce a metal bougie into the bladder and pass a faradic current through it up to the patient's limit of tolerance. The risks are no more than such as are involved when any metallic instrument is passed into the bladder. A second method is to fill the bladder with a weak solution of zinc sulphate and pass into the bladder a rubber catheter containing a wire of soft metal. Care must be taken that the metal does not at any point come into contact with the wall of the bladder or the urethra. A current of 10 to 15 milliamperes is then passed for 10 minutes, the wire being positive; a pad is placed under the buttocks to form the negative pole. This proceeding may be repeated every other day for a fortnight.

The above methods increase sensibility as well as tone. They ultimately produce a certain amount of soreness which may aid in stimulating the patient's attention. But the action differs from that resulting from the mere introduction of an irritating solution into the bladder. I have seen cases of the latter in which the reaction was very severe, causing the patient to wake up to make water with pain and tribulation for days and even weeks; yet, ultimately, the incontinence was not even benefited.

Prognosis.

As to prognosis, on the whole, the cases in which the trouble comes on in apparently healthy children at the age of 4 or 5 are the most difficult to cure; but it should be possible to get a satisfactory result in at least 50 per cent. of such cases, even when various other methods have failed. The backward child, physically and mentally underdeveloped, benefits in a remarkable manner from the general effects of electricity, unless there is some actual congenital defect. The cure of the incontinence may, however, be delayed—the child has first to be brought to a stage of mental development where he can coöperate with the physician. The change in the physical and mental outlook of such little patients after a few weeks' treatment is often most gratifying to their friends and relations.

The time required to effect a cure in a favourable case is about a month, the patient being seen four or five days a week. A case which is definitely benefited but not cured in four weeks may require a further month to banish the trouble. On the other hand, if no improvement takes place in a month, it is best to have the case treated by hypnosis, either alone, or in combination with some electrical procedure which has not previously been used. It should not be forgotten, however, that the good effects of electrical treatment are sometimes a little delayed, and I have known several cases of boys who seemed little better at the time, yet proved to be greatly benefited after their return to school.

Incontinence occasionally follows an attack of infantile paralysis, the statements found in some text-books to the contrary notwithstanding. It is usually amenable to electrical methods and, when banished, the result is lasting.

Incontinence and Progressive Spinal Disease.

The case of incontinence occurring in the course of progressive diseases of the spinal cord—e.g., disseminated sclerosis—is somewhat different. It is impossible here to bring about a permanent cure; nevertheless, the sufferer should not be denied assistance, as a remission for several months can be secured by a few weeks' treatment; and such short courses can be repeated more than once with equally good effects. Besides the usual electrical technique X rays should be applied to the spine. I have personal knowledge of a patient suffering from disseminated sclerosis who has been kept comfortable as regards incontinence for nearly eight years, during which he has had seven courses of electricity and X rays, each of about four weeks' duration. This is an exception; but instances in which the incontinence has been kept at bay for three to four years are not uncommon. The urinary symptoms are often more distressing to the patient than the paralysis itself.

Percentage of Cures to be Expected.

To return for a moment, in conclusion, to nocturnal incontinence. Not every case can be cured by electricity—or for that matter, by any known methods. At the Cambridge Hospital, Aldershot, during the war, we worked out statistics for several hundred cases, and found that 65 per cent. were cured—i.e., they were reported as free from trouble a month after their return to their regiments. But these patients were all otherwise well-developed lads of between 19 and 20. Taking all types of patients, at all ages—which in my private practice have ranged from 3½ to 27—the percentage of cures to be counted on is over 50, but probably less than 60. This is a conservative estimate. One's results improve with experience, and, without being unduly optimistic, it is permissible to expect that in future it will be possible to attain success in three out of every four such cases.

SQUINT:

THE QUESTION OF EARLY OPERATION.

By W. B. INGLIS POLLOCK, F.R.F.P.S., GLASG.,
EXTRA SURGEON, GLASGOW EYE INFIRMARY; OPHTHALMIC SURGEON, AYR COUNTY HOSPITAL.

DURING recent years a number of papers have appeared upon the treatment of strabismus convergens and divergens, and several discussions have taken place at ophthalmic meetings, especially in America, upon this subject. There has been a general consensus of opinion that untreated squint produces, in a large number of cases, amblyopia, or blindness in the squinting eye, so-called amblyopia ex anopsiâ. This practical unanimity of opinion, notwithstanding Poulard,[1] has been reached mainly since the publication of the valuable researches of Mr. Claud Worth,[2] who was almost the first to measure accurately the visual acuity of young children immediately after the onset of the strabismus.

He has been able to demonstrate that amblyopia ex anopsiâ is almost entirely due to the convergent squint of childhood by showing that cases in which at the onset the vision of both eyes was normal, or nearly normal, when left untreated for two or three years returned with the squinting eye amblyopic or nearly blind. Prior to his time the accepted view was that the amblyopia preceded the squint, and was partly the cause of it. The amblyopia ex anopsiâ which follows squint varies generally between 6/24 and 0·5/60, and usually means complete inability to read ordinary type. When the vision is improved by glasses it is the defect which cannot be corrected which is called amblyopia ex anopsiâ. This form of amblyopia develops, as its name implies, from want of use. The squinting child would see double if he used both eyes. The child unconsciously suppresses the image of the squinting eye and does not use it, so that the vision in it is more or less lost. Diplopia may be elicited by special tests in recent cases. It is the same as if we bound up the arm of a child for months and years. It would waste and atrophy. If we bandage the eye of a young child for months it will also be found to become amblyopic; but adults do not lose the vision of an eye by prolonged occlusion.

The earlier that a convergent squint commences in childhood the greater is the degree of the amblyopia. Amblyopia is also increased by the duration of the squint; it does not, as a rule, occur when the squint commences *after* 7 years of age. At least, I do not recall having seen a case of it in which the strabismus had come on after that age, but when strabismus convergens develops under 3 years of age the squinting eye is almost certain to become amblyopic or blind. The only exceptions are when the squint is alternating, in which case the vision remains good in both eyes, or when the vision is saved by training the squinting eye, with or without occlusion of the good eye. These cases, however, are exceptional when the squint develops before 3 years of age. When the onset is between 3 and 6 years of age there is still great danger of amblyopia developing in the squinting eye, but it is more easily prevented by non-operative methods of treatment. The rate at which amblyopia develops varies in these cases, but I have seen several instances where it has come on within a period of from four to six months. I have observed amblyopia develop in a child's good eye which was being occluded for the sake of bringing back the vision to the squinting eye, but the vision recovered after removing the occlusive bandage. The younger the child the more rapidly the amblyopia develops.

Method of Testing Vision.

In testing the vision of these young children one must gain their confidence. My usual plan is to cover the squinting eye and to teach them the names of the different objects on the test types, on which are represented horses, pails, barrows, flags, &c. After the child gets to know the names of the different test objects the parent is told to cover the good eye completely with a handkerchief so as to make sure that the child is not seeing with it. The child now knows the names of the objects on the test type, but has not had time to remember their order. He will often show his blindness by giving the wrong names when the squinting eye is thus tested. He must be brought nearer and nearer, at the same time taking great care to prevent his seeing with the good eye, until he is able to state correctly the name of the largest object. A child sometimes cannot even name, with the amblyopic eye, the largest object at a distance of half a metre. Transfer the cover then to the defective eye, and you can at once demonstrate to the parents how good the sight is in the other eye, because generally they attribute the defect of the blind eye to ignorance and not to defective sight. The vision should be tested before the use of atropin, but if the child becomes irritable it is best to repeat the examination a week later, and try again to gain the confidence of the child. It is remarkable how quickly they become accustomed to the various steps of the examination.

The refraction should be tested after the use of atropin for children or homatropin for adults, while the fields of fixation and the positive and negative ranges of convergence should be investigated as pointed out by Mr. Freeland Fergus.[3]

Treatment.

Non-operative.—For a number of years I attempted to cure the concomitant strabismus convergens and strabismus divergens of childhood by non-operative methods, such as occlusion of the good eye and prism training. Each case was examined for astigmatism, and suitable glasses were prescribed. I always attempted to give as high a value as possible to the hypermetropic element in convergent cases, which means in myopic convergent cases the weakest spherical element possible. In divergent cases, on the other hand, the lowest hypermetropic element was taken, and if the eyes were short-sighted the strongest myopic glass which could be safely prescribed was employed. After the glasses were prescribed the children were kept on atropin for a prolonged period in the convergent cases, while the good eye was occluded more or less constantly. To private patients I lent Priestley-Smith's tubes or prescribed prisms for training purposes. These methods always took a considerable time, and even after a course of 6 or 12 months they frequently failed. I was therefore driven more and more to operate for the treatment of squint. It is unnecessary to give the history of such cases.

Operative.—In former times it was said that one should wait until the child was 15 years of age before operating upon the squint. When it became generally recognised that by this time the squinting eye was often hopelessly blind and practically useless it was suggested that the operation should be performed at 7 years of age. However, I found that that age was far too late in many cases. A 7-year old child is often brought for treatment who has had two or three pairs of glasses and is still squinting, while the squinting eye is nearly blind.

Kearney,[4] in a recent article, states that he has also been driven to operate in most cases of strabismus convergens and I would agree with all he says on the subject, but I would urge that the operation should be undertaken earlier. Amblyopia may develop rapidly. I have seen it come on in the course of six months, and on the other hand, I have seen it disappear equally rapidly after a successful operation done for a patient who was 4 years of age.

The following cases show what can be done by early operation and training of the amblyopic eye.

CASE 1.—Jan. 21st, 1919: V. U., a girl aged 3 years, a patient of the late Dr. Willis, of Strathaven. Strabismus convergens of right eye. Angle 50°. Duration four months. Illiterate type. V.R. 6/36; V.L. 6/12. Ordered atropin to both eyes. 28th: Retinoscopy:

$$\text{R.}\ \begin{matrix}+4.5\\+7.5\end{matrix}\qquad\qquad \text{L.}\ \begin{matrix}+5.5\\+8.5\end{matrix}$$

Ophthalmometer, R. and L. 3·5 D. ax. 90°. Feb. 4th: V.R. +3 D. Sph. +3 D. Cyl. ax. 90° = 6/36. V.L. +4 D. Sph. +1·5 D. Cyl. ax. 90° = 6/12. Ordered R +2·75 D. Sph. +3 D. Cyl. ax. 90°. L. +3·5 D. Sph. +1·5 D. Cyl. ax. 90°. To keep left occluded all day. April 7th: Advised operation. Oct. 10th: R. Advancement rectus externus with modified tenotomy rectus internus. 24th: Straight. March 29th, 1920: V.R. +4 D. Sph. +4 D. Cyl. ax. 90° = 6/12, 1 letter. V.L. +4 D. Sph. +2 D. Cyl. ax. 90° = 6/6 letters. Straight. No return of the squint.

CASE 2.—August 5th, 1918: R. W., a boy aged 4½ years. A patient of Dr. D. J. Graham, of Edinburgh. Strabismus convergens of left eye. Angle 35°. Duration two years. Illiterate type. V.R. 6/12, V.L. 0·5/60. Ordered atropin to both eyes and to cover right eye two hours daily. Oct. 10th: Advised operation. Stop atropin. Nov. 27th: L. Advancement rectus externus with modified tenotomy rectus internus. Dec. 14th: Stitches removed. R. converging 10°. Jan. 28th, 1919: R. Advancement rectus externus with modified tenotomy rectus internus. April 3rd: Straight V.R. 6/18, L. 6/24. Sept. 4th: Straight V.R. 6/12, L. 6/9. Nov. 15th, 1920: Straight, with gl. V.R. 6/6, with gl. L. 6/6. Stop occlusion of right eye.

CASE 3.—Oct. 28th, 1918: W. R. W., a boy aged 8 years (elder brother of Case 2). Strabismus convergens of right eye. Angle 40°. Duration four years. Has had glasses +1 D. Sph. all the time, but they have done no good. V.R. 6/24, V.L. 6/6. Advised operation. Nov. 27th: R. Advancement rectus externus with simple tenotomy rectus internus. Dec. 14th: Stitches removed. April 3rd, 1919: Straight V.R. 6/6, 2 letters. V.L. 6/3, 1 letter. May 21st: R. Converging 5°. V.R. 6/9. V.L. 6/3, 1 letter. June 11th: L. Advancement rectus externus. Sept. 4th: Straight R. 6/6, 4 letters, L. 6/3. Jan. 13th, 1920: Straight R. 6/6, L. 6/3.

CASE 4.—Nov. 10th, 1919: J. A. M., a boy aged 7 years. Strabismus convergens of left eye. Angle 35°–45°. Duration 3½ years. V.R. 6/6. With glasses 6/6. V.L. 6/36. With glasses 6/18. Advised operation. 26th: L. Advancement rectus externus. Dec. 9th: R. Advancement rectus externus. Jan. 28th, 1920: L. Still converging. April 9th: L. Re-advancement rectus externus with modified tenotomy rectus internus. 26th:

$$\text{R.}\ \begin{matrix}+3\\+3{\cdot}5\end{matrix}\qquad\qquad \text{L.}\ \begin{matrix}+1{\cdot}5\\+4{\cdot}5.\end{matrix}$$

Ophthalmometer, R. 1 D. ax. 90°. L. 1·5 D. ax. 90°. May 18th: V.R. +1·5 D. Sph. +0·5 D. Cyl. ax. 90° = 6/5. V.L. +1 D. Sph. +2·5 D. Cyl. ax. 90° = 6/9, 3 letters. Ordered above lenses, and atropin to right eye. Feb. 2nd, 1921: V.R. (dilated pupil) with above glasses, 6/12. V.L. (active pupil) 6/24. With glasses, 6/9, 2 letters. No return of the squint.

CASE 5.—Nov. 28th, 1919: J. I., a boy aged 5½ years. A patient of Dr. Robertson, of Motherwell. Strabismus convergens of the left eye of three months' duration. V.R. 6/9. V.L. 4/60. Atropin drops to both eyes. Dec. 3rd:

R. $\substack{+4{\cdot}5 \\ +5}$ L. $\substack{+4{\cdot}5 \\ +5{\cdot}5.}$

Ophthalmometer, R. 1·5 ax. 90°. L. 2·5 ax. 90°. V.R.+3 D. Sph.+0·5 D. Cyl. ax. 90°=6/9. V.L.+3 D. Sph.+1 D. Cyl. ax. 90°=6/60. Advised operation. Jan. 31st, 1920: L. Advancement rectus externus. Feb. 14th: R. Advancement rectus externus. 23rd: L. Modified tenotomy rectus internus. March 26th: Straight. Ordered: R.+2 D. Sph.+0·5 D. Cyl. ax. 90°. L.+2 D. Sph.+1 D. Cyl. ax. 90°. March 23rd, 1921: V.R. 6/6. V.L. 6/24. Glasses no improvement. This patient has had no special training by occluding the right eye, but he is now again instructed to cover the right eye two hours daily.

Recovery of Vision in the Squinting Eye.

The table gives the visual acuity of the squinting eye, after correction with glasses if they were necessary, both before operation and at the latest date on which I have seen the patients after operation. The last column gives the duration of the occlusion of the non-squinting eye, in these cases of monocular strabismus. It will be seen that there was no occlusion of the good eye in Cases 3 and 5.

Case.	Before operation.	After operation.	Occlusion of good eye.
1	6/36	6/12	Half a day for 2 months.
2	0·5/60	6/6	2 hours daily for 15 months.
3	6/24	6/6	None.
4	6/18	6/9	Half a day for 12 months.
5	6/60	6/24	None.

Remarks.

Case 3 was 8 years of age when he first came, and the squint had been present for four years, during all of which time he had worn glasses. After the operation he discarded his spectacles. They were +1 D. spheres, and had been prescribed by another ophthalmic surgeon. I told the boy to wear them if he had pain in his eyes while reading, but they have not been necessary.

Case 5 was 5¾ years of age, and the squint had been present for three years. The improvement in vision, as above, was found a year after the operation, although no training had been undertaken at all. Instructions have now again been given to occlude the good eye for two hours daily, and to report in three months time. The other three cases have all had more or less continuous occlusion of the good eye.

Case 1 was 3 years of age, and the squint had been present for four months. After the operation she stopped attending and was lost sight of for four years. The occlusion had only been used for two months, and the improvement in vision was therefore almost entirely due to the result of the operation.

Case 2 had never been treated with glasses, and his vision made remarkable improvement from the date of operation. When he first came he was unable to recognise the largest letter except at a distance of ½ a metre. He was 4½ years of age, and the squint had been present for two years. He had occlusion of the good eye for two hours daily for about 15 months, and at the end of that time the vision had improved from 0·5/60 to 6/9. Recently he has been ordered glasses, and with these there was a further improvement to 6/6 in both eyes separately.

Case 4 was 7 years of age and had the squint for 3½ years. After operation the vision of the squinting eye had improved from 6/18 to 6/9. He has had atropin in the good eye, as well as occlusion, but the vision of the squinting eye still remains slightly defective. This is probably due to the fact that there was great difficulty in persuading the boy to keep the good eye occluded, and he constantly pushed the patch aside from the right eye. He has not yet been able to reach more than 6/9.

It will be seen, therefore, that each of the cases show an improvement in the vision of the squinting eye after the operation, two of them being without any occlusion of the good eye, while the remarkable recovery of Case 2 was due to the operation as much as to the occlusion of the good eye. If a child of 1 to 3 years is going to lose the sight of one eye, why should it be refused an operation, when by such an operation amblyopia may be prevented. The position which I take up is that the operation should be done within a reasonably short period after the appearance of the squint.

Children are frequently brought to us when the squint has just appeared. If we then give them glasses the parents are satisfied and they disappear, and nothing further is done. The glasses are often lost, and when they come back we find that the squinting eye is practically blind. Would it not be far better to perform the operation when the children are first brought to us? If the eyes are put straight it is the best chance for recovery of vision in the squinting eye. The earlier the operation is done the better, because there is a far greater tendency to the recovery of function. If the operation is delayed there is less likelihood of the disappearance of the amblyopia, and, indeed, it is not to be expected after the age of 15 or 20.

The one condition is that the squinting eye be put straight, both for near and for distance. The operation is useless unless the eye is made absolutely straight. If there is the slightest squint still present there is no recovery of function, because the child would again see double, and therefore still suppress the vision of the squinting eye. It has been said that the same may be done by non-operative methods, including glasses, but it is well known that the squint often recurs with the glasses. I would go further. The squint must be put so straight by operation that it is independent of glasses, unless they are required for refractive errors. It is a pure waste of time trying non-operative methods if we have to fall back on operation at the end.

Objections.

One objection that has been raised against early operation is that if the squint is left alone a certain number of cases come straight. This point, of course, is known to everyone, and has been found recently in the recruiting stations. Dr. Clarence Löeb[5] has pointed out that the number of men with one eye amblyopic made a fairly considerable percentage of the returns from the eye examinations of recruits, whereas adult men with a convergent squint were in a much smaller percentage. He suggested that if the amblyopia caused the squint, the ratio should be in the inverse. The cases which come straight without operation in my experience are nearly always those which have become amblyopic in the squinting eye. In such a case, had it been operated on within a short period of the onset of the squint the amblyopia would have been prevented.

The second objection which has been raised is that some parents prefer their children's eyes to be put straight by glasses. This seems often to be because the parents themselves have already worn glasses all their lives and consider that nothing better can be hoped for their children. There seems also to be a widespread belief in the uselessness of strabismus operation, apparently due to the non-success of the earlier methods of operating. If there is slight astigmatism and low refractive error, I advise that the patient should have an operation and leave off the glasses. If the refractive error is of a medium amount or higher, I tell the patient to wear the glasses outside when they experience the necessity for them, and to keep them as much as possible for near work. If the patient has been put straight by operation then glasses should not be necessary to keep him straight.

THE TREATMENT OF CASES OF SYPHILIS HAVING A PERSISTENT POSITIVE WASSERMANN REACTION.

By C. F. MARSHALL, M.D., M.Sc. Vict., F.R.C.S. Eng.;

AND

A. G. SHERA, M.D., B.Ch. Cantab., M.R.C.S.,
PATHOLOGIST TO THE PRINCESS ALICE HOSPITAL, EASTBOURNE; LATE PATHOLOGIST TO THE BRITISH RED CROSS HOSPITAL, NETLEY.

Cases of syphilis with a positive Wassermann reaction persisting in spite of treatment may be provisionally divided into two categories: (1) those in which clinical symptoms also persist or continue to recur; (2) those in which the positive reaction is the only sign, clinical symptoms having been absent for some considerable time. It is obvious that cases belonging to the first category require further treatment; but the procedure to adopt in cases belonging to the second category is not so easy to decide.

In the present state of our knowledge this question cannot be decided by statistics, for the Wassermann reaction is of too recent introduction for us to know the ultimate fate of such cases. We do not yet know how long the reaction may remain positive, nor whether it tends to become negative after a lapse of time. Nor do we yet know whether it is these cases with persistent positive reactions which ultimately develop tabes, general paralysis, and other late manifestations. To decide this question we should require statistics of the Wassermann reaction 10 or 20 years hence in patients who have been treated during the last 10 years. All we know at present is that the reaction may remain positive in spite of repeated and intensive courses of treatment, and also that it may become negative in the absence of treatment.

Cause of Reaction—Generally Accepted View.

The advisability or not of giving further treatment to cases with a persistent positive reaction, but no clinical symptoms, depends upon the real nature and significance of the reaction itself, and whether a positive reaction always indicates the presence of living spirochætes or not. The view now generally accepted is that the reaction is caused by substances of histogenetic (katabolic) and not microbial origin, and it is not inconceivable that these substances may continue to be formed for some time after the death of the spirochætes which originally gave rise to their formation. If a patient with a persistent reaction could be reinfected with syphilis, this would decide the question; because, for true reinfection (as distinguished from superinfection) to take place all the spirochætes of the first infection must be dead. So far as we know, no such case has been recorded; as a rule, recent blood tests have not been made in cases of true reinfection.

Problem of Persistent Positive Reaction.

If a positive reaction always signifies active spirochætosis further treatment is evidently indicated, but if it may be due to the continued formation of katabolic tissue products in the absence of spirochætes further treatment is obviously contra-indicated, if no symptoms are present. Assuming that the first interpretation of the reaction is correct, when the reaction remains positive in spite of repetition of the same courses of treatment, it would appear advisable to change the therapeutic methods. The majority of cases with persistent positive reactions, including most of those in the table opposite, have been treated with the usual courses consisting of intravenous injection of arsenical compounds and intramuscular injection of mercurial cream. This method is strong in arsenic but rather weak in mercury. It would be interesting to find whether an increase in the intensity of the mercurial factor would reduce the number of persistent reactions.

Effect of Sulphur.

The effect of sulphur is another point worthy of investigation. Sulphur, which was formerly much used in the treatment of syphilis, has lately fallen into disuse, but has been revived by McDonagh in the form of intramine. Case 10 in our table is suggestive in this connexion. This patient had been treated with two courses of intravenous injections of neosalvarsan and mercury. When seen by us there were no signs of syphilis, but the reaction was found to be strongly positive. Further treatment by mercury and iodides was not tolerated. Sulphur was then given, and the reaction is now negative. Although it is impossible to generalise from a single case, the administration of sulphur in these cases seems worth a trial.

Conclusions.

1. We are of opinion that the possibility of the Wassermann reaction remaining positive in the absence of active spirochætosis has not yet been disproved. But, as it is equally impossible to disprove the contrary hypothesis, it is best in actual practice to regard a patient with a persistent positive reaction as one who is not definitely cured and as a subject for further observation and possibly further treatment.

2. We consider that a persistent positive reaction is not, by itself, sufficient evidence to decide the question of further treatment, and that we should be guided equally by the clinical progress of the case, the nature of the former symptoms, and the intensity and duration of previous treatment. If clinical symptoms have been present comparatively recently (say, during the last 12 months), we hold that further treatment is advisable; but if symptoms have been absent for more than a year, that the advisability or not of further treatment should depend chiefly upon the clinical course of the case.

3. If further treatment is decided upon, we think that this should differ materially from that given previously. We suggest that sulphur should form part of this treatment without venturing on any hypothesis to explain its possible action.

Cases with Persistent + Reaction but no Symptoms.

No.	Stage of disease.	Treatment received.	W.R.	Remarks.
1	S.	Two courses.*	+	Recommended further treatment.
2	S.	Three "	+ + +	
3	T.	Two "	+	Disappeared.
4	T.	One course.	+ + + +	Receiving further treatment.
5	T.	Treated 5 years ago; method unknown.	+	
6	T.	One course.	+ + +	Disappeared.
7	T.	Two courses.	+	
8	T.	One course.	+	
9	T.	One course of galyl and mercury.	+ + + +	Before treatment reaction only +.
10	T.	Several intensive courses of neosalvarsan and mercury.	+ + + +	Treatment by mercury for short time.‡
11	T.	Treated 20 years ago with mercury.	+ + + +	Recommended further treatment.
12	C.	Two courses.	+ +	

* One course as a rule consisted of 1·5 g. N.A.B. and 6 gr. Hg.
‡ Then sulphur, after which reaction became negative.
+ = Weakly positive. + + = Positive. + + + = Strongly positive. + + + + = Very strongly positive.
S., secondary. T., tertiary. C., congenital.

The method used was that described by one of us (A. G. S.) in Marshall and Ffrench's "Syphilis and Venereal Diseases" (1921), wherein the complement was kept constant and the antigen varied.

Sterilisation and Washing of Infectious Linen is undertaken by Messrs. W. G. Lacy and Co., Ltd., St. John's Wharf, Carnwath-road, Fulham, London, S.W.6.

Clinical Notes:

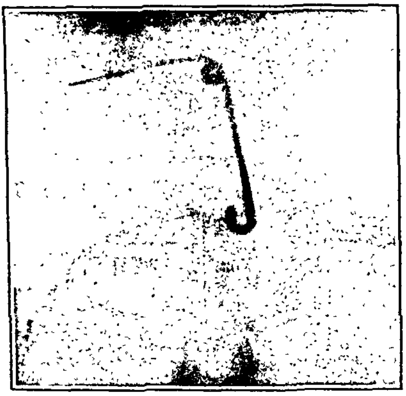
MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

AN UNUSUAL CASE OF A FOREIGN BODY IN THE ŒSOPHAGUS FOR NINE MONTHS.

By CHARLES H. CARROLL, M.R.C.S., L.R.C.P.LOND.

IN May, 1918, when house surgeon to the ear, nose, and throat department of the London Hospital, I was consulted by a woman who brought her baby boy, aged 15 months, to the hospital, suffering from what appeared to be a superficial ulcer on the neck, which she stated had existed for some considerable time past, healing and breaking down in turn. On examining the child's neck and removing the scab from the ulcer, I felt a "pin point" projecting through the centre of the wound.

The child was admitted for investigation of its condition and X ray examination, the result of which is disclosed in the accompanying X ray photo. The mother, on being shown the photo, at once said: "That is the safety-brooch which I gave baby nine months ago in his cot to play with, and it was lost." I had no doubt as to her statement being correct.



Radiogram showing safety-brooch in œsophagus.

Under general anæsthesia, Mr. Norman Patterson, surgeon to the department, passed an œsophagoscope and cut the pin, distal to the joint; the portion projecting through the soft tissues of the neck was removed by that route and the major part through the œsophagoscope. The child was discharged home in a few days none the worse for its experience.

The pin, on examination, proved to be a brass safety-brooch with a flat bar; and the point of interest is the fact that a baby should be able to put up with so formidable a foreign body in its œsophagus for so long a time without any apparent symptoms of dysphagia or discomfort.

A CASE OF LOCKED TWINS.

By DENIS V. MURPHY, M.B., B.CH. N.U.I.,
DISTRICT MEDICAL OFFICER, QUEEN CHARLOTTE'S LYING-IN HOSPITAL, N.W.

LOCKED twins is a very rare condition; Munro Kerr, in his "Operative Midwifery," states that V. Braun only found instances of two such cases in the 90,000 recorded at the Vienna clinic. Further, he states that knotting of the cords in twin pregnancy is also very rare, and illustrates this condition by a photograph of twin cords knotted twice; he says also that such knots lead to fœtal death. The following case is therefore of interest, as both these conditions were present at the same time and without fœtal death.

On April 25th last I was called to see Mrs. V., aged 23, primipara. Membranes ruptured during sleep 38 hours previously, and the midwife sent as "presentation not made out, fœtus passing meconium."

Abdominally.—Fundus was broad, too big to contain a head, too hard for a breech, no ballottement elicited; uterus tended to be moulded on fœtus; fœtal back to the left anterior; fœtal heart heard at level of umbilicus to the left and soft part made out engaged in the brim.

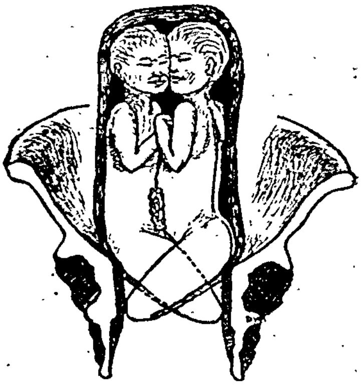


FIG. 1.—Presentation (diagrammatic) at first P.V. examination.

Per Vaginam, pelvis was full of a mass of "small parts" so tightly wedged together that examining fingers were unable to sweep around the mass. A knee was recognised, and after some force was used a foot was brought to the vulva; another foot was found then just inside and brought to the surface. No advance being made with the next pain, the fingers were again introduced, and to my astonishment found two more feet lying loose in the hollow of the sacrum, which followed my fingers to the vaginal orifice as I withdrew them. There were now four feet showing at the vulva, all moving voluntarily. One fœtus was now seen to be lying in the L.S.A. position and the other in the R.S.A. position. An attempt was made to push up the posterior fœtus, but this had to be given up as there was no upward movement. Traction was now made on legs of the anterior fœtus, the buttocks of the posterior being kept up by a hand inside vagina. The anterior fœtus moved downwards for about 6 inches and stopped; the cord was palpated and found pulseless and the arms were extended, these latter were now brought directly downwards, much force having to be used. The head now locked, chin on the symphysis of the other fœtus and occiput on the mother's pubis. By applying two fingers to back of neck and pushing in the direction of the sacrum and rotating the head backwards with a hand externally, the head passed the brim and delivery was effected. Cord being taut, was cut and clamped. Other child followed in 10 minutes—both were dead. Placenta came away 10 minutes later. There was no post-partum hæmorrhage and patient made an uneventful recovery.

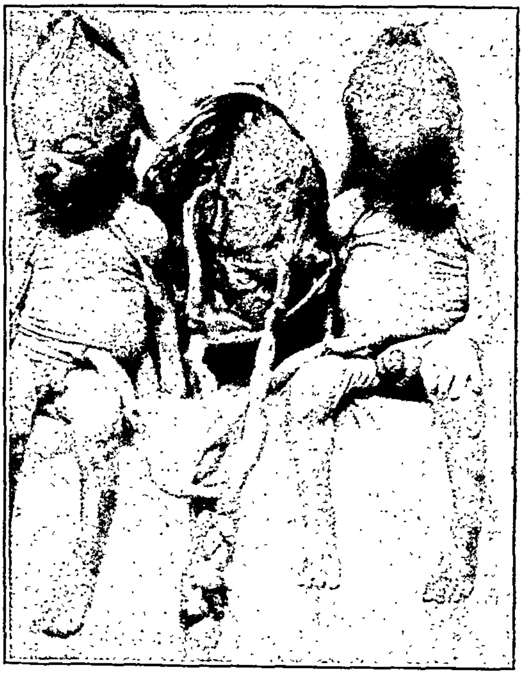

FIG. 2.—The fœtuses with the knotted cord. The uppermost knots being unravelled when fixing specimen for photographer.

Presentation.—"Locking" or impaction of twins due to descent of two breeches, is not described in the text-books. In this case there was clearly a double knee presentation (Fig. 1) and impaction resulting as both fœtuses entered the brim together. The cause of the fœtuses presenting together was evidently due to the shortening of the cords by the knotting. The liquor amnii having drained away for 38 hours caused the uterus to tend further to keep the fœtuses together during the first stage. The fœtal heads were much flattened on one side where they were in apposition. Uniovular twins, males, 17½ inches and 17 inches long; weight, 3 lb. 8 oz. and 3 lb. 6 oz., about 34 weeks maturity.

Cords.—The centres of both cords were looped, coiled, and knotted together into an elongated mass about 7 inches long, which lay at right-angles to the cords (Fig. 2). The cords show at least eight distinct knots, and at the free end of this mass are very tight. It is of interest that both fœtuses were alive before delivery, despite this condition.

I have to thank Mr. Leonard Phillips, obstetric surgeon to out-patients, Queen Charlotte's Hospital, for permission to publish this case. My thanks are also due to Mr. H. H. Gellert, house surgeon of the Samaritan Hospital, for his kindness in taking the accompanying photograph and to the district superintendent, Miss Rodmell, for her valuable assistance during the course of this case.

CASE OF ALUMINIUM POISONING.

BY JOHN SPOFFORTH, L.R.C.P.EDIN., M.R.C.S.ENG.

I WAS recently called to see a man, aged 40, who was then employed at a firm of metalworkers. He was in a state of great exhaustion and suffering from very severe and persistent vomiting. The pulse was slow and irregular. I suspected metallic poisoning and later sent a specimen of his urine to Messrs. Thomas, Bourlet, and Newman, analytical chemists, who reported that it contained a large amount of aluminium, also of phosphates. The patient said that he had been dipping red-hot metal articles, contained in an aluminium holder, into concentrated nitric acid. Aluminium produces a rather slow intoxication. In this case it caused loss of memory, tremor, jerking movements and impaired coördination. There was also chronic constipation and incontinence of urine.

Richborough-road, Cricklewood, N.W.

A CASE OF RECKLINGHAUSEN'S DISEASE.

BY F. McG. LOUGHNANE, F.R.C.S. ENG.,

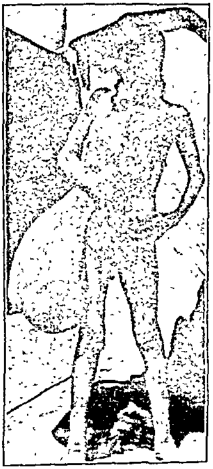
HONORARY SURGEON, ST. MARY'S HOSPITAL, PLAISTOW.

THE patient, an Arab, I saw when in Mesopotamia. He had been found in a palm grove, where apparently he had been deserted; he said his age was 25 years, but he appeared to be about 50. His history was difficult to interpret accurately, but as far as one could gather he had had lumps on his body for as long as he could remember; no other member of his family or village had been similarly afflicted.

All over his trunk, limbs, and head he was covered with multiple tumours of molluscum fibrosum, varying in size from a small pin's head to a Victoria plum, with the exception of one exceedingly large tumour hanging from the right loin, which on removal weighed 70 lb. The skin covering the tumour was thick and corrugated, inflamed in some parts, ulcerated and septic in others. On palpation it felt more or less semi-solid, and a fluid thrill was present. The tumour was about the size of a small sheep, and when standing the patient carried it under his arm. The base of the pedicle, with the patient lying down and the tumour extended, was 11 inches broad. The general condition of the patient was poor: he had a temperature of 101° F., was very emaciated and obviously suffering from toxæmia. He was kept under treatment for a few days so that he might withstand an operation with greater safety, but as he showed no improvement I decided to operate at once, hoping his life would be saved by the removal of a great source of toxæmia, and to fit him to earn a living instead of being dependent on the chance alms of a casual passer-by.

Chloroform anæsthesia was given by Captain W. H. Dye, and I was assisted at the operation by Captain A. J. McDonnell. An hour previous to the operation patient had been given a rectal saline with brandy. A separate table was required for the tumour to rest on. The operation was rather prolonged, 70 minutes, which was unavoidable for two reasons—first, the tumour had dragged into itself a portion of the abdominal wall, which here was very thin, necessitating careful separation to avoid opening into the peritoneal cavity, for the separating muscle layer was almost non-existent; and secondly, there was a great risk of hæmorrhage, so the vessels had to be identified before division. The tumour was very vascular. There were a large number of vessels running irregularly through the pedicle, and many of the veins were the size of the average common femoral vein. Despite all precautions there was a fair amount of hæmorrhage, though not more than occurs in many a breast operation. Patient collapsed towards the end of the operation, and saline was given intravenously and subcutaneously, but he died two hours later.

On cutting open the tumour later it was seen to consist of a large amount of fat, running through which fairly large nerve strands were clearly visible. The vessels, especially the veins, were large and numerous. In places the tumour was pulpy and undergoing degeneration. Suppuration had extended some inches deep to the ulcerated areas.



The patient standing, showing the large tumour amputated from patient's side and several smaller tumours on body and limbs.

Death was due to three causes: (1) Debilitated condition of the patient, (2) shock, and (3) hæmorrhage, not free, but in the amount of blood necessarily withdrawn from the body by removal of a tumour weighing 5 stones.

Remarks.

The question of shock is an interesting one, for it is well known that the nearer to the trunk a limb is amputated the greater the shock, due to the fact that large nerve trunks and vessels are implicated. In this case an exceedingly large tumour was amputated from the trunk itself, a tumour both very vascular and certainly containing a very large amount of nerve tissue.

The same patient in resting position.

For the accompanying photographs I am indebted to Captain McDonnell for the negatives, and to Captain C. G. Whorlow for the prints.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF LARYNGOLOGY.

The summer meeting of this Section of the Royal Society of Medicine was held on June 2nd and 3rd, Dr. W. Jobson Horne occupying the chair.

Complete Tonsillectomy as a Routine Operation.

Mr. Mark Hovell read a paper on this subject. He said that during the last few years the practice had sprung up of systematically enucleating all tonsils which were found to be enlarged, quite irrespective of the cause of such enlargement; hence the mere slicing of a portion of the redundant tonsil, leaving the remainder behind, had been largely criticised and regarded as an incomplete procedure. He reminded members that not every enlarged tonsil was diseased; in children especially such hypertrophy was a result of nasal obstruction, and when free nasal respiration had been restored the tonsillar tissue contracted again. Therefore, he contended that in such cases removal of the projecting portion of tonsil while exerting counter-pressure from outside and the application of astringents was all that was needed. He criticised the habit of rapid operating under nitrous oxide gas, no attempt being made to ascertain the condition of the posterior extremity of the inferior turbinate body. In deciding to stitch the pillars of the fauces it should be remembered that the movements of the soft palate were thereby curtailed. Hæmorrhage, also, after complete enucleation, might be very serious, and he knew of several deaths from it, and the later singing voice was liable to be jeopardised by the radical procedure.—Dr. D. Aitken confirmed Mr. Hovell's contentions, especially concerning the bad effect on the voice following the complete enucleation.—Mr. W. Rose took the opposite view to Mr. Hovell's, urging the complete operation. Not merely was the partial operation inadequate, in his opinion, but in some cases its performance had been the starting-point of repeated attacks of tonsillitis. He agreed that the scarring following tonsillectomy in some cases resulted in impairment of the voice.

Mr. Jefferson Faulder did not agree that mere enlargement of tonsil had been regarded as an indication for total removal. When there was mere enlargement, with no other symptom, it sufficed to remove the enlargement. He quoted an intimate case in which partial procedures led to a long course of trouble and inconvenience.—Sir William Milligan said he regarded a hypertrophied tonsil as a diseased one, and septic tonsils should be subjected to complete tonsillectomy, to entirely get rid of the crypts. By mere tonsillotomy the crypts were all opened up and were the ready receptacles of septic and other foreign material from the mouth. Before any slicing procedure, the condition of the mouth, especially the teeth, should be investigated. He deprecated hurry in the operation. He did not remember more than three of his cases in which suture had had to be performed.—Mr. Wright (Bristol) said cases in which removal of tonsils was necessary could be divided into two classes: (1) those in which the tonsils were freely movable on the pharyngeal wall, in which the complete removal could be done as easily and be as free from risk as taking away a portion; (2) those in which the tonsil was adherent to the pharyngeal wall owing to recurring attacks of peritonsillar inflammation. Though more difficult in these, the complete operation was the only reasonable one.—Mr. W. Stuart-Low took the opposite view to Mr. Hovell, and deprecated the public being led to believe that partial operation or medical measures sufficed.—Mr. F. H. Diggle agreed with what Sir William Milligan had said. He referred to his histological investigations of removed tonsils, and said he found in 75 cases five were definitely tuberculous. He knew no means of distinguishing these from ordinary chronic enlargements, for the five tuberculous cases had no enlarged glands. The tonsillar operation should be as thorough as any other surgical procedure.—Mr. J. F. O'Malley was also an advocate for complete removal, for none were called upon to operate on tonsils which were healthy. The larger number of cases of fatal or alarming hæmorrhage in the last 60 years occurred in the period when tonsillotomy was the chief operation; hæmorrhage was held by some to be more likely when a part of the tissue was left.—Dr. Burger (Amsterdam) said he had recommended and carried out tonsillectomy as the general operation for children. With regard to mortality, there was always a tendency for operators to report their best cases. For tonsillotomy he did not consider a general anæsthetic was needed in the case of children.—Mr. Douglas Guthrie referred to the class of case in which the enlargement wholly projected and there was no buried portion. For these not numerous cases tonsillotomy sufficed.—Mr. Herbert Tilley said he never used a guillotine for tonsils; he always did enucleation and dissection, and he agreed with Sir William Milligan.—Mr. Horgan said he used the guillotine, and that the scarring left after operations on the tonsil was due to over-instrumentation. He referred to the valuable work on the pathology of the tonsils by Mitchell, of Edinburgh.—Mr. Syme agreed with Sir William Milligan, and said there was need for a more exact diagnosis of these conditions, to determine which should be removed and which could safely be left, hoping for a return to a normal size.—The President thought the trend of the discussion had shown that a tonsillar case should either be left alone or tonsillectomy carried out. There was much to be said for that. Mere size of tonsil was not an indication for operation; the largest tonsil he had ever seen was in a man who made no complaint about himself; he had brought somebody else for treatment! If coincidently with enlarged tonsils cervical glands were palpable, that was an indication for removing the tonsil.—Mr. Hovell replied.

Operations on the Frontal Sinus.

Mr. Walter Howarth read a paper on this subject, remarking that only recently had thorough operations on the sinus become established, hence no single operation had become stereotyped. He believed the experience of an individual, if his cases were numerous enough, was a more valuable criterion than that of a group of operators. He had dealt with over 200 frontal sinus cases. He regarded the ethmoid as the key to the frontal sinus. With regard to the intranasal operation, the fronto-nasal duct could be enlarged so that it would admit the passage of a No. 15 bougie, and it was effected by removing the spur of bone which projected from the nasal process of the frontal bone. The opening could be maintained long enough to ensure a permanent cure of the sinus suppuration in a large number of cases. The more acute the stage, the more was the intranasal operation likely to be successful. In reference to the external operation, he said the Killian—which he did not perform—was founded on the fallacy that it was possible to completely obliterate the frontal sinus. Complicated sinuses were common, and the Killian operation was apt to leave dead spaces behind the bridge, along the ethmoid and elsewhere, which prevented satisfactory healing and might be a source of future danger. But why try to obliterate the cavity when it could be drained? The procedure he had adopted for eight years was to open the sinus just above the lacrymal groove and remove the floor, disturbing the mucous membrane as little as possible. He next dealt with the ethmoid, all the anterior cells being removed; this cavity was then joined to the frontal sinus by cutting through the ascending process of the superior maxilla and the nasal process of the frontal bone. There was no alteration in contour as a result of this, and the scar was so fine as to be almost invisible. It was a safe operation, as he had not lost a case, and he never regretted the day he had embarked on it.—Mr. HERBERT TILLEY said he had not done the Killian operation for six or seven years. Failure in so many operations on the frontal sinus was due to the fact that the operator so often overlooked the fact that an outlying orbito-ethmoidal cell was leaking into the floor of the frontal sinus, and what had been regarded as the floor of the sinus was really the roof of the orbito-ethmoidal cells.—Several other members took part in the discussion.

Site of Origin of Intrinsic Laryngeal Cancer.

Sir STCLAIR THOMSON read a contribution entitled "The Usual Site of Origin of Intrinsic Cancer of the Larynx as demonstrated at 50 Laryngo-Fissures." The series showed that malignant disease exhibited no preference for the posterior part of the vocal cord, although it had been so stated in text-books. The invasion of the neoplasm in the 50 cases was as follows:—

Limited to anterior third of cord	3	cases.
" middle third	7	"
" posterior cord	0	"
" anterior and middle together	16	"
" middle and posterior together	3	"
Occupying the whole cord	21	"

Expressed another way, the cancer invaded the anterior third in 39 cases, the middle third in 47 cases, the posterior third in 24. The growth was in the subglottic area in 13 of the cases, and more than 50 per cent. of the subglottic cases had died of recurrence. In every case, however limited the growth might be, the entire vocal cord *should be excised*.—The paper was discussed, and Sir STCLAIR THOMSON replied.

Paralysis of Vocal Cords in Cases of Malignant Breast Tumours.

Dr. LOGAN TURNER (Edinburgh) submitted an interesting contribution on this subject, based upon six cases he had seen in the last 12 years. Three were married women, three unmarried, and they were first seen for hoarseness, which had developed at varying periods after breast amputation for malignant disease, the average period between the two events having been 3½ years. In none of the cases had there been operation on the cervical glands, the question of trauma did not therefore arise. Two of them were cases of contralateral paralysis—i.e., the cord on the opposite side to that of the breast cancer was paralysed. By means of an epidiascopic demonstration he showed the mechanism of causation.

Diathermy in Inoperable Cancer.

Sir WILLIAM MILLIGAN gave a contribution on diathermy in inoperable pharyngeal and epi-laryngeal malignancy, its objectives and limitations, with a review of cases. He said that during six years he had made use of diathermy in even inoperable cases of malignant disease in the floor of the mouth, the tongue, the faucial pillars, the sinus pyriformis, and even in the hypo-pharynx. He found that in inoperable cases diathermy placed the patient in a much more comfortable condition than would otherwise have been the case; he did not suggest there was anything like lasting cure, but the destruction of the local lesion and the clearing up of sepsis rendered the patients' last days infinitely more endurable than if nothing of the kind had been done. Sometimes a secondary deposit also was amenable to diathermy treatment: He proceeded to discuss the technique of the operation in different conditions and the strength of current needed, and to give particulars of patients treated. The method was available for surgically operable cases also.—The contribution was fully discussed.

Dr. IRWIN MOORE read a paper on Eversion of the Sacculus Laryngis, and showed a number of illustrative slides. The matter has been before the Section on a previous occasion recently.

The Ventricle-Stripping Operation for Cord Paralysis.

Prof. F. HOBDAY read a paper setting forth his experience in 2000 operations on horses with paralysis of the vocal cord—manifested in "roaring"—by stripping the membrane from the ventricle of Morgagni, and suggesting that the operation was applicable to the human subject suffering from similar paralysis. He exhibited specimens to support his thesis.—Mr. TILLEY, Mr. M. E. VLASTO, Mr. S. B. WORTHINGTON, Mr. J. F. O'MALLEY, and the PRESIDENT discussed the paper and emphasised the differences between the human and equine larynges, and Prof. HOBDAY replied to the various criticisms.

Bronchoscopy in the Treatment of Asthma.

Mr. SYME submitted a contribution on the treatment of asthma by bronchoscopy and the use of a 10 per cent. solution of silver nitrate when the correction of nasal trouble or accessory sinus disease did not produce a lasting result on the asthma. He hesitated to use the word "cure" in severe cases, in which there were changes in the lung tissue, but in 12 such the benefit had been so decided as to enable the patients to resume their usual life, and he thought the results justified his reporting the method to the Section.—The paper was discussed.

In the afternoon Dr. REGINALD MORTON exhibited some recent developments in X ray treatment for laryngeal cases. Mr. G. T. MULLALLY showed the technique of blood transfusion, and Mr. T. B. LAYTON demonstrated some specimens from the recently acquired collection of the late Prof. Onodi, of Vienna.

Later in the afternoon the usual clinical meeting was held, when about a dozen cases were exhibited and discussed. In the evening members and visitors dined together.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

AT a meeting of this society held on June 3rd, at 11, Chandos-street, and presided over by Prof. W. J. R. SIMPSON, a paper was read by Lieut.-Col. H. KIRKPATRICK, I.M.S., entitled

Some Points Concerning Trachoma.

His subject called for little introduction, for the disease was well known as one of the chief causes of blindness in both Near and Far East, and for its association with bad hygiene and dirt. It was undoubtedly very infectious, and its spread was favoured by the harmful effects of dust and glare of the East, where among Mahomedans the use in common of the henna pot as a cosmetic was a fertile source of infection. Flies, though occasionally responsible for its conveyance, were not now regarded as an important factor. Following the Napoleonic wars England shared in the wave of infection which spread over Western Europe at the beginning of the last century, since when it had disappeared and was now rare in the British Isles, with the exception of parts of Ireland, where it still persisted, and when seen in England is chiefly confined to immigrants from the East. Colonel Kirkpatrick described trachoma as a specific and infectious inflammation of the conjunctiva, chronic in type and characterised by the formation in the membrane of follicles and papillæ, resulting in cicatrisation. He gave a detailed account of the structure of the conjunctival membrane and the anatomical relations of its three parts, the tarsal or palpebral, the fornical or transitional, and the bulbar. Reference was made to the normal development of papillæ in the tarsal portion and their inflammatory overgrowth in the early stage of trachoma. He described fully the pathology of the characteristic changes occurring in the conjunctiva—the general round-cell infiltration of the deeper layer and varying degree of vascular engorgement, together with the formation of pseudo-papillæ, tubular depressions of epithelium, and occlusion cysts. In particular the growth of the follicle was regarded as the striking feature of trachoma, composed of central large connective-tissue cells and peripheral zone of small lymphocytes in a stroma continuous with the connective tissue of the surrounding conjunctiva. The later stages of the follicles resulted in inflammatory cicatrisation and consequent deformity of the tarsus of the lid, leading to the *sinuous outline of the free margin. Pannus due to* cell invasion and vascularisation of the superficial layers of the cornea was of common occurrence. No organism had yet been discovered as the specific cause of trachoma, although many had been described.

Signs and Symptoms.

The lecturer proceeded to discuss in detail the symptoms and signs of the disease, which he divided into three stages: (1) An early or florid stage with formation of the characteristic follicles and *papillæ; (2) a middle or cicatricial stage;* (3) a late stage in which advanced cicatrisation of the conjunctiva with marked changes in the tarsus and cornea became evident. All stages tended to merge into one another. Ptosis, owing to inflammatory involvement of the insertion of the levator palpebræ, was commonly to be observed in the early stage. Vascularisation of the cornea, or pannus, generally developed during the middle stage, when all signs of the disease became more accentuated with the gradual network development of fibrous tissue in the conjunctival membrane, and the appearance of retention cysts. The formation of follicles in excess, giving rise to a pale yellow gelatinous mass on the tarsus, was known as Stellway's gelatinous trachoma. With continued cicatrisation and degeneration in the tarsal plate during the third stage, marked irregularity and deformity of the lids occurred and resulted in entropion, increasing pannus, and ulceration of the cornea, both much aggravated by trichiasis. *Finally, following on the* deposition of kerato-hyaline, the eye became dry, in the state known as xerophthalmia, the cornea more and more opaque, and total blindness eventually set in. The diagnosis of trachoma previous to the onset of the cicatricial stages was often a problem of great difficulty and called for differentiation particularly from follicular conjunctivitis, spring catarrh, and a chronic form of purulent conjunctivitis. During the early stages of trachoma the signs of most value were the presence of ptosis, the early occurrence *of pannus in the upper part of the cornea,* and, the situation of the trachoma follicles, best marked along the upper, or convex, margin of the superior tarsus, spreading upwards to the fold of the fornix and downwards on to the conjunctiva covering the tarsus. but much less evident in the lower fornix and conjunctiva of the lower lid. Colonel Kirkpatrick gave graphic details as to the differential diagnosis of the three conditions, above mentioned, for which trachoma was liable to be mistaken. In the treatment of the disease the first essential was the prevention of its spread by segregation of infected persons, the provision of separate basins and towels for each patient, the observance of proper precautions for cleansing the eyes, and the correct disposal of cloths soiled by conjunctival discharge.

Treatment.

In regard to treatment, the lecturer observed that it should aim at promoting the disappearance of the follicles without causing an excessive amount of fibrous tissue; the former was effected by Nature, in course of time, but by means of cicatrisation, which led to the serious complications and sequelæ. and it was to overcome these that every effort, whether medicinal or operative, should be directed. In the treatment of the first stage nitrate of silver in solutions varying from 5 to 60 grains to the ounce, but preferably 10 grains, or copper sulphate, applied in the form of a stick, were most in favour as medicinal applications to the affected areas of the conjunctiva; and these were best exposed by ballooning the fornix with a subconjunctival injection of sterile normal saline, *including 4 minims of 4 per cent.* solution of cocaine and 4 minims of adrenalin. The obstinate character of trachoma necessitated treatment, even in the first stage, over a period of some months, if the danger of relapse was to be avoided. More dical measures were occasionally advisable to fford more rapid relief, and for this purpose the operation of excision of the transitional portion of the conjunctiva, after ballooning with a local anæsthetic, *was advocated and described in detail.* In dealing with the second stage of the disease medicinal treatment was likely to be of little avail, and the adoption of operative measures was distinctly indicated, the most satisfactory being the combined excision of fornix and tarsus as described by Heisrath. A full and comprehensive account of this particular operation was given and illustrated by drawings thrown on the screen from the epidiascope. Following on the excision there was some reaction lasting about 36 hours, but it was possible to remove the stitches from the sutured conjunctiva and to commence painting with silver nitrate at the end of the first week. In the third stage of trachoma the membrane had undergone so much shrinkage that little of the fornix remained, but much benefit was to be derived from excision of the diseased tarsus, the possible reservoir of infection. The treatment of such complications as trichiasis and pannus, the latter occasionally by peritomy, and corneal ulceration by the use of scarlet R, 2 per cent. in olive oil, were called for in the third stage. The use of dionine for promoting absorption of corneal opacities, and instillation of 5 per cent. infusion of crushed jequirity seeds for the relief of pannus were mentioned as of considerable value. The trachomatous conjunctiva was especially liable to, and necessitated constant watch against, secondary infections—e.g., by the bacilli of Morax-Axenfeld and Koch-Weekes, calling for the use of sulphate of zinc drops and silver nitrate respectively. In gonococcal and particularly streptococcal infections, eye-baths of saturated magnesium sulphate solution were most useful remedies.

In conclusion, Colonel Kirkpatrick emphasised the following points: (1) that trachoma was not a single disease entity; (2) that the causes of the characteristic conjunctival changes might vary widely in different cases; (3) the importance of guarding against secondary infections; (4) the difficulty of diagnosis, as no causative organism had yet been established in trachoma.

Experiences with Chinese Labourers in France.

After opening remarks from the PRESIDENT, Dr. A. G. BAGSHAWE, the honorary secretary of the Society, read a letter from Dr. C. F. HARFORD, as the latter's contribution to the discussion. Dr. Harford quoted some of his experiences with Chinese labourers in France during 1917 and 1918 in order to show the great importance of trachoma from the epidemiological point of view, and the difficulties of diagnosis owing to the absence of any definite pathological test which could be applied to the disease. On a great ammunition dump at Dannes, where he was in medical charge of South African natives, two companies of Chinese were brought in who had been classified on their entry to France as "Trachoma Companies" and "Conjunctivitis Companies" respectively. Obviously, this was only a rough classification by which it was sought to segregate in the first class all who were potentially trachomatous, doubtful cases being collected in the second class. He had been asked to see some of the more acute cases taken from these companies on their first arrival at Dannes, and found it difficult to distinguish well-marked cases of trachoma. The more severe appeared to be similar to cases of muco-purulent conjunctivitis as seen in England with a red velvety conjunctiva covering sometimes irregular nodules. Later on at Havre he was called upon to inspect Chinese companies which had been classified as clean from the point of view of trachoma; even in these there was a distinct tendency to conjunctival irritation with a certain proportion of more serious cases. He attributed this to the lax eyelids of the Chinese and uncleanly habits. He contended that the object-lesson thus afforded during the war of the prevalence of contagious eye disease, and the difficulties of diagnosis, should lead to renewed inquiries both by the administrative and medical authorities in countries where these conditions were prevalent.

Lieut.-Colonel R. H. ELLIOT *stated his emphatic* belief that trachoma was responsible for more *blindness in India, Persia.* Afghanistan, and China than all other eye conditions put together; and he maintained that nothing like enough was being done by the Government to realise the necessity of grappling with the problem, especially in the earlier stages. For *trachoma, if* treated properly from the start, should never cause blindness. He heartily agreed with Colonel Kirkpatrick on two important points he had discussed: firstly, as to the great value of magnesium sulphate treatment of the conjunctiva; secondly, as to the ballooning of the conjunctiva, which had proved a most useful manœuvre both for diagnosis and treatment.

Colonel S. P. JAMES *inquired* if Colonel Kirkpatrick *from* his experience did not consider it important that trachoma should be made compulsorily notifiable in England.—Lieut.-Colonel KIRKPATRICK agreed as to the necessity that the condition ought to be notifiable as an infectious disease; and Lieut.-Colonel ELLIOT advocated a further step—namely, that all doubtful cases should be notified, whether definitely diagnosed as trachoma or not.

An Early Portuguese Contribution to Tropical Medicine, by Dr. CARLOS FRANÇA, Collares, Portugal, which had been translated by Professor Clifford Dobell, was submitted in the translator's absence by Dr. BAGSHAWE for publication in the Society's Transactions. The subject was of considerable interest in the history of medicine, dealing as it did with the first mention of some of the tropical diseases, ascribed to certain Portuguese physicians in the sixteenth and seventeenth centuries. The references included an account of *cholera*, by Garcia da Orta (1583); of yellow fever, by Ferreira da Rosa (1694); also descriptions by travellers, who were not medical men; of scurvy, by Joao de Barros (1552); of the cholera epidemic of 1543, by Gaspar Correia; and of *Dermatophilus penetrans*, in the production of what is now commonly known as "Chiggers," by Gaspar Affonso (1596). Mention was also made of a work of the sixteenth century containing a clear account of the part played by insects in the transmission of framboesia tropica (yaws), written by Gabriel de Souza, a Portuguese colonist of Brazil, in 1587. The account given by this shrewd observer of the sixteenth century had waited over three centuries for verification by the work of Castellani, who in 1907 demonstrated experimentally that the house fly (*Musca domestica*) could transmit the spirillum, *Treponema pertenue*, of yaws. It was rightly claimed, therefore, that the name of Gabriel de Souza was one which should henceforth figure in the history of Tropical Medicine.

TUBERCULOSIS SOCIETY.

A MEETING of this *Society was held on June* 6th at the Margaret Street Hospital for Consumption, London, when a *paper* was read by *Dr.* NATHAN RAW, M.P., President of the Society, on

What we do NOT *Know regarding Tuberculosis.*

He said that in spite of an enormous amount of research work by many of the greatest clinicians and scientists of the day there still remained great *uncertainty and* lack of knowledge on several fundamental and crucial points. Tubercle bacilli were divided *into three* types, *originally all of a* common species—human, bovine, and avian. The avian did not infect *man* and so could be disregarded. Just as the bacilli of tetanus and dysentery selected special organs, so the human and bovine tubercle bacilli attacked different parts of the human body. Speaking generally, Dr. Raw said that the human bacilli attacked the lungs and larynx, whereas the bovine attacked the alimentary system and the lymphatic glands. How and at what exact time a person became infected with pulmonary tuberculosis was *still a matter* of uncertainty, and how long the bacilli had the power to remain latent before acute symptoms developed was still unknown. The period of adolescence was undoubtedly a critical period *and one in* which the infection was stimulated to activity. Pulmonary tuberculosis was caused by the human bacillus in 90 per cent. of cases and was always primary. The remaining 10 per cent. were secondary to a primary infection by the bovine bacillus and were either an extension from the cervical glands downwards to the apex or an extension upwards from the abdomen to the bronchial glands. The problem of the bronchial glands was still unsolved, *and whether or not the bacilli live and flourish in the blood stream was still a matter of controversy. Diathesis* played an *important* part in predisposition to tuberculosis, and gouty people were much less susceptible than those of the diabetic diathesis. Tubercle bacilli varied greatly in virulence and to-day their virulence appeared to be much less than it was 50 years ago. The amount of individual resistance to attack and the degree of inherited tendency were still matters of uncertainty. Nomadic tribes were relatively free from *tuberculosis*, whereas *civilised nations* were *more susceptible*; and hence tuberculosis was really a *disease* of civilisation. Dr. Raw said that introduced into a primitive race it rapidly decimated the population, as this population had neither immunity nor resistance. How did civilised peoples become more or less immune to infection? Probably because the majority were infected with small doses which protect them against a more massive infection. Only a small proport*ion of married couples* were *infected, and this fact might* be ascribed to the non-infected *mate becoming* immunised by contact with the infected mate. There was a strong *antagonism* between the human and bovine types of the tubercle bacillus, and it had never been *found* possible to distinguish the two types in the same body. If the body were attacked by the human type and exposed afterwards to the bovine, the latter was incapable of causing infection. *Calmette had* shown also that it was possible to protect calves and other animals by using *attenuated* bacilli of the same *type. How was infection produced* and *how long might it remain latent?* The difficulties which arose when we *attempted to answer these* and *other questions* showed how little indeed we *do* know regarding tuberculosis and how much yet remained for research to accomplish.

Discussion.

Dr. H. B. GIBBINS remarked on the improvement *shown by many women suffering from tuberculosis* during pregnancy, for which improvement no adequate reason had been adduced, and on the *fact* that so few cases of the disease showed *physical signs* of excavitation.

Dr. A. SANDISON *commented* on the association of the colour of the hair with disease and noted that red hair was *more* commonly met with in the rheumatic diathesis, and black hair in the tuberculous. *Such association* might be a matter of considerable importance in prognosis, to which aspect of *the* problem he *thought too little attention* was paid in general; the psychology of the patient, his susceptibility to the influence of *suggestion in treatment*, had also been unduly *neglected*.

Dr. F. HERNAMAN-JOHNSON *stated that, so far as* the X *rays* showed, pulmonary tuberculosis always appeared to begin in the hilus glands and *to spread* therefrom, bandwise or fanwise, towards the apex, which might or might not show signs *of being affected*. A pure apical tuberculosis was never found without definite signs at the root, though the connexion *between* them might not, however, be very obvious.

Dr. HENRY A. ELLIS called *attention* to the difference in prognosis between man and woman. The proportion of deaths in man grew greater as age increased, whereas the *death-rate* in woman was *highest* between the ages of 15 to 25. In regard to the question of immunity he *pointed out that, if* cases were injected with tuberculin in the pre-tuberculous stage, tuberculosis would *not develop in them*.

Dr. CAMPBELL MCCLURE considered that one of the *most* hopeful signs of the times was the *tendency* to leave theory alone and to concentrate on the tabulation of large series of cases. Two most important questions were (1) diathesis; and (2) the low death-rate from the disease compared with the high incidence-rate.

Dr. JOHN SORLEY thought that some of those who held views on the production of immunity by small infecting doses did not always have the courage of their convictions and put these views into practice. It might be possible to produce immunity by administering small doses of living bovine bacilli to children in milk, but one could not guarantee that disaster might not result, and parents were not likely to offer their children for experimentation in view of this uncertainty.

Dr. ELLIS showed the upper lobe of the lung of a lion which had died of pulmonary tuberculosis. The whole lobe was one large cavity. The specimen was obtained from the Zoological Gardens through the kindness of Dr. C. F. Sonntag.

Reviews and Notices of Books.

DIATHERMY.

Its Production and Uses in Medicine and Surgery. By ELKIN P. CUMBERBATCH, M.A., B.M. Oxon., M.R.C.P. London: Wm. Heinemann (Medical Books), Ltd. 1921. 44 illustrations. Pp. 193. 21s.

THE author takes the trouble at the outset to explain the term diathermy, which means the "through heating" which occurs on the passage through the body of an electric current of special kind. A brief history of the way in which these currents came into use is followed by the technical features which distinguish both their production and their application to the body in conditions of disease.

The subject is a comparatively new one; the first diathermy machine for medical use was introduced into this country by the late Dr. Lewis Jones in 1909. Dr. Cumberbatch's work on diathermy is well known to those conversant with the subject; the author's particular studies on the rise in temperature of various parts of the body traversed by diathermic currents form the subject-matter of Chapter VI.; they will repay careful perusal, for they are well-planned experiments. Further experimental work by Dr. Cumberbatch upon physiological lines—for example, the effect of diathermy upon blood pressure, pulse-rate, and respiratory exchange—paves the way for an appreciation of the medical possibilities of this special form of electric current. One of the most striking features of electrical currents, which alternate with great frequency, is their inability to stimulate the excitable tissues. Until quite recently no explanation of this has been offered, but researches upon this phenomenon have now shown that the power of an electric current to stimulate the excitable tissues depends both upon the strength of the current and upon its duration; if the latter falls below a certain critical value the current loses altogether the power of excitation. The diathermic currents flow for less than this critical period of time before they reverse and therefore have no stimulating action; the sensation of warmth which is felt is due to the actual generation of heat within the tissues by these currents. The body can tolerate sufficiently large currents of this kind to allow of a very considerable rise of temperature; herein lies the possibility of surgical applications of these currents, discussion of which forms the concluding chapter of the volume.

The book is an excellent one. The subject is dealt with in a thoroughly scientific manner, the descriptions of the various types of diathermy machines at present in use are brief but lucid; the author has a scrupulous regard for exactness in every detail of his subject. On p. 16 an inversion of sentences occurs which the author will doubtless correct in future editions. The book is illustrated with line drawings and plates which enhance but do not over-balance the letterpress.

OBSTETRICAL AND GYNÆCOLOGICAL MONOGRAPHS.

Pelvic Inflammation in Women. By JOHN OSBORN POLAK, M.Sc., M.D., F.A.C.S., Professor of Obstetrics and Gynæcology, Long Island College Hospital, &c. London and New York: D. Appleton and Co. 1921. With 2 coloured plates and 88 illustrations. Pp. 229. £1 1s.

THIS monograph deals with the large group of diseases peculiar to women which result from septic, gonorrhœal, and tuberculous infections, and an attempt has been made to give the accepted pathology, a definite clinical picture, and the treatment. Dr. Polak uses the term pelvic inflammation in the wide sense, since he deals with this condition as it affects all parts of the genital tract. The book contains a great deal that is interesting. The author has a very profound belief in the prevalence of gonorrhœa in the female, and considers it a potent cause of pelvic inflammation and of one child sterility. He quotes the well-known figures of Nöggerath, the accuracy of which we are inclined to doubt. However, as is well known, the proof is difficult to obtain owing to the rapid disappearance of the gonococcus in these cases. Dr. Polak maintains that pyogenic cocci not infrequently persist in the prostate of men who have had gonorrhœa, and that in some cases they are the cause of infection in their wives. Considerable stress is laid upon the frequency of gonorrhœal infection of the mucosa of the cervix, and its treatment by a cone-shaped excision of the affected area is recommended in bad cases.

The chapter dealing with gonorrhœal infection is a very good one, and in the section on treatment great stress is laid on the importance of preventing the upward spread of the disease. In discussing the treatment of cases of puerperal infection the author strongly maintains that local interference is practically always contra-indicated and entirely condemns manual manipulations within the uterus or the use of the curette. In dealing with cases of puerperal pyæmia and general puerperal infection, treatment by sunlight, food, fresh air, repeated small blood transfusions, and general supportive stimulation is advised. Dr. Polak believes that by the repeated transfusions of small quantities—300–500 c.cm.—of citrated blood it is possible to lessen the secondary anæmia, to increase the number of active leucocytes, and to raise the blood pressure. Reliance is also placed on postural drainage by Fowler's position, proctoclysis, posterior colpotomy, and packing the pelvic cavity with gauze after the method introduced by Pryor. In the radical treatment of cases of salpingitis it is urged that no operative procedure should be undertaken until all acute symptoms have subsided. The case is tested by a blood count and a thorough bimanual pelvic examination. If after this the temperature and the leucocytes are not raised the operation may be performed with safety. Four very interesting cases are quoted in this chapter, in which the streptococcus lay latent in a parametrial exudate for periods varying from five to 15 years, and then gave birth to a general infection. In removing infected tubes Dr. Polak recommends the procedure by which a wedge-shaped portion of the fundus of the uterus, including the pars interstitialis, is resected. Resection of the ovary on general principles, in his opinion, should be discouraged.

Dr. Polak's book is interesting and valuable, and contains a great deal of information based on sound principles and on a wide experience.

Cæsarean Section. By FRANKLIN S. NEWELL, A.B., M.D., Professor of Clinical Obstetrics, Harvard University; Obstetrician, Massachusetts General Hospital. London and New York: D. Appleton and Co. 1921. With 53 illustrations. Pp. 210. £1 1s.

THE operation of Cæsarean section is occupying so large a place in the treatment of many complications of labour at the present time that a methodical review of the operation and its results, such as this monograph contains, is of great interest and value. Professor Newell is an obstetrician of considerable experience, and it is refreshing to see that he, at any rate, is not so enamoured of the frequent performance of Cæsarean sections as a means of overcoming many of the accidents of labour as are a number of the younger obstetricians at the present day. As he points out, the operation is undoubtedly abused, and "its true value can only be appreciated when it is applied to properly selected patients by competent operators." On the whole he declares himself in favour of the classical operation, and does not think that the various modifications introduced have any real advantages. At the same time he admits that the good results obtained by Kustner in his extraperitoneal method, namely 112 cases with only two deaths, are very striking, and show the method to have good features.

Professor Newell's teaching with regard to the treatment of contracted pelves by abdominal section is that generally recognised by the majority of teachers. In dealing with ovarian tumours he favours Cæsarean section followed by ovariotomy. He agrees in general with the dictum "Once a Cæsarean always a Cæsarean." In cases of eclampsia he believes the operation has a limited application, but on the whole he agrees with the conservative school, who prefer to treat the eclampsia rather than to terminate the pregnancy. In placenta prævia he is in favour of version or the use of a hydrostatic bag, and does not see any likelihood of the maternal or the fœtal mortality being lowered by the more frequent performance of Cæsarean section. In the worst cases of accidental hæmorrhage he recommends delivery by the abdominal route. In performing the operation he follows the usual technique, and sees no special advantages either in the subumbilical incision or in opening the uterus through the lower uterine segment. As he points out, the performance of an ordinary classical Cæsarean section calls for much less skill or knowledge than the delivery of a patient in a difficult case of labour by the vagina, and this is one of the main reasons why the operation at the present time is so often performed on occasions when it is not certainly the best or the safest method of delivering the patient.

The book is a very sound piece of work, and Dr. Newell's views are in harmony with those of the majority of experienced teachers of the subject.

COUNSELS AND IDEALS FROM THE WRITINGS OF WILLIAM OSLER.

Second edition. Selected and edited by C. N. B. CAMAC. London: Humphrey Milford, Oxford University Press. 1921. Pp. 355. 8s. 6d.

COLLECTIONS of extracts from any author are, as a rule, unsatisfactory, except in the case of poets, where whole short poems can be given. This collection is to our minds no exception to the rule, despite Dr. Camac's statement on p. xv. of his preface to this second edition, though we agree that a few of the extracts lose nothing by being divorced from their context. But for an anthology Dr. Camac's selection is well made, and those who have neither the leisure nor the opportunity to read Osler's works in their entirety will find fragments of gold dust which may well set them seeking in the matrix where lies the original metal.

Osler was widely read and steeped in seventeenth-century literature. Sir Thomas Browne one may almost say he knew by heart, while the language of the Authorised Version and of the Prayer Book appears again and again in his writings; and though he was eminently practical, and though there perhaps never lived a clearer teacher, yet in his writings we feel the vague detachment from the troubles of this world which we feel in reading Browne, or Vaughan, or Feltham, who wrote that wise book of "Resolves" when only 18. In these troublous times it is well for us to read Osler and to remember one of his rules of life—"to do the day's work well, and not to bother about to-morrow." To no man more than to Osler does the dictum of St. Bernard apply, "Tu qui in Congregatione es, bene vive, ordinabiliter, sociabiliter, et humiliter: Ordinabiliter tibi, sociabiliter proximo, humiliter Deo." We must refer to an error which occurs on p. 24, where we find "Nowhere in literature do we have such a charming picture . . . as that given in Plato's *Dialogues of Eryximachus*, himself the son of a physician, Acumenus." Of course this should read, "as that given in Plato's *Dialogues*, of Eryximachus." In a third edition this should be corrected.

INTERNAL SECRETIONS.

Die Innere Sekretion. By Dr. ARTHUR WEIL, Privat Dozent der Physiologie an der Universität Halle. Berlin: Julius Springer. 1921. Pp. 140. M.28.

THE author has compressed into a volume of 140 pages a mass of scientific fact and theory. He gives a concise summary of our present knowledge of the internal secretions in regard to their functions, their influence on the growth and development of the body generally, and discusses the minute histology of the glands. He is no slave to the idea that the internal secretions alone reveal to us the secrets of life; they do not, he says, rule over all, but share with the brain and nervous system the regulation of the course of life. The composition of the blood and the influence thereon of the secretions of the thyroid, thymus, and suprarenal are discussed fully by Dr. Weil, while special reference is made to the ferments of the plasma and the effect of the injections of gland extracts on coagulation-time. He explains that both factors in the circulation of the blood, the activity of the heart and the resistance of the peripheral circulation, are under the influence of the internal secretions, the thyroid and suprarenals increasing the excitability of the nerve endings, whilst the pituitary acts directly on the heart muscles.

In discussing metabolism, he shows how in thyroidism the negative nitrogen balance can be lessened by full doses of fat and carbohydrate; as to heat production, he maintains that the thyroid and pituitary increase heat by stimulating cell oxidation, whilst the adrenals act physically by their action in contracting the peripheral vessels. Many authorities would disagree with Dr. Weil here, and would claim that the thyroid acts partly by increasing the electrical conductivity of the tissues, and that the suprarenal is directly concerned with cell oxidation. Dr. Weil considers that the kidney has its own internal secretion, on the grounds that experimental injections of kidney extract reduce the symptoms of uræmia after the removal of the kidneys. The relation of the pituitary to the kidney, and the action of cholin on the intestinal contractions, are also discussed by Dr. Weil, who points out that there is more of this latter base in the adrenals and spleen than in the intestinal mucous membrane. In dealing with the theory of the vitamins, he suggests the possibility of their being antecedents of the internal secretions, and shows the similarity in the chemical formulæ of tyrosin, tyramine, hordenin, and adrenalin, and further directs attention to the resemblance between pellagra and Addison's disease, and to the degenerative changes in the ductless gland, especially the thymus, in beri-beri. The influence of the internal secretions, more especially those of the thyroid, parathyroid, thymus, sexual organs, and pituitary, on the rate of growth, relative development of the different parts of the body, and the variations in the two sexes form the subject-matter of another section of the book. Dr. Weil describes the development of the sexual organs and shows how the testicular and ovarian secretions influence the development of the sexual characteristics of the male and female.

Experimental change of sex is illustrated by a photograph of some guinea-pigs, in whom transplantation of the glands of the opposite sex was effected. Dr. Weil recognises three ovarian secretions, one related to the development of form, another concerned with the function of menstruation, and the third, which he associates with the corpus luteum, connected with the development of the placenta. In hibernating animals he has found atrophy of the sex organs in the autumn and asserts that the thyroid and pituitary are similarly atrophied. Recent work in America by Rasmussen on the woodchuck does not support this as regards the hypophysis. Mental conditions Dr. Weil regards as directly under the influence of the internal secretions. The nervous system regulates the ductless glands as well as other organs of the body; on the other hand, these glands in their turn influence the nervous system. The chemistry of the internal secretions, as far as they have been investigated, is discussed, and formulæ are given of adrenalin, cholin, thyroxin, and spermin; the isolation by Hermann of a hormone from the ovary, and by Fühner of a crystalline substance of chemical structure still undetermined from the hypophysis, is mentioned.

The illustrations in the book are excellent and the various tables instructive. Altogether the volume can be recommended to those who desire a concise review of the present knowledge of the internal secretions. The clinical aspect is not dealt with.

The Community Health Problem.

By Athel Campbell Burnham, M.D., Health Service, Atlantic Division, American Red Cross, &c. London and New York: The Macmillan Company. 1920. Pp. 160. 8s. 6d.

The author's preface tells us this book is intended to give welfare workers, public health nurses, and practising physicians an outline of the measures which are being suggested for the solution of the health problem as it exists in the United States. The problem as it exists in Great Britain does not differ in essentials, and for that reason we feel sure that Dr. Burnham's book will be read with interest by a wide circle of readers in this country. In our issue of April 9th we commented at length on the recently issued Hospital and Health Survey in Cleveland, Ohio, and it is justifiable to deduce that experiments have been carried further in this country than in the United States as a whole. No general system of school clinics, tuberculosis dispensaries, maternity and child welfare centres, free venereal disease clinics, and medical treatment on the insurance principle has as yet been established in the States. In this respect the Americans will be able to benefit by our experience and our failures. We well recognise, however, that we are only in the experimental stage, and that our own medical service is in the melting-pot. We have a long way to go before we secure for each family a family doctor with a public health point of view, who will be called upon when required (irrespective of the fear of a bill which may cripple the resources of the family perhaps for years), and who will be linked up with consulting physicians and surgeons, dentists, hospitals, convalescent homes, midwives, district nurses, and mothers' helps in such a way that his patients may have the benefit of these services in time of need. This is, in fact, something like the problem which Dr. Burnham puts before his readers.

In Chapter I. the author endeavours to give some idea of the extent of sickness disability. He estimates that about 6 per cent. of an average community are always in need of medical treatment, and that sickness leads on an average to a loss of nine days wages per head per year. He lays stress upon the small amount of the public expenditure to prevent sickness, and instances the work of the Rockefeller Foundation as an example which should be followed by public bodies. The fact that the private physician has neither the experience nor the time to practise preventive medicine is emphasised. Chapter V. is devoted to the important part that must be played by public health nurses in any satisfactory "programme for the betterment of community health." In the next chapter the question of the rehabilitation of the disabled worker is discussed, and the methods are noted of the Ford Company, which can boast that a man is never discharged from their employ because of physical disability. "If he is unfit for his former occupation, he is trained for another." In a later chapter we learn from Dr. Burnham that the Federal Board was overwhelmed with the problem of training the men disabled through the war. This is somewhat surprising when we consider the immense financial resources available and the comparative size of the problem to be faced in the United States and in the other belligerent countries.

Interesting experiments in industrial medicine, in the establishment of health centres and in social unit organisations are recorded in other chapters, and the book ends with some account of endowed health demonstrations such as the Rockefeller and Russell Sage Foundations.

War Diaries.

The Diary of an Australian Soldier (Captain K. J. Barrett). Melbourne and Sydney: The Lothian Book Publishing Co. 1921. Pp. 222. 7s. 6d.

Books about the war are many, but it is right and natural that this should be so. The one before us is of particular interest as a simple record, kept for the information of his family, by a young Australian officer, who, like so many others, developed both in character and grasp of things under the strain of military necessity.

Keith Barrett's father, Lieut.-Col. Sir J. W. Barrett, A.A.M.C., who writes a preface to the diary, points out that his son was not distinguished as a boy by any scholastic ability, but that the training in the officers' instruction school developed him in a remarkable manner. Moreover, he has left behind him various essays on discipline, on making men comfortable, and on other branches of knowledge essential for an officer, which, if they are anything like the diary, would be well worth publishing. Barrett received his training in Egypt in 1915, when he was given a commission in the Imperial Army, having on the outbreak of war volunteered as private in the 2nd Field Ambulance (Queensland). He served first in the Dardanelles and then in France, was twice mentioned in despatches during his life, and again after his death, which occurred on April 16th, 1917, from wounds received at Guemappe three days previously. For his work at the capture of "The Harp" on April 9th he was recommended for the D.S.O. The diary is a plain unvarnished record of the hard work, the failures, the successes, and the daily routine of warfare, but is full of little touches which show what manner of man was the young officer of the improvised armies, how earnestly he strove to do his duty, and how his whole thought was for his men.

The Diary of a Yeomanry M.O. By Captain O. Teichman, D.S.O., M.C., Croix de Guerre, Croce di Guerra, R.A.M.C. (T.F.). London: T. Fisher Unwin. Pp. 283. 12s. 6d.

This book is remarkable for the self-effacement of the writer. We see by the title-page that Captain Teichman gained most honourable distinctions, yet the reader would hardly gather from his pages that he was anything but an intelligent observer who had accompanied the forces on various fronts; who had a certain amount of military knowledge and was rather interested in medical matters. He served in Egypt, the Gallipoli Peninsula, Palestine, and on the Piave, and on at least two occasions was wounded. The greater part of his service was in the Palestine campaign, and he gives a graphic account of the sufferings endured by both men and animals mainly on account of lack of water, but his own share of the work is mentioned only impersonally.

Here and there he tells good stories. On p. 215 we hear of a private in an Egyptian Labour Corps who was anxious to return to Egypt. He accordingly wrote the following moving appeal to his C.O.: "Sir, my absence is impossible, some man has uprooted my wife, my God I am annoyed; yours faithfully." Captain Teichman does not say whether the writer obtained his leave, but we think he did. Another incident occurred during his service in Italy when he was acting S.M.O. of Faenza, where there were two hospitals, British and Indian, fed by train from various Eastern fronts. On p. 255 he relates how "on one occasion a train containing Indians suffering from mumps was held up for half a day near the station, being shunted on to a siding; when it had continued its journey the local sanitary authorities disinfected the permanent way, but later it transpired that the engine which had drawn the train had been waiting on another siding, and accordingly the rails on which it had stood were also solemnly disinfected." It is pleasing to think that so meticulous a regard for prevention has survived in Italy for some seven hundred years, for Ammianus Marcellinus, writing of the year 353 A.D., tells us in his account of Rome, Bk. XIV., cap. 6, that the fashionable Roman society of the day was so afraid of infection that not only did they decline to see a sick friend, but even when they sent a slave to inquire after him the slave was not permitted to re-enter the house with the answer until he had had a bath.

We take leave of Captain Teichman's book, with a recommendation that it should be read, and add only that we wish he had told us a little more about himself.

CLINICAL EXAMINATION OF DISEASES OF THE LUNGS.

By E. M. BROCKBANK, M.D., F.R.C.P., and ALBERT RAMSBOTTOM, M.D., F.R.C.P. London: H. K. Lewis and Co. 1921. Pp. 88. 4*s.* 6*d.*

THE title of this useful little book suggests that the authors examine diseases rather than the organs in which they occur, and this seems a topsy-turvy notion. In the covers of much standard information, the authors sandwich in many useful hints which are far too rare in text-books. Thus, in the case of a short, persistent, dry cough, they give the sensible but rather unusual advice that the physician should search for its cause in the external auditory meatus. Again, with regard to paracentesis abdominis in a case complicated by bronchitis they advise caution, pointing out that if the fluid be removed, the stretched abdominal muscles may no longer be able to help the diaphragm and thoracic muscles in their expulsive efforts in coughing. "The result is that the patient cannot get rid of the bronchial secretion, and may easily be drowned in his own sputum." The authors' English is deplorably inelegant, but this is a matter of secondary importance in a handbook of this description.

THE RHYTHMIC DANCE-BOOK.

By MARGARET EINERT. London: Longmans, Green and Co. 1921. Pp. 96. 4*s.* 6*d.*

Miss Margaret Einert, in her small and readable book, tells us that a sound mind in a sound body is not enough, there must also be a sound emotional nature. In order that this may be cultivated, she advocates that children should dance to express their joy in life. They must dance with body and head and arms as well as with feet. They must not move to the music; they must be moved by it. "Imagine," she says, "a fresh green lawn and a fiddler roaming about, playing as he walks from sheer happiness and love of his art. Imagine then a flock of loose-clad children dotted all about among the flowers and the sunshine." Rhythmic dancing, according to the enthusiasts, makes for joyous health, for complete coördination and control, for imagination, for self-realisation.

One delightful chapter in Miss Einert's book deals with stories in movement. For instance, children are asked to dance as though they were on the sea-shore. At once they picture sands, surf, waves, storms, thunder, and mermaids, and mark on the grass a section for sand, one for surf, and one for deep sea. They listen quietly to the music played once through and then they dance. The storm and the waves have their appropriate musical passages, and six children dancing together are taught to represent the curling wave, the incoming tide, the break of the surf on the sand. The teacher unfolds the story a little. Calm sets in after the storm, the sun comes out, and to a gentle melody the children spring forward to the shallow water and at once become mermaids combing out their long hair in the sunshine. Another dance-story represents the spirit of Christmas—another "*The Wind and the Rose.*" Further chapters deal with verse-dancing, with plastic posing, and with suitable clothing to allow freedom of movement.

A charming book with a strong eugenic side.

Reports and Analytical Records.

ETHANESAL.

(SAVORY AND MOORE, LTD., 143, NEW BOND-STREET, LONDON, W.)

THIS anæsthetic apparently has the physical properties of ether. It is anhydrous, free from sulphur compounds, and has a neutral reaction. It contains a very small amount of a substance oxidised to acetaldehyde by chromic acid, which presumably is ethylic alcohol. Ethanesal commences to boil at 33·9°C. When fractionated:—

41	per cent. distilled over between	33·9° and 35·0°C.
13	" " " "	35·0° " 36·1°
16	" " " "	36·1° " 37·8°
28	" " " "	37·8° " 40·2°
2	" " " "	above 40·2°

When ordinary B.P. ether is fractionally distilled some 97·5 to 98·5 per cent. passes over at 34° to 36°C., hence it is obvious that ethanesal is a mixture of substances having a boiling-point not far removed from that of ether. According to the statements of Dr. R. L. Mackenzie Wallis and Dr. C. L. Hewer in THE LANCET of June 4th (p. 1173) it appears that the anæsthetic properties of ether are due to the presence of certain ketones. Ethanesal is a mixture of pure ether and these ketones, and the introduction of this anæsthetic may be regarded as a distinct advance in anæsthetic practice.

TUBERCLE VACCINE R.

(ALLEN AND HANBURYS, LTD., LONDON.)

We have received two sample boxes of this preparation, introduced on personal trial by Dr. Nathan Raw, together with an explanatory pamphlet. According to the latter, this vaccine, which is designed for use both as a curative and prophylactic agent, is prepared from cultures of *B. tuberculosis*, subcultured without a break for 14 years. The vaccine is to be administered on the principle advocated by Dr. Raw, that the two types of disease, human and bovine tuberculosis, are antagonistic to one another, and that a mild infection of the one protects against the other. It is suggested that doses should begin at 0·001 mg. and be continued for at least 12 injections in increasing doses at intervals of seven days up to 0·025 mg. The pamphlet does not state whether the bacilli have been killed by heat, and if so, at what temperature, or by the addition of antiseptics. The price of the vaccine is 5*s.* per dose.

Each box contained three ampoules of 0·001, 0.002, and 0·003 mg. vaccine respectively, marked human strain. The contents of a 0·003 mg. ampoule when centrifuged showed small numbers of intact acid-fast bacilli, morphologically resembling tubercle bacilli with no sign of disintegrated organisms. Cultures on glycerinated Dorset's egg medium remained sterile. No secondary organisms were found either in films or on ordinary culture media (broth and agar). Two guinea-pigs were inoculated subcutaneously with the vaccine; one was given 0·003 mg. and the other 0·006 mg. No toxic symptoms were observed following inoculation and when killed three weeks later no signs of tuberculosis were observed macroscopically or microscopically.

QUINOSAL.

(S. H. M. Co., Ltd., Sutton, Heston, Middlesex.)

This preparation is made from quinine ethyl carbonate, known as euquinine or tasteless quinine and salicylic acid. It is in the form of small crystals melting at 197°C., and when analysed was found to consist of salicylic acid 25·2 per cent.; and quinine ethyl carbonate 74·4 per cent., water nil, ash nil. Quinosal is therefore a definite chemical compound with the composition corresponding to the salicylate of quinine ethyl carbonate. Quinine salicylate has been recommended for diarrhœa and neuralgia, rheumatism and sciatica. Quinosal is intended as a tasteless substitute for this drug. It is satisfactory to see that English manufacturers are placing high-class synthetic drugs of this kind on the home market. We are informed that the S. H. M. Co., are the sole makers of quinine ethyl carbonate in this country.

HÉMOSTYL.

(Wilcox, Jozeau and Co., 49, Haymarket, London, S.W.)

Three ten cubic centimetre flasks of this serum were received for examination. It is obtained from the horse by bleeding the animal during the regeneration phase which follows a hæmorrhage. This is done on the principle that the hæmopoietic properties of the serum are increased during this period. On examination the serum was found to yield no growth on aerobic or anaerobic cultures. Injected subcutaneously into a guinea-pig, the serum gave rise to no toxic symptoms and a second dose repeated three weeks later caused no anaphylaxis. The serum, therefore, is non-toxic and non-anaphylactic and is free from contaminating organisms.

LYSOL WARD SOAP.

(Lysol, Ltd., 9 and 10, St. Mary-at-Hill, London, E.C.)

On analysis we find this soap has the following percentage composition: Fatty anhydrides, 54·4; Na_2O, combined as soap, 6·2; Na_2O, combined as Na_2CO_3, 0·3; free alkali as NaOH, trace; and water, 37·9 per cent. Resin acids are present, and the claim that the soap contains 3 per cent. of cresols is substantially correct, a content which confers definite antiseptic properties. It is stated that this soap is manufactured for hospital and household use and that it is particularly suitable for the washing of flannels. The retail price is about *8d.* per lb., but in comparing this with other domestic soaps the high percentage of water (37·9) should not be lost sight of.

TURNWRIGHT'S TOFFEE DE-LIGHT.

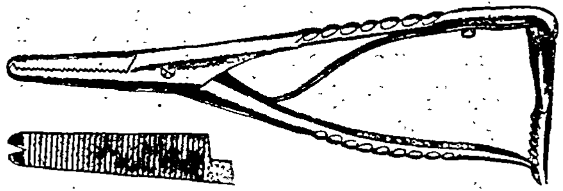
(Turner and Wainwright, Ltd., Brookfoot Mills, Brighouse, Yorkshire.)

On analysis this toffee was found to consist of sugar 65·9, water 7·3, fat 18·7, proteins 2·5, sodium chloride 0·6 per cent. These figures correspond to a mixture of sugars 65·9, dried milk 10, fat (other than that in the dried milk) 16·2, and moisture 7·3 per cent. The salt is probably added with a view to improving the flavour. The texture of this toffee, in common with many other popular modern brands, is soft and caramel-like in character and quite unlike the old-fashioned brittle preparations. The mixture is a well-proportioned one and furnishes a palatable and nutritious sweetmeat.

New Inventions.

A NEW APPENDIX CLAMP.

In appendicectomy the usual routine is to divide the appendix between two pairs of forceps. By this procedure the contents of the appendix are forced into the part between the two forceps, and, to prevent the spread of infection, the surgeon is compelled to resort to the inevitable "drop of pure carbolic." To avoid this troublesome procedure I have devised the instrument here illustrated, which is as easy to apply as a pair of forceps. The clamping part of the instrument is wide enough (9 mm.) to allow the base of the appendix to be ligatured and divided at the crushed part, the peritoneal surfaces of which are brought into apposition so that the appendix contents are forced away from the region of ligature and division. The crushing surfaces of the clamp bear fine transverse serrations which fix the appendix transversely. In my opinion clamps with smooth unserrated surfaces which act equally in all directions, unless they are narrow like Mr. Donald Armour's ingenious instrument, tend to produce a longitudinal rupture of the appendix. The ratchet catch and spring are similar to those used in various forms of needle holders, and are locked and unlocked with the greatest ease.

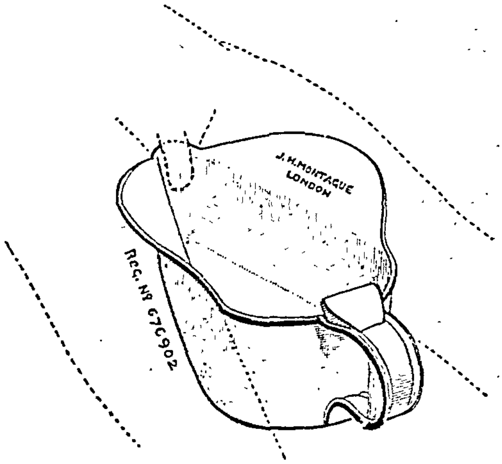


The clamp has been made in accordance with my suggestions by Messrs. Arnold and Sons.

Welbeck-street, W. W. K. Irwin, F.R.C.S.Edin.

A UROLOGICAL BASIN.

The urological basin illustrated is of great assistance in the treatment of urethritis and cystitis when irrigation is required. It is specially designed to fit firmly between the thighs without causing undue pressure on the posterior urethra which sometimes occurs when other appliances of the same nature are used. The flanges cover the inner surface of the thighs, and it is so constructed that no splashing or leaking over the sides can occur, which makes it particularly useful when treatment is carried out with the patient in bed. It will hold more than three pints of fluid and therefore does not require to be emptied during treatment. Lastly it is made of enamel iron and therefore can be sterilised by boiling. Mr. J. H. Montague, 69, New Bond-street, W.1, is the maker.



Welbeck-street, W. Walter J. Ronan, M.B. Dub.

THE LANCET.

LONDON: SATURDAY, JUNE 18, 1921.

The Report of Lord Cave's Committee.

THE anxiously expected report of Lord Cave's Committee upon hospital finance has made its appearance. This Committee, it will be remembered, was appointed by Dr. Addison during the debates at the end of last year before a Standing Committee of the House of Commons upon the Ministry of Health (Miscellaneous Provisions) Bill. This measure, which was afterwards rejected by the House of Lords, contained a clause around which important medical discussion centred, inasmuch as it sought to give powers to county councils to supply and maintain hospitals, to contribute to voluntary hospitals, and to undertake the maintenance of Poor-law hospitals and institutions. It was felt in many quarters that such legislation might prejudice the voluntary system of hospital support at a critical time, and Dr. Addison accordingly appointed a Committee "to enquire into and report upon the financial position of the voluntary hospitals throughout the country." This Committee, under the chairmanship of Lord Cave, and consisting of five members only, none of them being medical men or connected with hospital arrangements in any way, issued an interim report at the end of March. The document, which was signed by all the members of the committee, confirmed the view that it is in the public interest to maintain the voluntary system of hospital management, and gave reasons for believing that from the Approved Societies, under the National Health Insurance Acts, a substantial part of the disposable surplus shown by the quinquennial valuation of the assets of the societies should be applied towards the cost of the maintenance of members of the societies while they are in hospital. There is no doubt that the voluntary hospitals are of enormous service to the Approved Societies, and the interim report of Lord Cave's Committee had an *excellent reception.*

Late last week the report of Lord Cave's Committee was published, and we were able to give the recommendations, which we repeat this week, together with an abstract of the report. It will be seen that as a main principle the Committee regard the coöperation of the National Health Insurance Commission as essential to their scheme for preserving the voluntary system, which they state definitely to be temporarily in jeopardy. They are convinced that the system is worth saving, and the reasons which they give are practically the same as those that have been advanced over and over again in these columns, whenever the system has been challenged. Freedom in medicine is secured by the voluntary principle; progress and medical research are fostered by it; and in no other way can the education of the medical profession be carried on so satisfactorily as at medical schools which are in close association with a large voluntary hospital. A system with testimonials of this character to its credit is not likely to die without a struggle, and though it may be temporarily open to criticism—the balance sheets at many of the great institutions supply justification for this—there is no reason to doubt, and we have never doubted, that the existing financial conditions are temporary. They are due partly to the circumstances produced by the war, partly to the old-fashioned methods of collecting funds, which have become a stereotyped routine with many of the charities, and partly to faulty methods of spending money. Lord Cave's Committee draws attention to procedures which can be undertaken by managers of voluntary hospitals to improve the financial position of their hospitals, and many of their suggestions have been made in these columns and elsewhere upon a good many occasions.

The first clause recommends the formation of a Hospitals Commission, with the institution of Voluntary Hospitals Committees for the country, and we are certain that the central organisation of the charities thus implied will lead both to efficiency and economy. In this way the best methods of administration can be ascertained by comparison and the lessons learnt made the common property of the hospitals And a further admirable suggestion in respect of such a Hospitals Commission closes the Report. The last clause states that the Hospitals Commission should be authorised during a period of two years to recommend grants for the extension and improvement of hospitals subject to like contributions being made from private sources. A previous recommendation would sanction an immediate grant to the Commission of £1,000,000, so that in the intent to make a joint scheme of benevolence between the public and the State it is left to the State to make the first move.

Treatment of Whooping-Cough.

IN few acute diseases have a larger number of supposed remedies been advocated than in the case of whooping-cough—a sure sign of their doubtful efficacy. The sceptic or nihilist in therapeutics will read with a more or less indulgent smile the description given by Dr. J. D. Rolleston in the June number of *Medical Science* of the various forms of treatment which have been recommended for this disease within the last two years. The principal novelty first introduced by Audrain of Caen, and subsequently employed by Weill and Dufourt, Gleyvod of Lyons, Cheinisse of Paris, and other French physicians, is the intramuscular injection of ether, which is given in the upper part of the buttock. The ether is supposed to act by combating the spasmodic element of the disease, and is not regarded as having a specific action on the infective agent of pertussis. The dose employed is 1 c.cm. up to the age of 7 or 8 months, and in older children 2 c.cm. repeated daily or on alternate days. Weill and Dufourt, who consider this method to be far superior to any other in the treatment of pertussis, regard it as specially indicated in cases with numerous and severe paroxysms, and claim that after a few injections the children have only abortive attacks unaccompanied by vomiting. Gleyvod, who reports eight cases in children aged from 2¼ months to 8 years, treated by intramuscular injections of ether in Weill's clinic, states that the first injections always have a more striking effect than subsequent ones, the system apparently becoming habituated to the drug. If a decided improvement occurs after the second or third injection no more need be given. As a general rule, however, six injections will be required to produce a permanent effect, and a greater number is unnecessary. Although it is dangerous to give ether in the large doses employed in anaesthesia to patients suffering from chronic disease of the lungs or bronchi, such as asthma, emphysema, or tuberculosis, there is no contra-indication to its use in the small quantities required for intramuscular injection. On the contrary, GLEYVOD maintains that it acts as an energetic cardiac stimulant in the febrile forms of pertussis, and those accompanied by much constitutional disturbance and severe pulmonary complications.

In spite of the enthusiasm with which a large number of French writers speak of the method, intramuscular injection of ether does not appear to have found general acceptance nor to be invariably successful, as so eminent an authority as Dr. JULES COMBY, of Paris, states that he has had an equal number of failures and successes. In the United States benzyl benzoate, which has been used for a variety of spasmodic conditions, has received enthusiastic support as a remedy for pertussis. From its use in 115 cases, the great majority of which were in children, Dr. DAVID MACHT, of the Johns Hopkins Hospital, has found[1] that the administration of benzyl benzoate solution, either alone or preferably combined with small doses of benzaldehyde, had a palliative though not curative effect on the violence and number of the paroxysms. Five to 40 drops of a 20 per cent. solution were given three or four times a day and oftener, according to the age of the patient and the severity of the disease. The beneficial action of the drug, according to Dr. MACHT, is due to a variety of factors, which include its antispasmodic effect on bronchial spasm, its sedative effect on skeletal muscle, its anæsthetic effect on the larynx, its expectorant properties, and its antiseptic action. Before the Société de Thérapeutique de Paris, at the last session, Dr. L. DUMONT read a paper on the value of adrenalin in whooping-cough,[2] and claimed constant success in relieving the symptoms and abbreviating the course of the disease with this drug. This treatment is not new, and has been advocated in this country, but we know of no recent reports on its utility.

Vaccine treatment, which at one time enjoyed a considerable vogue, especially in the United States, has not fulfilled the expectations entertained. Dr. R. G. FREEMAN, a well-known pædiatrist of New York, states that until lately he had been of opinion that vaccines did not modify the course of pertussis, and that he had never seen a case prevented by their use. Recently, however, he has observed good effects from the use of fresh vaccines in cases where vaccines three weeks old had no effect. In a disease so capricious as whooping-cough, especially when it attacks children of a nervous disposition, it is difficult to estimate how far the effect of a given treatment is due to suggestion alone. LEDERER has recently treated 25 cases of pertussis by painting the throat every two days with a 2 per cent. solution of silver nitrate, a method previously recommended by OCHSENIUS. In the great majority of cases good results were obtained, the paroxysmal stage being considerably shortened, the frequency of nocturnal attacks diminished, and long-standing attacks frequently cured. LEDERER attributes the success of this method to suggestion and not to a specific bactericidal action, and recommends that the treatment should be reserved for older children of a neuropathic disposition in whom the attacks have lasted a considerable time, but without any complications. In such cases his experience is that the method may produce an immediate cure. KLEINSCHMIDT, however, thinks that suggestion can be excluded as an explanation of the success which he obtained from the use of diathermy in a large number of cases, among whom the youngest child was only 9 months old. The question as to how long a case of whooping-cough should be isolated is of considerable interest, especially to the medical officers of schools or children's hospitals. Recent investigations have shown that the disease is most contagious in the catarrhal stage, and ceases to be contagious at all after the third week. Dr. COMBY, therefore, is of opinion that isolation for pertussis may be reduced to a maximum period of a month, and that it is unnecessary to wait for the complete disappearance of the whoop, which may last for several months. But the persistence of the whoop, however harmless to other children, is damaging to medical science.

Panel Prescribing.

AN insurance practitioner was recently invited by his panel committee to show cause why he should not be surcharged under the excessive prescribing regulations for ordering resinol on various occasions in the course of two months for a case of eczema rubrum in a patient who had been unable to work for two years. The bill ran into pounds; it was regarded by the committee apparently as a glaring case. The practitioner appeared at the inquiry and stated that he had tried the B.P. preparation unguentum resinæ without any effect, that the insured person had been treated at hospital for two years, and that he had cured him in two months. The panel committee thereupon decided that he had justified the use of an expensive preparation. A second case has come to hand of an insurance practitioner who, on being asked to attend an inquiry, resented the criticisms of his formulæ and declared his intention of giving his patients the cheapest drugs he could find. The result was that he had to attend an inquiry at a later date on the excessive number of prescriptions given to his patients and the high level of his total drug bill. A third case occurred in which the practitioner was written to because his individual prescriptions exceeded an artificial datum line arranged by his insurance and panel committees. When the whole quarter's prescriptions were scrutinised it was found that the total number of prescriptions was small, the average for each patient treated being less than two and the total drug bill well under the amount allowed for his list at an average of 1s. 6*d.* per insured person. These cases well illustrate the position with regard to the provision of drugs for the treatment of insured persons receiving medical benefit.

The Insurance Act requires that the patient shall receive proper and sufficient medicines for the adequate treatment of his condition. The task of deciding what is proper and sufficient for the case is of course placed upon the prescriber, and is subjected to the general opinion of the panel committee, should a prescription be criticised on account of its exceptional cost. By his terms of service a practitioner is required to order such drugs and prescribed appliances as are requisite for the treatment of any patient. Here again the responsibility is placed upon the practitioner to decide what is requisite, and should his ordering be called in question by the panel committee, he must be prepared to justify the decision he has made. Such an arrangement may appear irksome in some individual cases, but it does ultimately lead to a more careful consideration of the needs of the case before the prescription is written. Inasmuch as practitioners are required to order the medicines necessary for the treatment of their patients on official forms, and these also act as vouchers on which payment is made to the chemist, they are collectively responsible for the amount expended in each committee area in providing insured persons with the proper and sufficient medicine guaranteed by the Insurance Act. These accounts for drugs are paid in full, and the Treasury is directly interested in seeing that a proper control is exercised in the spending of the drug fund. Originally this fund was computed at 2*s.* a head for each insured person entitled to medical benefit, with certain additional funds for special grants in the event of epidemics or excessive sickness. With the great increase in the cost of drugs during the war—and only in the case of a few drugs has the high cost been relieved—and with additional charges for professional services on the part of pharmacists, it is increasingly difficult to provide adequate drugs for insured persons without exceeding the fund as originally estimated. In many areas the allowance has been exceeded during the last two years. In London, for example, it is now approximately 2*s.* 6*d.* per insured person in the area.

[1] THE LANCET, 1920, ii., 615.
[2] THE LANCET, 1921, i., 1244.

It is necessary that some machinery should exist for checking waste, and the present regulations on excessive prescribing appear to be a fair method of controlling expenditure. Possibly some practitioners do not fully appreciate the need to act up to their full responsibility under the terms of service, thus making it impossible for the charge to be brought against the Act that the medicines supplied are inadequate and inferior either in quantity or quality. The charge, when made, reflects on insurance practitioners who are failing in their duty. In practice it is found that an exceptionally high drug bill connotes carelessness in the frequency with which prescriptions are given and in the quantity of medicaments ordered. Instances are on record of an individual prescription supplying the needs of the rest of the family. Moreover, free prescribing may lead on to vicious drug habits, and it is for practitioners generally to increase the estimation in which their advice is held and to reduce to a reasonable dimension the abject faith in drugs so common in neurotics and hypochondriacs. A careful, well-conceived prescription, however costly, means more effective treatment, with a resultant shortening of the term of the illness and material reduction of the quantity of drugs taken. The contention that there is no leisure in a busy practice for such thought and consideration is tantamount to an admission that the quality of the work is being sacrificed, and the time may soon come when the remuneration will be based on the quality of the work done rather than on the quantity—as in the present scheme. If, however, the quality is improved—and there is good evidence to show that the service given to insured persons reaches a higher standard year by year, and if it is still found that the drug bill is generally exceeded, then the question of more adequate provision will arise. On the other hand, the present arrangements are sufficiently elastic for special grants to be made to so-called necessitous areas. Practitioners have a responsibility in seeing that their patients get the proper and sufficient medicine specified in the Act. With the responsibility goes the burden of justifying their orders to a committee of their colleagues, who are probably the best tribunal for deciding the matter. An admirable memorandum published by the London Panel Committee throws much light on the whole question of the drug tariff.

Annotations.

"Ne quid nimis."

THE THEORY OF RELATIVITY.

THE difficulties of travel successfully overcome by our distinguished visitor, Prof Albert Einstein, should stimulate those of us, who have hitherto been reluctant, to start our own journey into an unknown and difficult country full of dangerous curves, projections, and angles subtending monuments of even higher mathematics. Dr. Einstein's address at King's College last Monday evening gave his hearers an attractive glimpse of what they might expect. To those who now decide to sally forth a useful guide is at hand in the shape of a book by Mr. E. Cunningham, who expounds the principle of relativity with great clearness.[1] When the first edition of this book appeared no experimental confirmation of the Theory of Relativity had been made. In the interval two out of three predictions have been verified, and spectroscopists are at present engaged upon the outstanding one. For a full comprehension of the general bearings of the principle of relativity a knowledge of mathematics is no doubt essential, and Mr. Cunningham's book is not without mathematical expressions to which it is difficult always to ascribe a direct physical meaning; but this implies only that his lucid exposition will appeal to a wider public than that for which it is primarily written. To the physician skilled in differential diagnosis the mental processes involved in this science, and the mode by which the Theory of Relativity has been developed, must appear to have a certain resemblance. When physicists invoked the æther as a medium for the transmission of light, all went well until experiments, designed to show the drift of this æther past the earth in its motion, all yielded negative results. A way out of the dilemma was suggested by Fitzgerald and developed independently by Lorentz; this was that the length of a body was not an invariable quantity, but depended on the direction of its motion through the æther. The Electronic Theory of Matter bids one refer anything so fundamental in character back to the electrons themselves; this, however, as Mr. Cunningham reminds us, only throws the mystery one stage further back, for the final question remains as to why the electron should change its effective dimensions in just the required amount to account for the failure of all observations to show our motion through the æther. The theory here set forth is on a different plane from such physical laws as those embodied in Maxwell's equations embracing the electro-magnetic theory of light; it is a general mode of thought, and many readers will share Mr. Cunningham's surprise that the generalities of which he writes should suggest any precise experimental findings: that they explain outstanding discrepancies within the degree of accuracy possible by observation is sufficient reason for the value placed upon them. The Theory of Relativity, at any rate to some, has brought a different view-point to bear upon the general outlook of natural phenomena. In Mr. Cunningham's words: "The fact that we are able to make such an excellent guess at the form of the laws of nature by mere geometrical considerations leaves us with an uneasy feeling that we are looking at nature through coloured glasses, and are simply seeing those aspects of phenomena which are the easiest for us to appreciate. This, however, is the usual course of science, and it is something to feel that this most comprehensive of physical theories itself suggests that when our power of vision is greater we shall discover whole new realms of phenomena."

[1] Relativity, the Electron Theory and Gravitation. By E. Cunningham, M.A. Second edition. With diagrams. London: Longmans, Green, and Co. Pp. 148. 10*s.* 6*d.* net.

In conclusion, we may remind our readers of the admirable special number of *Nature*, which appeared on Feb. 17th, and was entirely devoted to brief expositions on Relativity by acknowledged experts.

PNEUMONIA IN THE U.S. ARMY DURING 1917–18.

DURING the winter and spring of 1917–18 an epidemic of measles, occurring among the troops quartered in the United States Army Camps, was associated with a great epidemic of a peculiar form of pneumonia caused by a hæmolytic streptococcus; the epidemic was characterised by indefinite physical signs, by dyspnœa of an extreme type, and by livid cyanosis. This type of pneumonia was easily recognised as distinct from that ordinarily indentified as lobar pneumonia, more particularly as certain other cases occurring simultaneously displayed definitely the usual features of this acute specific fever. In an historical survey [1] of the epidemic form of pneumonia, Professor W. G. MacCallum points out that there is nothing new in its manifestations. The relationship of measles to severe and fatal pulmonary inflammation has always been recognised. With a fair degree of probability such epidemics may be traced back to the 16th century; recognisable descriptions date from 1812 (James Low), and perfectly clear ones from Delafield in 1884. The condition studied by Professor MacCallum may be indentified with that familiar to British readers as "purulent bronchitis," the first descriptions of which were published in THE LANCET in 1917 by Hammond, Rolland, and Shore [2] working in France, and by Abrahams, Hallows, Eyre, and French [3] who simultaneously and quite independently were obtaining identical results at Aldershot. Professor MacCallum concludes, "From the anatomical description which is given [in the articles on "purulent bronchitis" referred to], it seems evident that the lesion is practically the same as that which we are about to describe for the epidemic in this country." He observes, however, that the prominence of the influenza bacillus, which the British writers emphasise, was not demonstrable to the same extent in America, and he prefers the term broncho-pneumonia to "purulent bronchitis" (or bronchiolitis), as he found "the whole lung including the framework and pleura to be promptly affected." Measles is, of course, not an indispensable antecedent; it lowers the resistance of the tissues to the secondary organisms, e.g., pneumococcus or streptococcus hæmolyticus, which are responsible for the serious complications, and its rôle may be fulfilled by micro-organisms recognised or at present unrecognised. Professor MacCallum, in the first fasciculus, deals exhaustively with the post-mortem appearances, and to a minor degree with the clinical manifestations, of the fatal cases encountered in this first epidemic, which occurred contemporaneously with the cases of "purulent bronchitis" described by the British workers. At the conclusion he adds that since his paper was sent to press another and much greater epidemic has occurred, with appalling mortality, of pneumonia, and the investigation with special reference to the pandemic is elaborated in the second fasciculus. The original disease in this epidemic has, to use his own expression, been spoken of as influenza. He is clearly sceptical as to the rôle of the *B. influenzæ* in this epidemic, adding that it is found in pure culture associated with a form of pneumonia which is practically identical with the interstitial broncho-pneumonia described in connexion with measles. He considers that the evidence to hand for incriminating the *B. influenzæ* as responsible for the epidemic is inconclusive, and he relies upon the existence of some ultra-microscopic virus, an opinion in which he will not lack support in many circles. However, Dr. John Eyre, who was prominently associated with the original research at Aldershot, and with the investigation of many of the subsequent epidemics scattered throughout the country, is apparently satisfied that it is not necessary to invoke the presence of this hypothetical virus to explain the phenomena noted.

Nevertheless, in whatever features the author diverges from workers in this country in his opinion of the relative rôles played by the *B. influenzæ* and other organisms, his papers are in the main confirmatory of the chief results which have emanated from them. Three features in his results call for special reference. In the first place, we note the remarkable incidence of empyema. In the 49 autopsies enumerated in the first fasciculus, empyema figures in no fewer than 33. In this connexion it must be remembered that the term empyema is not used in the strictly surgical sense of thick pus, for which in life resection of a rib would be indicated. The author himself refers to this point in stating that in the majority of cases a thin watery turbid fluid occupied the pleural cavity and that the patient rarely survived long enough for thick pus to develop. More than one British worker has been struck by the relative frequency of this and other pathological features in epidemics occurring in certain areas, with relative infrequency or total absence of the same features in epidemics simultaneously occurring elsewhere. In other words, local peculiarities are prominent, and in all probability this empyema incidence may be explained as a special feature of the organisms in the epidemic here described. Secondly, only in the rarest instances was a positive blood culture obtained from a streptococcal infection, and in these cases only immediately antecedent to death, although in every case the heart's blood invariably yielded a positive result. Finally, as denoting the exhaustive character of the investigation, we note that the microscopical examination of the testes exhibited in many cases a cessation of spermatogenesis, a peculiarity to which attention has not been directed in this country.

IONISATION METHODS OF X RAY MEASUREMENT.

IN the year following the discovery of X rays the electrical effect produced by them upon a gas—namely, the ionisation—was shown to be one of their most striking manifestations. The light which a study of these electrical effects has shed upon atomic and molecular structure has illumined a splendid page in physical science; it was these ionisation studies which led to the recognition and isolation of the fundamental unit of negative electricity—the electron—by Sir J. J. Thomson in 1897. Experimental investigations since this date upon the ionisation of different gases under various conditions have been of an elaborative character. The accuracy of the electrical method of measuring the intensity of a beam of X rays made such investigations possible, yet the use of this method for the many medical purposes where intensity considerations are of supreme importance has only come into effect during the last few years.

Perhaps the main reason for this is that the type of electroscope used in ionisation work is only an intensimeter and not a quantimeter. It measures at any instant the intensity of the radiation in question; it does not integrate this intensity over an interval of time and so give a quantity which could serve as a basis for dosage. This is exactly what is required in X ray therapy, and it is probably due to the fact that the Sabouraud pastille acted as an integrator that it has had such an extensive application. Useful as these pastilles have proved for the purposes of surface therapy, their limits of utility are reached when any considerable degree of filtration of X rays is effected, for it happens that they become less and less sensitive as the wave-length of the X rays is diminished, and so they fail to serve even as accurate indicators of intensity once a certain wave-length is reached. This is not a limiting consideration in methods based upon the ionisation produced, say in air, by X rays of different wave-lengths. Generally speaking, we may say that the electrical effects are proportional to the amount of energy expended in the air by the beam in its passage through it, and do not depend dominantly upon selective processes. This being so, if some method were devised by which the electrical effects could be added up as time went on, then the whole electrification could serve as a basis of X ray dosage; this has now been very largely accomplished and we may anticipate that the electrical method will come more generally into radiological use for therapeutic purposes. One of the first instruments constructed with this intent and suitable for direct medical use, was the ionto-quantimeter of Szilard in 1916. Since then various modifications and improvements have been effected, largely as a result of the requirements of deep therapy. Upon the basis of this type of instrument Seitz and Wintz have founded their method of estimating the dose of X rays reaching organs at a depth in the body; in their treatment of cancer of the cervix by X rays a part of the ionto-quantimeter is actually introduced into the cervix and a measurement made of the intensity of X rays being applied. Two recent papers, one by Schrumpf-Pierron in *Paris Médical* of May 28th, the other by Iser Solomon in the May number of the *Journal de Radiologie et d'Electrologie* give good accounts of the general utility and practicability of this mode of measuring the dose of X rays under various conditions of therapy.

[2] THE LANCET, 1917, ii., 41.

[3] Ibid., 377.

It is reasonable to anticipate that, when an electrical method has received the general sanction of approval, means will be taken to decide upon some unit of X ray energy which, while having a scientific basis for its determination, will be selected with some direct reference to the quantity used by radiologists in the treatment of disease. International recognition of such a unit would do much to coördinate the dosage determinations in X ray therapy throughout the world.

MOLLUSCUM CONJUNCTIVITIS.

ALTHOUGH it is well known that molluscum contagiosum may attack the skin of the lids, the occurrence of conjunctivitis due to this cause is not generally recognised. Dr. Harold Gifford and Dr. Sanford R. Gifford[1] of the Department of Ophthalmology of the University of Nebraska College of Medicine, state that during the last 15 years they have seen about a dozen cases, six of which they describe in detail, in which persistent irritation of the conjunctiva has been kept up by one or two molluscum nodules at the edge of the lids. In none of the cases was there any other evidence of the disease in the uncovered portions of the body, and the patients did not know of any other nodules of the sort, but they were not stripped for examination. In some of the cases quite a marked conjunctivitis of the follicular type was set up, with thickening of the folds, and in one case there was ulceration of the cornea. The mode in which the nodules cause conjunctivitis is hard to determine. That it is not extension of the inflammation from the skin is shown by the usual absence of such inflammation about the nodule on the skin itself. The purely mechanical irritation of the nodule would appear to be almost negligible in the cases in which it is not situated on the lid border but back among the eyelashes. The writers suggest that itching causes the nodules to be rubbed and that in this way some irritating secretion is carried into the sac which sets up the conjunctivitis. Treatment consisted in incising the nodules in typical cases and thoroughly expressing their contents with a ring forceps. In three cases in which the characteristic central umbilication was not apparent, and there were no other typical lesions present, the nodules were removed and found to be definitely molluscous. Though the symptoms were usually relieved quite promptly, in some cases changes were set up in the conjunctiva, which persisted for some time after removal of the irritating agent.

INDUSTRY AND CONTENTMENT.

ECONOMISTS, political and otherwise, sociologists, and psychologists are ever ready to reconstruct the State, but the social aspects of medical work are seldom appreciated even by our own profession. For the most part these self-appointed lay physicians forget that the health of the State is made up of the health of its constituent members and that no State can be healthy or think healthily unless its members are healthy. Only in one branch of medicine is there some inkling of this fundamental fact—namely, in industrial hygiene. A contribution to knowledge on the subject is contained in the latest report of the Industrial Fatigue Research Board,[1] which deals with labour turnover, a delicate barometer of industrial contentment or of unrest. This report should be read in conjunction with an earlier one written by Dr. M. Greenwood and issued[2] by the Medical Research Council before the Board was in existence. The findings, which deal with more ample data, are in close agreement with those of the previous investigations; they are mainly based on records compiled during war time at national factories, but data gathered from peace-time factories are also laid under contribution. The authors, Miss Broughton and Miss Newbold, point out the loss to a factory of a high rate of leaving among beginners due to the fact that on the simplest of operations workers do not reach a reasonable rate of output under six weeks, while for moderately simple repetition work three months is required. They are able to show that labour turnover is highest in these early weeks and months; curves showing the rate of leaving distributed according to length of employment resemble in an exaggerated form the curve of infant mortality—indeed, Greenwood has aptly called labour turnover the infant mortality of industry. The medical aspect of this important social economic question becomes manifest when the connexion between labour turnover and sickness is investigated; here the authors found that those who left with less than three months' service had suffered a much higher rate of sickness than those who stayed longer, that those who stayed for three months but less than six had suffered throughout their period of employment more sickness than those who stayed longer, and similarly that those who stayed six months but less than nine had suffered more throughout than those who still remained in service. Ill-health and physical incapacity were only given as the reason for leaving by some 10 per cent. in war time and by 3·7 per cent. in peace time, but the above investigation showed that even though hardly appreciated by the workers, ill-being lay at the back of much labour wastage.

Most of the records used refer to female employment, and somewhat unexpected results emerge; thus domestic servants, shop assistants, and laundry workers stayed longer than workers from munitions and other factories. Apparently factory work has a definite adverse influence on the power of workers to withstand the strain a second time. Comparison is made between the rates of labour turnover which prevailed before, during, and after the war; for single women the average three-monthly rates of leaving were found to be 25·2 per cent., 27·8 per cent., and 18·8 per cent. respectively for the three periods. The rate of loss during the first three months was specially heavy, amounting to 45·3 per cent., 39·6 per cent., and 22·0 per cent. in the three periods. The post-war period was favourably influenced so far as leaving is concerned by the fear of loss of work due to men returning from the colours and filling up vacancies. Some estimate can be made of what these rates of leaving mean from the fact that " in the pre-war and post-war periods respectively, the number of survivors after 12 months from 1000 entrants in a biscuit factory were 322 and 441 respectively." Great differences were found at different factories, the rate of loss at the end of the first three months varying from 89·2 per cent. to 37·5 per cent., but the influences causing these variations could not be accurately determined. Nevertheless the authors state that at the factory with the lowest labour turnover the conditions were good and the work light; while at one of the worst the high turnover was considered to be " due undoubtedly to the arduous conditions, and in a large measure owing to night-shift working, the ordinary disadvantages as to broken rest being aggravated by the shops being built of corrugated iron with consequent extremes of temperature."

[1] A Statistical Study of Labour Turnover in Munitions and other Factories, by Miss G. M. Broughton and Miss E. M. Newbold. Report No. 13. Industrial Fatigue Research Board. 1921. Pp. 92. H.M. Stationery Office. 3s.

[2] A Report on the Causes of Wastage of Labour in Munitions Factories employing Women, by Dr. M. Greenwood. Special Report Series No. 16. Medical Research Council. 1918.

Great care is exercised throughout this excellent report in refraining from drawing any but fully substantiated deductions; hence even more than usual reliance can be placed on the following conclusions:—

(*a*) The high leaving-rate that is evident in the early months of service is not confined to munitions factories nor to the war period, but is also to be found in factories engaged in peace-time industries, and is a source of economic loss at the present time.

(*b*) Married women are evidently a more fluctuating population than single women.

(*c*) The data relating to previous occupations are also too scanty to justify drawing general conclusions, but they indicate that former factory or munition workers are more unstable than those drawn from other sources.

(*d*) The loss for possibly avoidable reasons, such as ill-health, incompetence, and dissatisfaction, is very large.

The authors justly consider a case made for periodical consideration by employers of the state of labour turnover in their factories; and in order to assist the work, give in an appendix specimen forms for keeping records, and a simple exposition of the way in which they can be used. Special attention may be directed to the excellent form of medical certificate suggested in which the system of the body affected (rather than an exact diagnosis) is all that is asked for, as, indeed, it is all that could ever be usefully employed for statistical grouping. We agree with the Fatigue Board, who claim that " the attempt made in this report to measure labour wastage upon a uniform system, essentially similar to that adopted in the valuation of the liabilities of life insurance offices, deserves consideration"; and we congratulate them and the authors on having in this report added something to knowledge.

THREADWORMS AND APPENDICITIS.

VARIOUS workers have ascribed a share in causing inflammation of the appendix to threadworms. Prof. L. Aschoff,[1] of Freiburg i.B., opposes the view advocated by Rheindorf that oxyuris bear a frequent ætiological relation to acute appendicitis. Aschoff holds that appendicitis begins nearly always as an acute disease in a previously healthy appendix, passing after imperfect healing into a chronic complaint. The earliest lesion is commonly found in the deeper folds of the distal part of the appendix, and mechanical causes, by leading to undue delay of bacterium-infected material in contact with the mucous membrane, favour disease; but direct injury of the mucous membrane by foreign bodies or parasites is uncommon. Worms may give rise to pseudo-appendicitis or appendicopathia oxyurica—that is, a condition simulating appendicitis but without pyrexia or much quickening of the pulse-rate. They are found in healthy appendices more often than in diseased ones. Gmelin found that 19 per cent. of 300 patients in a field hospital were infected with oxyuris, and 19 per cent. with trichocephalus. Forty-four per cent. in all carried the eggs of some worm. Among these patients 18 cases of appendicitis occurred, of which only five—that is, less than a third—were in the worm-infested. Encapsuled threadworms may occasionally be seen in the appendical wall; but the histological appearances described by Rheindorf of channels in the mucous membrane made by worms boring into it and other epithelial defects are caused by the dehydration and other procedures connected with the preparation for the microscope. Such epithelial defects are found in sections of all appendices, healthy or diseased, made by the usual methods. If worms are present further artificial defects are caused by the pressing of their chitinous coats into the epithelium when cutting. Such appearances are not seen if the tissue is protected from shrinking by embedding and cutting in celloidin or gelatin. Further, a superficial catarrhal inflammation must not be assumed to be present unless there is migration of cells. Aschoff supports his thesis by statistical and histological detail, and with some warmth. He has laid his material, including sections embedded in various ways, before a medical congress and challenges his opponent to do the same.

THE INDIARUBBER-BALL COUGH SOUND.

WITH a thoroughness which is characteristic of the medical school of Upsala, Dr. G. Bergmark[1] has recently investigated the conditions under which the indiarubber-ball cough sound arises. Thus named by Dr. J. Mitchell Bruce, this post-tussic suction sound has been interpreted by some authorities as a sign of a cavity, on the assumption that it is generated by the elastic recoil of the wall of a cavity. Dr. Bergmark found this sign in 20 out of 39 cases in which the diagnosis of cavitation was confirmed by a necropsy. He failed to find it once among the 40 young and healthy persons whose chests he examined for it. In 35 cases of acute bronchitis, and in 52 of chronic bronchitis, he failed to find this sign, although in 18 cases the bronchitis was complicated by emphysema. The 12 cases of bronchial asthma examined for this sign, failed to show it. It was also negative in every case but one out of 42 in which the diagnosis of bronchial gland tuberculosis had been made by the X rays. In Turban's first stage of pulmonary tuberculosis it was never found, and only in 3 of 36 cases in the second stage was it demonstrable, whereas it was found in as many as 56 out of 130 cases in the third stage. Of a series of 25 cases of pulmonary tuberculosis associated with bronchophony or coarse râles, the sign was found in 16. In another series of 25 cases, in which the sign was positive, 20 exhibited bronchophony or coarse râles. With regard to the post-mortem examinations, no correlation could be established between the size and distribution of cavities on the one hand and the presence of this sign on the other; in two cases in which there had been a suggestion of the indiarubber-ball sound. the necropsy showed no sign of a cavity on the same side. But as there were cavities on the opposite side, this sound may have been conducted from one lung to the other. In view of the possibility that infiltration of the lung without cavitation might give rise to this sign, Dr. Bergmark sought it in 47 cases of croupous pneumonia, but found it only in one in which the pneumonia was complicated by pleurisy. In another series of 77 cases of broncho-pneumonia, he found the sign only in one case, and here again it was complicated by pleurisy. Thus, it appears that infiltration alone is not sufficient to give rise to the sign. It seemed, however, possible that pleurisy, by interfering with the elastic recoil of the lung, might give rise to the sign in the absence of cavitation; in 47 cases of pleurisy 5 exhibited this sound. Dr. Bergmark comes to the conclusion that though cavitation is the chief factor in the genesis of this sign, its appearance may be determined by the presence of pleural adhesions over a cavity. If this is so, the absence of the sign over a cavity may be helpful as indicating the absence of adhesions in the neighbourhood, promoting the successful induction of an artificial pneumothorax.

THE NERVOUS RESPONSE TO STIMULATION.

IN the course of a lecture at the Institute of Pathology and Research, St. Mary's Hospital, on June 9th, Dr. Henry Head said that the thalamus was now definitely proved to be the seat of the affective side of consciousness, a sorting of stimuli taking place here before the final result reaches the cortex. This sorting, rearrangement, and elimination took place not only in the thalamus, but at lower levels as well, the various centres of brain and cord forming as it were a nervous heirarchy. Only the dominant cortical centres are, he said, concerned in consciousness, the exact message they received depending on modification by the lower centres of the crude mixed stimuli arising from the end-organs. The selection of some messages and the suppression of others depends not only on the nature of the stimulus, but also on the condition of the receiving and transmitting mechanism, which may be profoundly modified by previous stimuli or by alterations in the environment. The organic neurologist, said Dr. Head, regards the nervous system as a penny-in-the-slot machine, into which we could put a penny with the certainty that a box of matches would emerge; but in the light of the new physiology it was obvious that one might equally well get chocolates, the result depending not so much on where the penny was placed as on who had been there before. The doctrine of specific nerve energy still apparently holds good, if we remember that a given stimulus may lead to different results under different circumstances. For example, pain is a necessary ingredient of *every* cutaneous sensation since it is a primitive protective factor and the organism cannot afford to eliminate it. If an object—say a test-tube containing warm water at 45° C.—is placed next to the skin the only sensation that is allowed to reach the higher centres is that of pleasant warmth. Heat, cold, and pain spots are severally stimulated, but the messages are incompatible and the strongest wins. This degree of heat being beneficial and not harmful, the impulse of pain may safely be inhibited. Dr. Head compared the central nervous system to a telephone exchange where only certain calls are taken. Pain, except when necessary as a warning, receives no attention. That pain is always an ingredient is shown by an observation made by Dr. Head himself during a well-known experiment on his own radial nerve. At one period of its regeneration any stimulus applied to the base of the index finger was referred to the outer side of the thumb. If the thumb was then stimulated with pleasant warmth and the index finger with icy cold the hot and the cold sensations neutralised each other and the net result was pain. In this case it was as if the favourite and the second favourite of a race came to grief, the rank outsider, pain, arriving first. This selection by suppression, repression, and facilitation of certain impulses depends for its final result on various factors, the chief being the nature of previous stimuli and the condition of the nervous system, and indeed of the body as a whole. For example, all normal persons become giddy if subjected to rapid rotation, but with repeated practice this tendency may be to a large extent overcome, only to return again in conditions of toxæmia, mental depression, worry, or fatigue. Dr. Head defined physical exhaustion as the loss of capacity to dominate impulses derived from peripheral stimuli; and he regarded as one of the most important landmarks in physiological research the discovery that even at the lower end of the spinal cord these same processes of facilitation and suppression could be demonstrated to occur.

THE SCHICK TEST AND NATURAL DIPHTHERIA ANTITOXINS.

THE Schick test[1] has hitherto made a much wider appeal to clinicians and immunologists in America than it has in this country. In a paper recently read before the Pathological Section of the Royal Society of Medicine by Messrs. A. T. Glenny, K. Allen, and R. A. O'Brien, and published in THE LANCET of June 11th, an appeal is made for a closer study of this reaction in Great Britain. The test is based upon the fact that small quantities of natural antitoxins appear to be present in the blood of normal persons. When one-fiftieth of a minimum lethal dose of diphtheria toxin is injected *intradermically* into a normal person it is neutralised by the natural antitoxin present in the blood, and no reaction follows. If, however, a person possesses no such natural antitoxin, the toxin injected will produce a reddened local reaction at the site of inoculation. This reaction is apparently purely an inflammatory one, and is not in any way related to the local reaction produced by Mantoux's intradermic tuberculin test, which depends on hypersensitiveness or anaphylaxis. A negative test therefore indicates some degree of natural immunity to the Klebs-Löfller bacillus, whilst a positive result signifies susceptibility. The authors of the present paper have made a careful laboratory study of the reaction, and indicate its probable usefulness in controlling an outbreak of diphtheria in a school or hospital. It would appear from the published results of Schick himself, and of Kolmer[2] and others in America, that it may be especially useful in young children in whom the question of immunisation is urgent. The authors also indicate certain issues which are of practical importance: (1) The preparation and control of toxicity (m.r.d.) of the test serum, which is, of course, primarily a laboratory matter; and (2) the interpretation which must be placed upon certain "pseudo-positive" and "combined" positive results. The latter raises, as the authors point out, certain very interesting questions as to the toxicity of bacterial proteins which need to be worked out by clinicians and immunologists conjointly. They also go on to discuss the bearing of this reaction in relation to von Behring's toxin and antitoxin ("T-A") method of immunisation.

In the number of the *Bulletins et Mémoires de la Société Médicale des Hôpitaux* of April 14th a series of articles on the Schick test by various authors give results of similar clinical observations on numbers of cases in a school and preventorium. The practical consequence of these various observations needs little emphasis. The use of the Schick test combined with von Behring's "T-A" method of immunisation may yet revolutionise the treatment of diphtheria in school and hospital epidemics. If, in addition, it will help to clear up the hopeless confusion at present existing on the question of diphtheria carriers it will be no small blessing to civilised communities where overcrowding is bound to occur and infection commonly results. The theoretical issues from the point of view of the immunologists are no less arresting, and we shall watch with interest the study of this question, not only with the toxin of *B. diphtheriæ*, but with all those toxins which Ehrlich associated with the toxin-antitoxin phenomenon in his first order of side-chains. Whatever be the truth of the matter with regard to this theory the classification of certain immunological phenomena into groups according to the different reactions of antigens and antibodies is doubtless of much significance.

AN INSTITUTE OF APPLIED MEDICINE.

THE governing body of the Lister Institute presented this week its twenty-seventh annual report to the annual meeting of subscribers. It is a fine record of applied medicine, rendered possible largely by the prophetic vision of Joseph Lister and the wise generosity of Lord Iveagh. In the department of bacteriology Prof. J. C. G. Ledingham has continued his investigations on the transmission of the virus of trench fever. Dr. J. A. Arkwright has concluded his work on bacterial variation, and Dr. H. L. Schütze has shown the possibility of determining the blood group of an individual from a dried sample of his blood, a matter of great importance in medico-legal practice. Dr. E. H. Lepper's research on coliform infections of the urinary system may have a practical bearing on cystitis in the human subject. In the department of biochemistry Prof. A. Harden and Dr. S. S. Zilva have continued their work on accessory food factors, some of the results of which have already been made public through our own columns; and a group of investigators under the guidance of Dr. Harriette Chick are putting into practice the logical deductions from this work in Vienna, where the matter is of more than theoretic interest. The national collection of type cultures, placed at the service of bacteriologists throughout the Empire, continues to grow, and a catalogue of the cultures will shortly be published by the Medical Research Council. Sales of tuberculin and immune serums realised during the year a sum of £53,700, while the income and expenditure account for the financial year shows a substantial balance on the right side. This is the more satisfactory as the item of £19,600 for staff salaries and wages suggests that those who have given their lives to research work for the benefit of their fellows are receiving more than the miserable pittance which is often their only material reward.

TUBERCULOUS ANTIGENS IN URINE.

IT is two years since Dr. Hans Wildbolz of Berne first published[1] the interesting observation that urine from a tuberculous patient, evaporated to one-tenth of its volume and filtered, gives a typical allergic cutaneous reaction when injected intradermically, after the method of Mantoux, into another tuberculous patient. This original observation has been confirmed by Gramen, of Stockholm,[2] and others. Quite recently Dr. M. G. Ichok discusses[3] the whole question of tuberculous antigens in the urine at some length, and gives also brief details of tests made in rabbits. He points out that though it has been left to Wildbolz to make use of the presence of tuberculous antigens in the urine as a clinical test, isolated observations had been made by Marmorek as long ago as 1909 and by Biot in 1914. This test, in Switzerland at any rate, now appears to have acquired a position of clinical importance.

Dr. Ichok's article is suggestive. Apart from chemical questions involved, such as the effect of phosphates and oxalates on the skin reaction, there are at least four possibilities to be borne in mind from the point of view of immunity: (1) The presence of toxic substances excreted in varying amounts in the urine of all tuberculous subjects; (2) the excretion of special degeneration products of unknown composition in the urine of patients with lardaceous disease; (3) the elimination of living or dead tubercle bacilli in the urine of phthisis patients, which is known to occur from time to time apart from the presence of gross lesions in the kidneys; (4) the presence of casts, cellular and bacterial elements (not only tubercle bacilli, but secondary organisms) in the urine of cases of genito-urinary disease. Even if we assume that the process of concentrating the urine to a small bulk by evaporation at 55° C. indirectly sterilises it, there are obvious reasons for only using for the test the urine of early tuberculous cases uncomplicated by genito-urinary disease. Dr. Ichok's article seems to us to offer a fairly accurate method of estimation. After examining the urine microscopically in order to be sure that it contains no products of gross renal lesions, he inoculates the urine, concentrated in the usual way, subcutaneously into rabbits. These animals are found subsequently to develop tuberculous antibodies, which can be detected by fixation of complement.

SECURITY OF TENURE FOR M.O.H.'S.

THE Public Health Officers Bill passed a third reading in the House of Commons on June 3rd. The original intention of the Bill was to give all full-time medical officers of health and sanitary inspectors security in the tenure of their office. The Bill was, however, amended in Committee, so that it is now limited in its application to those officers a portion of whose salary is paid by the Exchequer. There is a further limitation that it shall only apply to the senior sanitary inspector employed by a local authority. The amendments will cut out from the benefits of the Bill a considerable number of medical officers and many sanitary inspectors. Sir Philip Magnus, the introducer of the Bill, agreed with the arguments of those who wished the Bill to apply to all whole-time officers, but had to make concessions to those authorities who had bought their freedom by refusing to accept Government grants, in order to get the Bill through. It was better, he said, to have four-fifths of a loaf than no bread. Considering the large number of sanitary inspectors employed by the county boroughs, we shall be surprised if the Bill applies to more than a tenth of the sanitary inspectors in the country. Theoretically, one cannot gainsay the argument that a medical officer of health or sanitary inspector ought to be in a position to carry out his work for the protection of the public health without the fear of dismissal if his work happens to bring him in opposition to influential members of the local authority which employs him. In practice it may be true, as Sir Kingsley Wood stated during the discussion, that there have not been a great many cases where the medical officers have suffered at the hands of the local authorities, but who is to know in how many cases the medical officers have felt it advisable to give way? A conscientious official who is keen on his job, and feels that he is doing good work, may be pardoned for thinking that it is advisable to take the line of least resistance in a few of such cases, provided he is getting the support of his committee in the execution of the most important sanitary reforms which he has to bring before them. Medical officers of health are not all Don Quixotes, and some will take the line of least resistance more easily than others. To give an illustration, it is conceivable that the examples of the so-called conservancy system, which still disgrace the sanitation of many of our county boroughs, would have disappeared years ago if medical officers of health had had greater security of tenure. We can easily understand the attitude of the local authorities. The bulk of their members respect the advice of an efficient officer, and treat him fairly. They are genuinely interested in the sanitary improvement of their district. They feel that they are able to manage their own affairs without the interference of Government departments which has been so much in evidence lately. "Timeo Whitehall et dona ferentem" was fast becoming the attitude of the local authorities. We believe, however, there are signs of a change, and that the local authorities may safely trust the Ministry of Health in this matter of security of tenure for public health officers. Our only regret is that the Bill does not, as originally intended, include all whole-time officers, and we hope that what Sir Philip Magnus calls the other fifth of the loaf will be forthcoming *during an early session of Parliament.*

THE BRONCHO-PNEUMONIA OF OLD PERSONS.

THE frequency of pneumonia and broncho-pneumonia as a final cause of death in the aged is well known. Charcot has related how insidious the onset of pneumonia often was amongst the aged inmates of the Salpêtrière Hospital at Paris. Drs. G. Roussy and R. Lerou[1] have recently published an anatomical-pathological investigation on the subject of broncho-pneumonia of the aged, founded on the material furnished by their department for old persons at the Hospice Paul Brousse at Villejuif. Amongst 300 post-mortem examinations (1919–21) they found lobar pneumonia in 4 cases and broncho-pneumonia in 162 cases. According to their elaborate macroscopic and microscopic examination of the lungs, there are frequently basal lesions of the nature of chronic arteritis and pulmonary sclerosis playing an important part in the production of the broncho-pneumonic condition. The lesions in question lead to the occurrence of a complete or partial vascular thrombosis, with ischæmia and even necrosis, more or less complete, of the corresponding portion of the pulmonary parenchyma. A secondary microbic infection then takes place, and it is easy to understand that the secondary infection of an infarct in the lungs is more likely to occur than of one in the kidneys or brain. The authors claim that their aspect of the matter enables us to understand the frequency of fatal broncho-pneumonia among bed-ridden persons, suffering from cerebral arterio-sclerosis. According to them, the idea of hypostatic congestion of the lungs fails to explain why such patients can keep to their beds for years without suffering from pulmonary complications, suddenly to be carried off by fatal broncho-pneumonia.

THE DRY METROPOLIS.

THE Metropolitan Water Board has intimated to the Ministry of Health that in consequence of the prolonged drought it is necessary at the present time to conserve the water-supplies of the metropolis, and a circular has been issued to sanitary authorities suggesting the restricted use of water for such purposes as flushing sewers or watering streets and recreation grounds. Drought does not strike like lightning and there has been ample warning that London will be short of water this summer. Thames water provides nearly 60 per cent. of the total supply, the Lee coming second with 23 per cent., well-water only yielding the small remainder of 17 per cent.; and during the month of March the average daily natural flow over Teddington Weir was, in round figures, 890 million gallons, or 1230 million gallons below the daily average of the last 40 years. In the same month the rainfall of the whole Lee basin was under 1 inch, and the months before and since have been equally dry. The river reservoirs with their immense storage capacity of nearly 13 thousand million gallons may seem inexhaustible, but with the normal demand they would give out in 50 days; and the band of chalk under the London clay, although full of water like a sponge, only yields what the pumps are capable of raising. Not since 1899 has there been any such drought. We are better off now than then, for the precious fluid is no longer vended to us by a number of competing companies with the interests of shareholders to consider, and timely notice of the shortage will have been given to the Ministry whose business it is to decide in what directions economy may be practised without danger to the public health. Thirty-eight gallons per head, per day, the normal rate of consumption, leaves a wide margin for luxury and waste. The public would like some guidance on where and how to save water if and when the need arises. Drainage by water carriage is so automatic and fool-proof, street-cleaning by the sanitary authority so regular, that the average citizen develops little personal sense of responsibility for keeping his city clean and sweet. We confess to some misgiving, however, about the economies suggested for a start. The normal sewer flush may be excessive; the Ministry of Health doubtless knows that it is. But to limit street watering just when the season of zymotic diarrhœa is beginning—that is open to question. In 1899 no one could define the effect of drought on the public health; was it the heat, the dirt, or the dryness of the subsoil that was the potent factor? We are not much wiser now; the spectre of epidemic diarrhœa may again overshadow London should July be hot as well as dry. There may be the same spike on the infant mortality chart for 1921 as there was in the hot summer of 1911. Until we have proved that watering the narrow crowded streets does *not* help to keep away summer diarrhœa we are hardly justified in economising there, rather than on baths and leaky taps. The thoroughfares with a minimum of horse traffic and a top dressing of petrol and lubricating oil may probably be left safely to take care of themselves.

PUBLIC HEALTH AT THE LABOUR CONFERENCE.

THE British Labour Party with its three million members, who for the most part are trade-unionists and voters, holds its annual conference on June 21st at Brighton. Though the conference sits for only four days, the agenda paper gives the text of no less than 248 resolutions and amendments, many of them dealing with world politics, diplomatic questions and recondite economic problems, which even the keenest intellects of the day might find it hard to grasp. Only towards the end of the agenda do we reach the question of education, when the Northampton Labour Party is to demand better treatment of school children's teeth, and complains of the almost total lack of any provision for such serious physical defects as spinal curvature, pigeon chest, and of the insufficiency of nursery schools and open-air schools for delicate children. Twelve proposals on the drink problem all, in one form or another, condemn existing public houses. The Carlisle experiment seems to meet with most approval, the sale of drink only being tolerated where food is provided as well as facilities for social intercourse. Several resolutions demand local option and State control of the trade in alcohol. On the housing difficulty, the executive committee has a resolution denouncing the Government for obstructing, during the last two and a half years, the erection of the half million new houses it had promised. The Government is admonished itself to supply the needed material and thus break up profiteering combinations. The Stepney Trades Council proposes the rationing of house accommodation and the stopping of superfluous house building—namely, luxurious dwellings—while others are forced to live in hovels unfit for human habitation. In regard to old age and other pensions, a number of resolutions are tabled to increase the amounts given, several Trades Councils endorsing a scheme for a State bonus to replace existing organisations for providing subsistence in cases of distress by a national pool collected from the national income at its source. The Poor-law, we imagine, itself disappears in the pool. Demands for better organised and more extensive help to mothers and to widows who have the charge of families are perhaps more likely to find immediate acceptance. In fact, the endowment of motherhood, on a more or less extended scale, has already entered the domain of practical politics. With regard to the Workman's Compensation Acts, a resolution advocates compensation for accidents on the same basis as that upon which war pensions are granted; another urges that the schedule of industrial diseases should be extended so as to include coal miners' asthma and other diseases caused or aggravated by the occupation on which workmen were engaged 12 months before they were disabled. Finally, we notice that the National Union of Ships Stewards, Cooks, Butchers and Bakers have come forward with a demand to be included in the advantages already granted to seamen and firemen. One resolution which deserves to be quoted, runs: "In view of the alarming increase of consumption among seamen, this Conference demands an inquiry into the living accommodation provided on board ships." Such are the principal proposals affecting public health, unfortunately smothered in the midst of a political programme of appalling length and complexity. Laws are of little avail if they are not understood and approved by the community, and we rejoice that the Labour Party is turning to the study of health legislation. It is to be hoped that by next year the political situation will have so improved as to enable these matters to be more fully discussed than on the present occasion.

---

HEALTH OF TROOPS IN THE PALESTINE CAMPAIGN.

General Liman von Sanders, in his apology[1] for the defeat in 1918 of the Turkish Army Group which he commanded in Palestine, urges in extenuation that "there was a great epidemic of disease during the summer months, malaria and dysentery taking a heavy toll of the armies." It was known this must have been so, but it is satisfactory to have it stated by authority, and it shows that in this, as in all wars, a medical service which is ineffective lowers the fighting efficiency of the troops it is supposed to serve. Further, the statement supports the opinion we have already expressed that Lord Allenby's skilfully planned and magnificently successful operations on Sept. 19th, 1918, could not have been set going—there would not have been the troops to make them possible—but for the excellent work of the Royal Army Medical Corps, which planned the anti-malarial measures in the Auja Valley, and so kept the loss of strength from malarial fevers in Palestine, in the worst sector, down to 10 per cent. of the troops in the four months preceding the great attack.

THE Census, which was postponed last April, will be taken next Sunday, June 19th. The names of those dying before midnight on Sunday or born after midnight must be omitted.

THE William Gibson Research Scholarship (Second Award) for medical women has been awarded by the Council of the Royal Society of Medicine to Miss Gertrude M. A. Herzfeld, F.R.C.S. Edin.

THE first British Congress of Obstetrics and Gynæcology, held in Birmingham on June 3rd and 4th, was attended by delegates from societies in Edinburgh, Glasgow, the Midlands, the North of England, as well as from the Royal Society of Medicine. We hope to give an extended notice of this very successful meeting.

THE annual general meeting of the Research Defence Society will be held at the house of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, on Wednesday, June 29th, under the presidency of Lord Lamington. A short address will be given by Dr. H. H. Dale, C.B.E., F.R.S., on the Work of the National Institute for Medical Research.

THE POSITION OF THE VOLUNTARY HOSPITALS.

REPORT OF LORD CAVE'S COMMITTEE.

THE Report of the Committee on Hospital Finance (Lord Cave's Committee) appeared last week, when we published the recommendations. We comment on these in a leading article. An official summary of the document runs as follows:—

1. The present financial difficulties of the hospitals are due to the war. The receipts from voluntary subscriptions, donations, and legacies have not fallen off—on the contrary, they have risen by 67 per cent. since 1913. But during the war the cost of provisions, drugs, dressings, fuel, and labour has increased to such an extent that the expenditure of the hospitals has increased by 188 per cent. since 1913. The aggregate deficits of all the voluntary hospitals of Great Britain for the present year are estimated at £1,000,000 (para. 8).

2. The voluntary system is, therefore, temporarily in jeopardy. The Committee ask, "Is the voluntary system worth saving?" and their conclusion is, "We are convinced that it is." Apart from the immense sum of voluntary subscriptions and donations (estimated at £3,000,000 a year), the voluntary system secures gratuitous and skilled service, both lay and medical, of inestimable value. It preserves freedom in medicine, and is of incalculable advantage to the welfare of the sick, the training of the medical profession, and the progress of medical research. The breakdown of the voluntary system would imperil these services and impose a constantly growing charge upon public funds (para. 15).

3. The Committee are of opinion that if the voluntary hospitals are to be saved immediate assistance must be given by the State, such assistance to be strictly limited to a definite period of two years, and to be given only to hospitals which show that they are taking all possible steps to re-establish their financial position. A grant so limited and conditioned would re-establish the hospitals in the self-supporting position which they occupied before the war, and would not be inconsistent with the maintenance of the voluntary system (para. 16).

4. The Committee draw attention to a number of steps which managers of voluntary hospitals can themselves take to improve the financial position of the hospitals under their charge—e.g., review of expenditure, particularly in the light of comparative costs which could be ascertained by the general adoption of a uniform system of accounts (paras. 24 and 25); coöperative buying of drugs, apparatus, stores, and some kinds of provisions (para. 26); removal of convalescent cases to auxiliary hospitals (para. 27); coördination of appeals for subscriptions (para. 28); further development of new sources of income, such as subscriptions from wage-earners and employers, and other contributory schemes, examples of which are quoted in the Report (paras. 29 to 40); contributions from Approved Societies (para. 43).

5. To give effect to the temporary State assistance the Committee make the following recommendations:—

(1), (2) That a Hospitals Commission and Voluntary Hospitals Committees be formed for the country as a whole, the King Edward's Hospital Fund for London continuing to perform the functions of the latter for the Metropolitan Police District.

(3), (4) That Poor-law guardians be authorised to enter into arrangements as to the use of infirmaries, and that county councils be empowered to contribute to the expenses of voluntary hospitals committees.

(5) That failing the provision in the National Health Insurance Acts of a "hospital benefit," the courts be authorised to award to hospitals compensation under the Employers' Liability and Workmen's Compensation Acts.

(6) That local authorities be authorised to pay the cost of the treatment in hospitals of persons in their employ.

(7) That the payment out of technical education funds of grants for the training of nurses be considered.

(8) That provision be made for obtaining and tabulating returns of cases treated in hospitals.

(9), (10), (11) That all contributions by employers to hospital funds be allowed as deductions from profits for income-tax purposes, that where the payment to a hospital of a testamentary gift of residue is delayed for more than a year, the hospital be authorised to claim repayment of income-tax, and that legacy and succession duty on testamentary gifts to hospitals be remitted.

(12) That Parliament be asked to sanction a temporary grant of £1,000,000 to be expended under the direction of the Hospitals Commission in the assistance of hospitals which require it.

A last clause states that the Hospitals Commission should be authorised during a period of two years to recommend grants for the extension and improvement of hospitals subject to like contributions being made from private sources.

These recommendations if adopted will require legislation or executive action.

MEDICINE AND THE LAW.

The Certification of Lunatics.

IN a recent action tried by Mr. Justice Bailhache, sitting with a special jury, J. R. Gore Brown sued Sir Maurice Craig and Dr. J. Pitcairn, medical officer of Wandsworth Prison, for damages for conspiracy, false imprisonment, and wrongfully certifying him as a criminal lunatic, in consequence of which he was confined in Berkshire County Asylum. After an adjournment for several days in order that witnesses might be called to prove the authorship of a letter produced by the plaintiff, and alleged by him to have been sent by Sir Maurice Craig to the medical officer of the asylum in which the plaintiff was confined, the promised witnesses were not forthcoming, and the jury found for the defendants. The plaintiff's account of a career in which he had been military governor of Sonora, a general in the Mexican forces, and military adviser to President Carranza, of his military services in the war and his adventures with a German spy, has been fully reported. He appears, according to his own account, to have been sentenced to imprisonment upon a charge of dishonesty, and afterwards confined as a lunatic. The letter which, he alleged, was written by Sir Maurice Craig in connexion with this incident began with the sentence: "Dear Sir, In reply to your letter of December 10th in reference to the case of John Radleigh Gore-Brown, it is imperative that he should not be discharged from your asylum at the present time. There is no doubt of his sanity, but there is, as you can undoubtedly see, a very specific reason why he should not be set at liberty—he is a most dangerous man, and is a member of an Esoteric Eastern Order, which have as their object the downfall of the British Empire." There was a good deal more in a similar strain, and in his summing up Mr. Justice Bailhache observed on the internal evidence pointing to it not having been written by Sir Maurice Craig, and suggested that if he had written it he would himself be a fit subject for a lunatic asylum. That the trial should have occupied a judge and a special jury for two days, with an interval of postponement for the plaintiff's benefit, is no doubt creditable to our judicial system, as showing the impartial fairness of our courts, and the unwillingness of our judges to place the plaintiff in person at any disadvantage. Such a case, however, inflicts great and undeserved hardship upon medical men who perform duties essential to the safety of the public and of the individual whose sanity is questioned. Trials in which persons who have been confined in asylums seek for damages are, moreover, frequent. Such unfortunate individuals deserve sympathy rather than condemnation in their resentment at treatment, the necessity for which they do not understand. But the persons against whom they bring actions deserve sympathy still more. A measure of protection that could be afforded to them would be to enable the person confined to appeal within a certain time after his admission to an asylum to an official expert, whose pronouncement on his case should have the finality and privilege enjoyed by a judge of the High Court trying a question of fact. If no action could be brought against such an authority in respect of anything done by him in the performance of his duty, or against any other medical man without his sanction, the medical man consulted in a case of alleged insanity would escape, not the liability to pay damages if he was negligent or acted wrongfully, but the payment of heavy legal charges, in addition to enduring anxiety and wasting time, through having to defend himself against undeserved attack, or such a ridiculous accusation as that brought against Sir Maurice Craig.

Impotence Quoad Hanc.

The bringing in of judges not usually employed in the Divorce Court to relieve the congestion of matrimonial causes awaiting trial has had as one of its results the delivery of a weighty judgment by the Lord Chancellor in a case of a very important class from the point of view of the medical profession. After nearly 10 years of married life, Mrs. Miriam Colman or Hankey withdrew from cohabitation with her husband, and instituted a suit for a decree of nullity of marriage on the ground that there had been no consummation of the marriage and that he was incapable of consummating it. After a prolonged hearing, and after evidence had been given by the parties, by the wife's mother, and by medical men who had examined one or other of the parties, Lord Birkenhead delivered a reserved judgment in which he reviewed the law and the facts. There was, as he described it, an acute contest of fact, as the respondent not only alleged that sexual intercourse had taken place, but also that he had taken steps at one time with regard to making a will in the belief that his wife was pregnant. It was, however, clear from the evidence on both sides that the relations between the parties were not those of normal young married couples. The war accounted for the delay in the institution of proceedings. Lord Birkenhead in his judgment pointed out that the allegation was not that the respondent was generally impotent but that he was incapable of consummating this particular marriage. Doubts had been entertained as to whether impotence *quoad hanc* (that is to say, with regard to the particular woman in question) entitled a woman to a decree of nullity, but, clearly, before and after the Council of Trent, the Church had admitted, and indeed enjoined, nullity on that ground. Recent authority on the point was, however, scanty and he reviewed the various cases decided in the last century in which it had been discussed, referring to the difficulty arising from the parties being the only witnesses on the most important issues. As to this, and the responsibility attaching to the pronouncing of judgment upon the unsupported testimony of the petitioner, the court was not relieved from weighing the evidence, merely because both parties told different stories, one of which must be untrue. He referred to interviews between the petitioner, the respondent, and the petitioner's mother, as to which divergent evidence had been given, as having at any rate taken place, and as showing that up to a certain time difficulties had attended consummation, such as were consistent with the allegation that it had not taken place. With regard to the medical evidence, which he reviewed at length, as to the physical conditions observable in petitioner and respondent, his lordship described it as consistent with the petitioner's evidence and not with that of the respondent. It thus gave him the necessary guidance. Her story might be true. His story could not be true. His lordship, in conclusion, found that the petitioner's story as to the material facts was true, that the marriage had never been consummated, and that over a period of years the respondent had tried unsuccessfully to consummate it. It followed that he had been always incapable of consummating this particular union with this particular woman. There had been no allegation against her of frigidity, denied access, or physical malformation. There will, we think, be a feeling of doubt among medical men on this judgment.

CONTROL OF VENEREAL DISEASE.

THE RED CROSS REGIONAL CONFERENCE.

THE North European Red Cross Conference which was held at Copenhagen from May 20th to 25th, after considering the general measures adopted by the participating countries for the combating of venereal diseases, came unanimously to the following conclusions :—

1. That the provision, by responsible health authorities, of adequate facilities for diagnosis and treatment on lines which insure that the greatest possible number of infected persons is rendered non-infective is a measure of prime importance to the reduction of venereal diseases. The urgent necessity of commencing treatment at the earliest possible moment should be emphasised. It is suggested that the above facilities should be provided free of cost to the patient where they are otherwise unlikely to be utilised to the fullest extent.

2. That the questions of compulsory notification and of compulsory treatment, being dependent on the experience, resources, and psychology of the people concerned in each country, must be decided by individual nations.

3. That instruction, theoretical and practical, in the recognition of venereal diseases, particularly in their earliest manifestations and in their treatment, should form a part of the curriculum of every medical student, and that satisfaction of a test of proficiency in this subject should be a condition of every medical qualification.

4. That provision should be made, at suitable treatment centres, for such instruction of medical practitioners in the diagnosis and treatment of venereal diseases as will enable them to recognise these disabilities promptly and secure their adequate treatment.

5. That regulation and official toleration of professional prostitution has been found to be medically useless as a check on the spread of venereal diseases and may even prove positively harmful, tending as they do to give official sanction to a vicious traffic.

6. That the provision of "hostels" and rescue homes for the temporary care of girls suffering from venereal disease is a valuable means of preventing the spread of these diseases.

7. That the provision of opportunities for wholesome entertainment and recreation is an important factor in reducing the temptation and exposure to venereal infections.

8. That enlightenment of the general public on lines which are best calculated to minimise exposure to infection and emphasise the necessity of thorough treatment is an essential part of any scheme for the combating of venereal diseases. Instruction should particularly be addressed to parents and teachers in such a form as will enable them to give clear information on the reproduction of life and impress on adolescents the importance of individual responsibility to future generations. In the training of teachers special courses on these subjects should be provided.

The Question of Self-Disinfection.

The Secretary of the National Council for Combating Venereal Diseases, which was officially represented at the Conference, writes to us as follows: "A noteworthy point is the fact that the question of self-disinfection, which has appeared such an important and vexed factor in the campaign in England, provoked very little interest at this Conference of experts. Countries that have adopted self-disinfection as a part of their policy, stated, through their representatives, that it was not considered an all-important factor in the general campaign. This is the view taken by our own Ministry of Health according to the leaflet which they issued recently defining their policy. In Germany, where the self-disinfection policy has been pursued in a particularly vigorous manner, the results do not appear to be satisfactory, as venereal disease is spreading amongst the youth of the country in an alarming way. One of the German delegates quoted the following figures for his clinic in a large German industrial town, which has energetically pushed a campaign of self-disinfection for five years.

1919 ..	14 boys ..	60 girls	infected between the ages of 14 and 18 years
1920 ..	105 " ..	116 "	" "
1921 .. (first three months only).	33 " ..	61 "	" "

In Berlin the annual number of fresh infections was estimated by the other German medical delegate at 5,000.

State-Controlled Prostitution.

From the same source we learn that the unanimous opinion of the medical experts assembled at the Conference disposed of the fallacy that officially regulated prostitution is desirable for the purpose of reducing disease. Countries which have these so-called controlled establishments have analysed the results of this system since the publication of Flexner's "Prostitution in Europe." Not only is it proved that this system is medically useless as a check on the spread of venereal disease, but it is positively harmful as it gives official sanction to a vicious traffic. The provision of hostels and rescue homes for women and girls, and opportunities for entertainment and recreation, together with a general campaign tending to raise the standard of public morals, are the important means by which venereal diseases can be combated.

Disease amongst Seamen.

The campaign, initiated by the National Council for Combating Venereal Diseases at the first meeting of the League of Nations last year, to enable members of the mercantile marine of all countries to receive adequate treatment for venereal disease received active support at the Conference when the interests of seamen were particularly advocated by the British delegates, and the Conference approved of a detailed scheme providing for the free treatment of seafarers of all countries.

EXTENSION OF MEDICAL SERVICES: INITIATION OF A COUNTY SCHEME.

THE scheme for extension of medical services in the county area of Gloucestershire was formally adopted in April of last year and is now being put into effect. Dr. J. Middleton Martin, county medical officer of health and executive medical officer of the scheme, in a pamphlet of 16 pages issued by the County Council at 1s., describes the essential features of the extension, the genesis of which may be of interest to other sanitary authorities.

Provenance of the Gloucestershire Scheme.

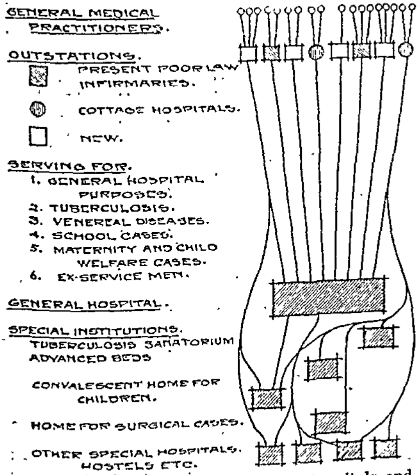
A scheme of out-stations in connexion with general hospitals in the Gloucestershire area was first propounded in a communication made in April, 1918, to the Ministry of Pensions in response to a request for a survey of institutional accommodation. In December, 1918, the Gloucestershire War Disablement Subcommittee passed a resolution in favour of the principle of the scheme, and in the same month a scheme of out-stations in connexion with general hospitals was submitted to the Local Government Board. In January, 1919, a general hospital (Cheltenham) accepted the principle of the scheme, which was about the same time submitted to the Board of Education. In February, 1919, the scheme secured the approval of the Gloucestershire Branch Council of the British Medical Association, and in March the Local Government Board signified approbation of the association of special work of local authorities with out-stations of general hospitals. On May 29th, 1919, the principle of the scheme was approved at a mass meeting of the medical profession in the county, and on the following July 7th it was formally adopted by the County Council. In September, 1919, a grant of £7000 towards capital expenditure was received from the Joint War Committee of the Red Cross. The detailed scheme was formally submitted by the council to the Ministry of Health in October, 1919, and formal approval obtained in April, 1920.

Requirements of a County Area.

The medical needs of a county area are, it is pointed out, much more difficult to meet than those of a large urban centre. Where Bristol has 13,100 persons to the square mile, the county of Gloucestershire has only 268. In a sparsely populated area it is impracticable to establish centres for each class of case; and while there are administrative advantages in working a scheme by whole-time special officers, it is needful to secure the attendance of specialists for examination and treatment of special groups only. Specialist services are required for consultation rather than routine examination. Based on these principles, the Gloucestershire scheme consists in the opening of out-patient departments at 11 cottage hospitals and 41 new out-stations of the general hospitals (somewhat on the lines of existing tuberculosis dispensaries with consulting room, waiting room, and dressing rooms), so that one will be accessible within a radius of about every three miles of the county. At these out-patient treatment of all the special classes of persons, for whom provision has at present been made at the public expense or may be made in the future, will be available. The usual medical attendants will be the local practitioners, and the specialist staff of the general hospitals will attend periodically for consultation and for the examination of cases reserved for them. An ambulance service will be available for general hospital cases, the out-stations being primarily intended for the special groups of cases whose treatment will be such as can be given in an out-patient department.

Utilisation of Existing Machinery.

In the large general hospitals are to be found the most complete equipment for medical and surgical treatment, and the most highly trained medical, surgical, and specialist services; of these there are four in or bordering on the county. There are also dotted about the county 11 cottage hospitals and, distributed over the same area, 240 medical practitioners. In the general hospitals will be the consultant services, and through the agency of the smaller hospitals and the medical practitioners, working closely in coöperation with the general hospitals, complete medical services available for the whole area of the county can be provided. Dr. Martin uses a familiar but convenient diagram to express the inter-relations of these various units.



GENERAL MEDICAL PRACTITIONERS.
OUTSTATIONS.
PRESENT POOR LAW INFIRMARIES.
COTTAGE HOSPITALS.
NEW.
SERVING FOR.
1. GENERAL HOSPITAL PURPOSES.
2. TUBERCULOSIS.
3. VENEREAL DISEASES.
4. SCHOOL CASES.
5. MATERNITY AND CHILD WELFARE CASES.
6. EX-SERVICE MEN.
GENERAL HOSPITAL.
SPECIAL INSTITUTIONS.
TUBERCULOSIS SANATORIUM ADVANCED BEDS
CONVALESCENT HOME FOR CHILDREN.
HOME FOR SURGICAL CASES.
OTHER SPECIAL HOSPITALS. HOSTELS ETC.

Provisional Scheme of Working.

Openings of Out-stations.—At present each of the 12 out-stations is to be open one day weekly for the attendance of the medical officer at a time to be fixed to suit his convenience and that of the neighbourhood; on other days, at times convenient to the neighbourhood, for intermediate treatment (ordered by the medical officer) by the nurse; periodically, for consultations, at times to be arranged between the medical officer and the parent hospital; at convenient times as a maternity and child welfare centre; at other times as may be arranged by the Board of Management for the convenience of the medical officer in seeing general hospital cases or other groups of patients, or for dental treatment, &c.

Persons eligible for Treatment.—The following classes are eligible for treatment under the scheme: (*a*) school children referred from the school by the medical inspector, the head teacher or the nurse, after reference to their usual medical attendants, who will either provide treatment or advise attendance at an out-station; (*b*) persons with symptoms of, or suspected to be suffering from, tuberculosis and contacts; (*c*) persons liable to be suffering from venereal diseases; (*d*) ex-Service men referred by pensions committees; (*e*) mothers and infants under the maternity and child welfare scheme; (*f*) other groups of patients by agreement between the medical officer and the board of management, on the recommendation of the medical advisory committee. Patients in groups (*a*), (*b*), (*c*), and (*d*) will attend at the times of the regular openings; those in group (*e*) when the out-station is opened as the maternity and child welfare centre, and other groups as arranged in the future.

Duties of Medical Officers.—The medical officer will examine all new cases and either treat them himself or give instructions to the nurse for their treatment; by arrangement with the hospital he will reserve groups for consultation with the special officer; he will keep such simple notes of each case as may be necessary to preserve the records of the various patients.

Duties of Nurse.—The nurse will attend at the out-station with, and assist, the medical officer; she will give such intermediate treatment as he may prescribe; she will keep the register of attendances; and ensure that the out-station is kept in proper order.

Preliminary List of Out-stations.

The out-stations which are or soon will be open for intermediate treatment and for consultations are as follows:—

Bristol Hospital Area.—Almondsbury Memorial Hospital (Monday), Chipping Sodbury Cottage Hospital (Friday), Thornbury Out-Station (John Street) (Monday).

Cheltenham General Hospital Area.—Cheltenham General Hospital (Friday), Chipping Campden Out-Station (Back Ends Road) (available shortly), Cirencester Hospital (Wednesday), Tewkesbury Rural Hospital (Tuesday).

Gloucestershire Royal Infirmary Area.—Berkeley Hospital (Wednesday), Cinderford Out-Station (The Institute) (Tuesday), Gloucestershire Royal Infirmary (Wednesday), Tidenham Out-Station (available shortly).

Stroud Area.—Stroud General Hospital (Tuesday).

The medical officers in each case are the local practitioners; where there is more than one, they take duty for six months in turn.

Tuberculosis Dispensaries are open at Cheltenham General Hospital (Wednesday), Cinderford Institute (Tuesday), Cirencester Hospital (by appointment), Gloucester Provident Dispensary (Tuesday and Thursday), Stroud General Hospital (Monday), Thornbury Out-Station (Friday), Warmley District Council Offices (Friday).

Venereal Disease Clinics are available at Bristol General Hospital, Bristol Royal Infirmary, Cheltenham General Hospital, Gloucester Royal Infirmary, Stroud General Hospital: in each case on two or more days of the week.

Dr. W. Arnott Dickson, to whose practical suggestions the scheme owes much, has been appointed its clinical medical officer.

Consultants Attached to the Scheme.

The following is a list of the consultants attached to the scheme, arranged under the general hospitals to which they belong:—

Bristol Hospitals.—Physicians: R. C. Clarke, Cecil Clarke, C. E. K. Herapath. Surgeons: A. W. Adams, H. Chitty, D. Wood, C. A. Moore, A. R. Short. Ophthalmic surgeons: A. E. Iles, E. H. E. Stack. Ear, nose, and throat: J. P. I. Harty, A. J. M. Wright. Gynæcologists: W. C. Swayne, R. S. S. Statham.

Cheltenham General Hospital.—Physicians: J. P. Johns, S. M. Hebblethwaite. Surgeons: J. Howell, J. R. Collins, J. C. R. Braine-Hartnell, T. Holmes. Ophthalmic surgeon (ear, nose, and throat): N. H. Pike. Maternity and child welfare: H. F. Powell. Radiologist: H. M. Meyrick-Jones. Dentist: G. A. Peake.

Gloucestershire Royal Infirmary.—Physicians: W. W. Grosvenor, D. E. Finlay, H. Cairns Terry. Surgeons: W. Washbourn, C. V. Knight, A. Alcock, R. L. Haines. Ophthalmic surgeon: W. Niccol. Ear, nose, and throat: H. Smurthwaite. Radiologist: J. C. Webb.

Stroud General Hospital.—Surgeons: A. Barnes Davies, A. W. Waller, C. L. Coode, J. C. Marklove.

The estimated cost of maintenance for the year 1921–22 is below £5000. The Ministry of Pensions pays the whole cost for ex-Service men, and the Ministry of Health will make grants of 75 per cent. for venereal diseases and 50 per cent. for other services.

THE CLINICAL UNIT IN OBSTETRICS AND GYNÆCOLOGY AT THE ROYAL FREE HOSPITAL.

THE staff of this unit at the Royal Free Hospital, which is at present the only teaching hospital which has a clinical unit in these subjects, is as follows, all the officers being whole-time:—Director: Prof. A. Louise McIlroy; Senior Assistant: Dr. Gertrude Dearnley; Second Assistant: Dr. Charlotte Houlton; Clinical Pathologist and Registrar: Dr. Dorothea Taylor; Resident Obstetric Officers, three. The beds in the unit number 63, of which 12 obstetrical and 25 gynæcological are in the Royal Free Hospital, and 26 in the Marlborough Maternity Block in Endsleigh-street; of the last a few are allocated to private paying patients. Similarly, a certain number of beds are reserved at the Royal Free Hospital in the gynæcological department for paying patients who cannot afford a nursing home. This does not involve any loss of beds for teaching purposes, since practically all patients pay varying amounts, and all enter the hospital on the understanding that students have access to the wards and may examine patients. Students are not allowed to make vaginal examinations in the wards, but only in a special examination room under the direct supervision of the director or an assistant. *One student only examines any case.* This applies to all patients, paying or non-paying, and to obstetric as well as gynæcological cases.

Clinical Work.—All students serve as clinical clerks in the obstetrical department of the unit for three months. A certain number of students are appointed as gynæcological clerks for three months under the unit, the remainder of the students serving as gynæcological clerks for another firm, the selection of students being made by a committee consisting of the dean, the warden of the Medical School, the director of the unit, and a senior student. These clerks take the records of the cases and examine the patients under the direct supervision of one of the assistants in small rooms fitted up for the purpose. They also conduct the cases of normal labour under the supervision of the resident obstetric officers. There is a district attached to the hospital where the students attend maternity cases under the supervision of the resident district officer. Students engaged in obstetrics are on duty for 12 hours either night or day. There is therefore no necessity to have special quarters for them for sleeping, but rest quarters are provided, and meals, both for night and day students. Antenatal clinics are held twice weekly for out-patients at the Royal Free Hospital and at Endsleigh-street. Gynæcological operations are performed by the director and her assistants with the help of a theatre nursing staff, working together as a team. Students assist at minor gynæcological operations. Gynæcological out-patients are seen on Saturday mornings at the Royal Free Hospital. Cases specially referred to the director are seen in the out-patients department on Wednesday and Saturday mornings at 10 o'clock. The case records are kept on the general index system instituted by the hospital and are stored centrally, a précis of the case-sheet being kept in the unit for reference when required. The clinical pathologist undertakes the treatment of cases of sepsis occurring in the wards of the unit in order to minimise the risk of carrying infection to other patients, and to free the director and her assistants from contact with septic cases. These cases are isolated in a special department and are not examined by students, who are however, allowed to see the treatment carried out. Cases in the puerperium who have a temperature of 100° F. for more than 24 hours are isolated and treated as septic.

A course of preparatory lectures in obstetrics and gynæcology for junior students is given twice a week by the director. The clinical clerks receive instruction on every case in the unit, and in the out-patients department. The final year students have a tutorial class daily, and a demonstration of operative obstetrics once a week. Special courses of lectures and demonstrations will be given in the winter term for students, and classes for post-graduates will also be held. A course of lectures on the Physiology and Psychology of Reproduction will be held by the director for post-graduates and senior students once a week, beginning in October, 1921.

Pathology.—There is a laboratory attached to the unit for the use of the medical staff for purposes of research; the main routine pathological work is done in the general pathological department. Special demonstrations in gynæcological pathology are given by the director of the pathological department of the hospital and by the clinical pathologist of the unit.

Public Health Services.

LONDON COUNTY COUNCIL ESTIMATES.

THE London County Council has passed a series of estimates totalling £645,711 in respect of the public health services of the metropolis. From the details given below it will be seen that by far the heaviest individual items were those for treatment of tuberculosis (£349,000), and diagnosis and treatment of venereal diseases (£115,100). The full details are as follows:—

	£
Public vaccinators	2,500
Sanitary officers	82,427
Registrars of births and deaths ..	509
Poor-law medical expenses	85,000
Treatment of tuberculosis (residential)	331,500
,, ,, (dispensary)	17,500
Diagnosis and treatment of venereal diseases	115,100
Milk-supply (tuberculosis)	2,965
Infant life protection	6,540
Precautionary measures against spread of epidemic diseases	20
Lying-in homes	60
Public health administration	100
Special county public health administration, including enforcement of Dairies, Cowsheds, and Milkshops Orders	665
Common lodging-houses and seamen's lodging houses	750
Miscellaneous expenses	75

SCHOOL MEDICAL INSPECTION.

Reading.

The first report issued since October, 1920, when the school work was undertaken by whole-time instead of part-time officers, deals mostly with the work under the part-time system. Dr. H. J. Milligan now combines the work of the public health and school medical departments with the help of two whole-time assistant school medical officers, and of Dr. J. A. P. Price, who still gives part of his time to the work. There are 14,752 children in attendance, and of these 4290 underwent routine medical inspection; 64, or 1·5 per cent., were found to be suffering from malnutrition; 139, or 3·2 per cent., from defective vision; and 158, or 3·7 per cent., from enlarged tonsils or adenoids. 19 children suffered from defective hearing, and 25 from otitis media. 154, or 3·6 per cent., were found to be unclean either in head or body. 238 children attended the ophthalmic clinic throughout the year, and for 107 of these Dr. Price prescribed glasses; the Education Authority provided glasses for 144, a considerable proportion of the expense being recovered from the parents. Playground classes are held in practically all the schools, while two schools arrange school journeys of a fortnight's duration. The open-air school is solely for children who suffer from tuberculosis in one form or another, but the cases are mainly pulmonary. There is an interesting table showing the after careers of children who have attended the physically defective, the open-air, and the mentally defective schools. Of the 77 girls attending the continuation school 7 were unclean, 1 suffered from spinal curvature, and 5 from flat foot.

Eastbourne.

In Eastbourne the public health school and infant welfare work are well coördinated. The school medical officers are also public health officers, and three out of the four nurses employed devote part of their time to infant welfare work. In addition, there are eight part-time medical officers. The adaptation into an open-air school of six army huts, with accommodation for 50 children, surrounded by a large area of open ground, is the outstanding feature of the year, and was foreshadowed in Dr. W. G. Willoughby's previous report. The results have already been so good that Dr. Willoughby suggests an extension to the school. Dinner is provided for all the children in attendance, and certain of them have milk in the morning. This school is a valuable asset to the tuberculosis and malnutrition clinic, where 92 children made 263 attendances throughout the year. The results of medical inspection in the continuation schools are interesting. The percentage of defects is high (41 per cent.), the number requiring treatment and observation being about equal. Dr. Willoughby writes: "I attribute the large number of deformities, many of them slight but still interfering with the perfect health of the individual, to the lack of systematic physical training in the elementary schools curriculum. It is obvious, I think, that the children do not get sufficient physical exercises. If they did there could not have been the number of misshapen spines and flat feet." Dr. T. Turner reports that having examined every boy in the secondary school, and four months' later having re-examined the cases noted for observation, he finds the general physique of the school good. He was struck by the almost complete absence of spinal curvature. Among the boys of the continuation school he finds the physique poor, especially among errand boys, and a large number of the latter suffered from flat foot. He attributes these physical defects to the fact that these boys attend school only twice a week, and therefore get no systematic training and spend little time in organised games.

Dewsbury.

2376 children underwent routine examination during 1920. 151 of these were found to be suffering from defective vision, 42 from defective teeth, 51 from defective conditions of nose and throat, 1 from speech defect, and 3 from pulmonary tuberculosis. Dr. Oscar Holden reports that if pulmonary tuberculosis looms largely in the returns of a school medical officer doing *routine* school inspections one must perforce believe that officer to have a bias, and *not* necessarily believe that tuberculosis is rife in any particular school. The report contains the interesting statement that the condition of teeth in the industrial towns of Yorkshire and Lancashire is considerably inferior to that seen in the agricultural classes of the south. "Whether the softness of the water, or the general hygienic surroundings, or the character of the food plays the most important part it is very difficult to say. An investigation carried out by me in regard to the dietaries of children with sound and unsound teeth revealed no difference. Bad teeth seem to be a family characteristic, an inherent tendency rather than a circumstance of environment." Glasses were prescribed for 110 children and obtained by 98. Provision is being made for carrying out remedial exercises at the new clinic. This will be undertaken by the organiser of physical culture under the direction of the school medical officer.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Warning to Would-be Medical Students.

STUDENTS who have just completed their middle school course, having passed the "maturity" examinations, are being circularised with an appeal not to enter upon the study of medicine. The chief reason offered is the unfavourable financial condition of an exceedingly large percentage of physicians, consequent on the loss of two-thirds of the territory of Hungary by the Trianon peace treaty. Formerly patients poured into Budapest in vast numbers from the provinces. From every corner of the land doctors sent their patients for special treatment and consultation. But now patients from the occupied territories are prevented from coming to Budapest by technical obstacles. First of all there is the compulsory passport system; to procure a passport and necessary *visa* takes much time and expense. In fact a journey to Budapest from the occupied territories must be regarded as a luxury; for instance, the journey from Oradea Mare (late Nagyvarad), altogether 200 kilometres (about 130 miles) from Budapest, which took four hours by fast train before the war, with a service of seven to eight trains a day, now takes 24 hours. From Oradea Mare one has to go either by carriage or by automobile to Bors, the Roumanian custom station; thence by foot to Kerentes; thence by carriage to the Hungarian boundary; and thence by railway to Budapest. This roundabout journey has to be made because the direct railway line cannot be used for lack of interchange of railway engines and cars. The facts commented on in the circular are: (1) the surplus of medical men beyond the demand; (2) the abrogation of the laws against practice by the incompetent; (3) the legislation for the various sick clubs. The number of physicians in Budapest alone amounts to 2000, while in 1913 the number was slightly over 1000. Thus the number has more than doubled in eight years, and the prospects are that it will grow still larger. A further reason for avoiding the study of medicine given by the circular letter is the addition to the course of a "practical year," whereby the expenses of preparation for the profession, already very costly, are still further increased.

A Case of Boric Acid Poisoning.

The popular fallacy that boric acid is innocuous to the system is contradicted in a case which occurred two weeks ago in a Hungarian village. The patient, a man aged 23, suffered from bilateral inguinal adenitis, which had been incised, by a surgeon in the next town, and the patient went home with instructions how to dress his wounds. However, the patient, who had been in the sanitary service during the war, remembered that boric acid powder was administered in cases of suppurative mastoiditis. This recollection induced him to pack the cavities of his buboes with boric acid powder. He used for this purpose about 150 g. Soon afterwards the man developed the typical signs of boric acid poisoning, profuse vomiting, a papular rash over the face, neck, and chest, and a weak irregular pulse. The onset was rapid and the fatal issue came on within four days. There was also delirium and slight rise of temperature. Post-mortem examination showed congestion of the liver, spleen, and gastro-intestinal tract, and cloudy swelling and granular degeneration of the liver and kidney cells. There were also subpericardial hæmorrhages, together with discoloration and maceration of the tissues about the cavity in which the boric acid was placed. These findings limit the cause of death to a toxæmia resulting either from the abscess in the groin, or from the medicinal agent employed, as other recognisable causes were not present. Its recognblance to other cases previously reported (the last one described by Dr. C. I. Best in America), together with the demonstrated over-use of the drug, was sufficient for the diagnosis. The clinical features and the lack of success in cultivating pathogenic bacteria from the blood eliminate septicæmia, which is the condition most likely to be simulated in such a case.

Serum Treatment of Articular Rheumatism.

Dr. Radvanyi (Transylvania) states that better results in the treatment of acute and chronic articular rheumatism have been obtained from the use of antistreptococcus serum than from any other medicine. Chronic cases, if not cured, are materially improved, and in acute cases an endocarditis will heal more rapidly. As proof of the latter fact a case is cited which presented well-marked increase in cardiac dullness with presystolic murmurs at the apex during an acute attack; two years after treatment there were no longer any definite signs of endocarditis. Since the serum may render acute a chronic inflammatory process, Dr. Radvanyi says it should be used with caution in pericarditis, marked pleurisy, or advanced mitral stenosis. In acute cases single doses of 5 c.cm. should be employed (strength of the serum according to the severity of the symptoms), while if chronic, several periods of treatment are necessary. The other measures employed for rheumatism are also in place, but salicylates need not be given while serum treatment is being employed.

May 28th.

Obituary.

JOHN MATTHEW FORTESCUE-BRICKDALE,

M.D., B.CH. OXON., M.R.C.P. LOND.,

PHYSICIAN TO CLIFTON COLLEGE AND TO THE BRISTOL ROYAL INFIRMARY.

WE briefly recorded last week the death at an early age of Dr. J. M. Fortescue-Brickdale, in whom medicine as an art and medicine as a science were well blended. Born in London in 1869, son of the late Mr. Matthew Inglett Fortescue-Brickdale, conveyancing counsel to the Court of Chancery, he was educated at Dulwich College—where his literary bent already found expression in a school paper of a satirical character entitled "The Culex"—and at Christ Church, Oxford, receiving his medical education at Guy's Hospital. Of this period of his life one of his friends relates:—

> J. M. Fortescue-Brickdale came up to Guy's from Oxford in 1892, and for seven years was one of the most popular men in the hospital. His personality was effective; his smooth black hair, short-sighted eyes, and precise. rather drawling speech, marked him at once as a man out of the common rut of his fellows. Of wide education and interests, musical, artistic, and Athenian in his pursuit of all new things, whether in medicine or the humanities, he was an amusing companion and a keen and critical worker. He took a prominent part in the social life of the hospital, and was a brilliant and frequent speaker at the hospital debating society, where he would champion any cause which, by verbal sophistry, could be made to appear unpleasing to the Philistine. Brickdale was one of that small group who founded a short-lived but famous publication "The Guyoscope," which in its day satirized the staff and school of Guys, and contained witty articles on men and medicine, highly appreciated by those who knew the sly allusions. At any reunion of Guy's men it was always a scramble to get near "Forty" when he made one of his rare appearances, for age and work did not diminish his charm or lessen the affection with which he was regarded by his old hospital contemporaries.

Graduating M.B., B.Ch. at Oxford in 1898, he became clinical assistant, and afterwards house physician, at Guy's Hospital. leading on to his selection as school doctor at Uppingham. Upon resigning this appointment in 1903 he settled in Clifton. Soon after his arrival there he became assistant physician to the Royal Hospital for Women and Children. Later his interest in pharmacology, particularly in relation to organic compounds, obtained for him the distinction of being madt lecturer in pharmacology at Oxford while residene in Bristol, where he directed the public health laboratory attached to University College, and demonstrated physiology.

In 1908, Dr. Fortescue-Brickdale was elected assistant physician to the Bristol Royal Infirmary, a further link in the connexion between his family and the infirmary. As long ago as 1766 Matthew Brickdale, by virtue of his uncle's legacy of £200, obtained for himself and his heirs the "power and privelage" of perpetual subscribers. In 1840 Dr. Fortescue-Brickdale's grandfather successfully claimed this right, and in 1867 his father's name was entered on the list of life trustees. A family interest in the institution which had thus existed for more than a century and a half was thus cemented when Dr. Fortescue-Brickdale became a member of the honorary staff. His devotion to the Royal Infirmary amply upheld the tradition of his forbears; for a number of years he was lecturer and examiner to the nursing staff, and his experience in this capacity bore good fruit in the last book he published before his death, "A Text-book of Pharmacology and Medical Nursing for Nurses."

Fortescue-Brickdale served in the war as a Captain, R.A.M.C. (T.), first at the 2nd Southern General Hospital in Bristol and later for about two years in France, where he was for some time in medical charge at the Michelham Home at Cap Martin. Whilst in France he contracted a severe illness, the effects of which, it is believed, shortened his life. On his return to home service he had charge of a special centre for chest wound cases, on which he published a report in the *Quarterly Journal of Medicine* in 1918. Apart from this and some work on children's diseases, his writings were chiefly devoted to the chemistry and therapeutic actions of drugs. Collaborating first with Prof. Francis in a "Chemical Basis of Pharmacology," he brought out in 1910 a "Practical Guide to Newer Remedies," and later (jointly with Mr. H. G. Armstrong) a book on "Infectious Diseases in Schools." He contributed a number of therapeutic articles to the "Practitioner's Encyclopædia of Medical Treatment."

For the past seven or eight years Dr. Fortescue-Brickdale acted as physicain to Clifton College, and found there most congenial work. He watched over the health of several hundreds of boarders with the most particular care; again and again, by taking suitable measures at the first beginning of an illness, he was able to avert serious consequences. His surgical colleague on the staff writes of him as very sane in his diagnosis and treatment. "He made lots of friends and no enemies, although he was one of those men who have not the gift of advertisement, and few knew how good he really was. During the weary months of his last illness the true qualities of the man shone out nobly; none of those about him are likely soon to forget his uncomplaining patience and Christian courage."

Fortescue-Brickdale was a man of many interests, widely read and endowed with considerable literary gifts. He was an active member of the editorial committee of the *Bristol Medico-Chirurgical Journal*, where his colleagues found his eclectic taste of singular value. There are few charming little bits of verse from his pen. He loved music and played the violin well for an amateur, regularly taking part at Oxford in the quartets at the medical reunions held in the rooms of the late Dr. Mee. As a colleague he won universal esteem, total absence of self-seeking endearing him to all with whom he worked or came in contact. One note of appreciation which we have received ends: "He was an upright, staunch man, whose untimely death leaves his colleagues with a sense of intimate and personal loss."

Dr. Fortescue-Brickdale leaves a widow and two sons.

THE SALE OF DISINFECTANTS.

To the Editor of THE LANCET.

SIR,—May I supplement the most useful article on the subject of the sale of disinfectants in your issue of May 14th by a fact which may not be known to many of your readers? Under the Poisons and Pharmacy Act, 1908, all of those disinfectants which contain over 3 per cent. of carbolic acid and its homologues have to be labelled "poisonous," and so may not be sold except by chemists. But comparatively useless material of feeble disinfectant value, with not more than 3 per cent. of carbolic acid and its homologues, need not be so labelled, and may be sold at oil and grocery shops and stores. The Act therefore tends to favour the sale of these low-class disinfectants, for the public buys more disinfecting material from oil and grocery shops and stores than from chemists. It is not generally realised that when such disinfectants are bought at oil shops, &c., the purchase under present conditions must be of a low-grade article, which, if it disinfects at all in the circumstances of its use, is an uneconomical purchase having regard to the large amount which must be employed.

If these handicapping circumstances are not to operate against the sale of the most efficient (and cheapest) disinfectants, the above facts must be kept in view by those who advise the public in the use of these articles. The resolution referred to by the writer of the article, as proposed by me and carried at the Birmingham Congress of the Royal Sanitary Institute last year, was designed to protect the public against the sale of useless material and misrepresentation, so far as disinfectants are concerned. The resolution has been endorsed by a majority of all county borough councils—to whose verdict it has been submitted; and not a single council has had anything to say in disapproval.

I am, Sir, yours faithfully,

HENRY KENWOOD.

University College, London, June 11th, 1921.

CHRÓNIC TROPICAL ULCERATION IN EUROPEANS.

To the Editor of THE LANCET.

SIR,—In certain tropical areas a chronic ulceration of the lower limbs has been observed which gives rise to considerable trouble in treatment, and to a somewhat important point medico-legally. My experience of this trouble is confined to two areas: Cocos, in the Indian Ocean, and Perim, in the Red Sea. In both these places the lesion is exactly similar in onset, course, and result, and is known locally as Cocos or Perim sore. The ulceration is confined to the lower limbs, and commences either as some small skin abrasion or by a small vesicle. The course is rapid, the ulceration spreads quickly, the surrounding skin becomes inflamed, and a dark crust forms over the necrosed skin. On removal of this crust a deep punched-out ulcer is found, the bottom of clean pink granulations with piled up skin surrounding it. This is very sluggish in healing and is liable to break down on the slightest provocation. On healing there is left a dark-coloured cicatrix, very lasting, that is almost identical with a syphilitic scar. No pyogenic organisms are found, and self-inoculation was negative in result. Both Castellani and Stitt seem to look on these ulcerations as mostly syphilitic in origin; but this seems to me too great a generalisation. In some marked cases this origin is practically impossible; in others, extremely improbable. Rather does the lesion seem to come under the "deficiency" group. In support of this view, one deduces certain facts. An identical ulcer does not appear in the natives in these regions. A free supply of fresh vegetables and fish at Cocos reduced the trouble by at least 50 per cent. This ulceration in Europeans never occurs in areas except where the ordinary diet is unavoidably restricted. It is quite possible that, given the bodily condition for the development of the complaint, the local structure and conditions may aggravate it, as, in both these areas (coral and coral c. larva) undoubtedly sea-bathing is an intense irritant. In both these places a similar small but very painful ulceration is often set up in the mucous membrane of the inner ear after contact with sea-water.

The most effectual treatment of the complaint seems to be the packing of the ulcer with lot. rubra, with occasional application of hyd. perox. and ung. protargol. 7 per cent. The medico-legal point is that, from a life insurance point of view, the peculiar and persistent coppery-stained cicatrix is, by an unwarned observer, naturally taken for syphilitic. I am personally aware of a case which was rejected as an ordinary risk, and considerable family unpleasantness caused, in a young man whom I myself treated for these sores, and who was, I am convinced, never infected syphilitically. It would be interesting to hear if any other observers in similar area can be induced to give their views.

I am, Sir, yours faithfully,

B. E. EDGE,

May 25th, 1921. Port Medical Officer, Perim.

THE TREATMENT OF DIABETES.

To the Editor of THE LANCET.

SIR,—In your issue of April 23rd there is a review on my book on "Diabetes." I cannot agree with the reviewer regarding the statement that sodium nitro-prusside is a better test for aceto-acetic acid than for acetone. It may be unfortunate that we may get a positive reaction with sodium nitro-prusside where diacetic acid or acetone is present, but there are thousands of cases where we get a positive reaction for acetone and find no diacetic acid, either with Gebhardt test or ferric chloride, or whatever other test we may employ. Again, out of about one thousand cases I have come across three to four that gave a positive reaction for diacetic acid and no reaction with sodium nitro-prusside for acetone.

I am, Sir, yours faithfully,

New York, May 24th, 1921. PH. HOROWITZ, M.D.

THE FEDERATION OF MEDICAL AND ALLIED SOCIETIES.

To the Editor of THE LANCET.

SIR,—In your issue of June 11th the General Secretary of this Federation draws attention to the fact that at their late dinner what he terms "the right hand of fellowship" was held out to the British Medical Association; and he adds, with regard to these two organisations, that "one is primarily concerned with the interests of the patients, and the other with those of the doctor." So far as my knowledge goes, the British Medical Association has repeatedly stated that the interests of the patients and the doctors are one, and that in safeguarding one it is acting similarly to the other. It would not admit any such division of interests as possible either in its central or local organisation; no more than it would in the bedside association of the two concerned. May one venture to know why it has become necessary now to champion the patients' interests by forming a federation; and also how and to what extent these patients are directly represented on the councils of this new body? The Association stated in 1910 that, if loyally supported by the medical profession, it is in a position to carry successfully into effect all the aims and objects of the Federation. It is a little difficult to appreciate how a group of societies, formed for the advance of scientific subjects alone, can be expected to become suddenly capable of handling successfully medico-political questions, whether such questions relate to the doctor or patient or both. Would it not be far better for doctors to support on the one hand the Royal Society of Medicine for the science attainment, and the British Medical Association for the medico-political aspirations, rather than to butt in with a new and inexperienced conglomeration?

I am, Sir, yours faithfully,

Hove, June 12th, 1921. E. ROWLAND FOTHERGILL.

*** We publish Dr. Fothergill's letter with pleasure, but the societies allied to the Federation cannot be described as "formed for the advance of scientific subjects alone," and this fact interferes with his main argument.—ED. L.

THE DANGER OF ATHLETICS FOR GIRLS.

To the Editor of THE LANCET.

SIR,—I have been much interested in the recent correspondence, both in the daily press and in THE LANCET, on the subject of athletics for women. During the last five years I have had the opportunity of examining all the students at one of the largest physical training colleges for women, both on their entrance into the college and at the end of each term's work.

Miss C. Cowdroy, in her letter to THE LANCET of May 14th, makes the following statements with regard to physical experts, that "they frequently suffer from heart trouble . . . or from displacements of some kind. Sometimes the monthly disability stops for long periods." I should like to say that I have never come across a single case of heart strain, or of displacement of an organ. The amenorrhœa which occurs during term time, in about 1·5 per cent. of the students, is never permanent, and has never to my knowledge produced any ill-effect, whereas the cases of dysmenorrhœa (which is very uncommon among this class of girl) have frequently been distinctly benefited.

Miss Cowdroy further states "that the attitude of these women to life is frequently not a normal one, their mentality is not healthy." She also speaks of "the curious influence exerted by some of these women on girls, neurotic girls seeming obsessed by them." That such women do exist is certainly true, but to say that the condition is due to the practice of athletics seems to me to be making a very unfair assumption. The cause so far as it is possible to apprehend it at all is probably a very complex one, connected with the social conditions of the time, the excess of the female population over the male, and in particular to the conditions, of necessity, prevailing in boarding schools and resident colleges, in which numbers of women live together without any male society whatever. It is these circumstances which tend to make the teaching profession, but not any particular branch of it, especially prone to produce this type of woman. My experience with regard to the students at this physical training college has been that they are the most natural and normal girls that could be desired. I have on several occasions in conversation with members of the staff commented on the simplicity of the students and their youthful and healthy outlook, and they have invariably agreed with me. These girls certainly compare very favourably with the ordinary flapper and average college student.

Miss Cowdroy says "their marriages are often childless." Such an observation is, of course, of no value. Owing to the diversity of factors involved it would require years of research and a multiplicity of data before any accurate statement on the effect on the birth-rate of any one particular class of training could be made. Everyone admits that excess in physical training is to be deprecated, especially in the case of growing girls and boys, but I do not think that there is at present any evidence that athletics are practised to excess in girls' schools.

The question which, in my opinion, educationalists ought very seriously to consider is whether the daily school curriculum, particularly for girls of 14 to 17 years of age, is not too strenuous, and whether more time ought not to be allowed for complete relaxation and recreation. The time-table in many schools consists of full morning and afternoon sessions, followed by 2 to 2½ hours home-work. Even when 2 to 3 hours a week are apportioned to gymnastics or games it seems to me that such a curriculum constitutes far too great a strain on the average girl, and that it is not conducive of the best results from a physical, intellectual, or even examination point of view.—I am, Sir, yours faithfully,

MARGARET G. THACKRAH.

New Cavendish-street, W., June 4th, 1921.

THE VALUE OF SANATORIUM TREATMENT.

To the Editor of THE LANCET.

SIR,—In your issue of June 4th Dr. J. M. Johnstone claims that sanatorium treatment holds the premier place in the treatment of tuberculosis and stigmatises as astonishing the conclusions, recently arrived at by a tuberculosis officer, that cases do better in their homes. One wonders whether his experience extends to the treatment of patients of the working classes. When an attempt is made to trace after-histories, dispensary practice shows that the results of sanatorium treatment are disappointing, and the final result in those who have had it is little better than in those who have not. It is a common occurrence for patients to go downhill rapidly six months after discharge from a sanatorium as improved or much improved. This result is not the fault of the sanatorium, but rather of a system which tends to label that institution as the sheet-anchor in the treatment of the disease.

It has been stated frequently that most of the treatment of a working-class patient with tuberculosis must be carried out at his own home, and in my experience some undoubtedly do better in their own homes, and do not need institutional treatment. Give him a short period of educational treatment at a sanatorium by all means, or send him because he believes in the "cure," but he cannot stop sufficiently long to bring about a cure. Modern opinion makes resistance the keynote to the treatment of the disease. Cannot our efforts be concentrated on raising resistance in the home? Better food and adequate rest seem to be most important factors, and the working man is slowly getting both. There are other factors, of course, but I am not convinced that the sanatorium holds the premier place any more than housing does.—I am, Sir, yours faithfully,

F. G. CALEY,
Tuberculosis Officer.

Metropolitan Borough of Wandsworth
Tuberculosis Dispensary,
June 7th, 1921.

DIGITALIS AND THE PERIPHERAL CIRCULATION.

To the Editor of THE LANCET.

SIR,—Your correspondent, Dr. W. J. Grant, whose letter appeared in THE LANCET of June 4th, has not grasped the principles on which the conclusions arrived at in my paper have been based. In order to form a clear conception in regard to the pharmacology of digitalis it is necessary to have a clear idea as to the meaning of systolic, diastolic, and pulse pressure. Obviously, it is the increased pulse pressure which effects an increased volume of flow per unit of time at a time when both systolic and diastolic pressures are lower than normal. The more complete emptying of the veins near the heart which takes place owing to the greater systolic output may also affect the flow of the blood through the peripheral circulation to some extent.

I have already dealt in my paper with the problem of dilatation of capillaries, &c., to which I should like to refer your correspondent. Incidentally, I should like to state that already the old physicians observed an alteration in the character of the pulse after digitalis, doubtless due to the increase in pulse pressure which this drug effects. The observation was made by the simple method of feeling the pulse. Sir James Mackenzie, however, for whom sometimes facts do not exist which cannot be determined by his favoured methods, ridiculed the idea of a "digitalis pulse."

I am, Sir, yours faithfully,
I. HARRIS.
Liverpool, June 10th, 1921.

THE INHERITANCE OF ASTHMA.

To the Editor of THE LANCET.

SIR,—In his lecture on asthma, reported in THE LANCET of May 28th, Dr. A. F. Hurst shows clearly that this disorder is heritable, quoting Hyde Salter's 217 cases in which 39 per cent. were inherited. Before the modern researches as to the pathogenesis of asthma this fact of its inheritance could hardly attract the attention of the Neo-Lamarckian. But now that it is known that there are at least two factors which may operate in producing asthma, toxic idiopathy and an irritable bronchial centre, and that "in half of Walker's cases beginning after the age of 50 the patient was sensitive to a protein with which he came in contact as a result of his work"—for example, bakers, ostlers, coffee-sifters, and chemists—there is strong presumptive evidence afforded of an acquired character being inherited. Mendelians may wish to analyse the transmission of an irritable bronchial centre and a toxic idiopathy by their special laws of genetics, but, even if they find an answer, it would still leave the initial variation in question unexplained, whereas the facts would be strictly in keeping with Neo-Lamarckism. If their Neo-Darwinian opponents cannot refute the facts stated they must allow this instance to the Neo-Lamarckians.

I am, Sir, yours faithfully,
WALTER KIDD.
Cheltenham, June 8th, 1921.

A DEVELOPMENTAL ANOMALY.

To the Editor of THE LANCET.

SIR,—An annotation which appeared in your issue of May 28th dealt with two anatomical freaks, but neither of them was quite such a freak as the normal fœtus of your second note which thickened its ectoderm at the fourth month, and to which a lot of things happened at 13 months.

I am, Sir, yours faithfully,
J. ERNEST FRAZER.
St. Mary's Hospital, W.,
June 7th, 1921.

*** We plead guilty to a slip so obvious that it could hardly mislead the reader. *Month* should, of course, read *millimetre*.—ED. L.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—My name was not mentioned in the *Daily Mail* of June 13th in the article "Do Eyes Radiate Energy?" and I write to state that the information was given to the *Daily Mail* by someone amongst the manufacturers to whom the work had to be shown for the production of instruments. This was without my knowledge and against my wishes. The work is on the eve of announcement in the medical and scientific press, and is to be demonstrated at the Ophthalmological Congress at Oxford on July 7th. I must point out, as the author, I am annoyed at such a breach of confidence.

I am, Sir, yours faithfully,
CHARLES RUSS, M.B., &c.
Beaumont-street, W., June 13th, 1921.

Medical News.

UNIVERSITY OF CAMBRIDGE.—*Third Examination for Medical and Surgical Degrees.*—The Registrary desires to call the attention of the tutors and prælectors of colleges and of the deans of medical schools to the report of the Special Board for Medicine of May 4th, 1921 (*Reporter*, p. 953), recommending important alterations in the times for the sending in of the names of candidates for the third examination for medical and surgical degrees, and for the presenting of certificates for the third examination for medical and surgical degrees. All medical students should be instructed to substitute the words thirty-first for tenth or thirty-one for ten, and thirty-one days for three weeks on pages 11, 17, 35, 36 of the Regulations and Schedules for Medical and Surgical Degrees. The additional fee for late entry is £2.

UNIVERSITY OF OXFORD.—Dr. Ernest Mallam, Magdalen College, has been appointed Litchfield Lecturer in Medicine for two years as from Oct. 5th, 1921.—Dr. Leonard Hill, F.R.S., has been reappointed Examiner in Animal Physiology in the Final Honour School of Natural Science.—The following have been re-elected members of the Board of the Faculty of Medicine: Dr. E. W. Ainley Walker, Fellow of University College; Dr. James H. Thursfield, Trinity College and St. Bartholomew's Hospital; Dr. Claude G. Douglas, Fellow of St. John's College.

Diploma in Public Health.—The following passed in Part I.: H. L. Coulthard, E. ff. Creed, S.-el-D. A. El Daab, A. Hunter, J. B. Kirk, N. B. Laughton, E. Newton, S. G. Overton, A. J. Partridge, E. G. Rawlinson, W. G. Southey, C. J. Todd, M. P. Wilson. The following passed in Part II., and received the diploma: H. L. Coulthard, T. J. Lloyd, G. W. Ronaldson, C. W. Sharpley.

UNIVERSITY OF MANCHESTER.—Mr. D. N. S. Watson, M.Sc., a former student of the University, has been appointed to the Jodrell Chair of Zoology and Comparative Anatomy in the University of London.—The following appointments have been made: Assistant Lecturer in Botany, Mr. Samuel Williams; Demonstrators in Pathology, Dr. P. I. C. Gibson and Dr. A. Haworth: Demonstrators in Anatomy, Dr. Georgina May Duthie and Dr. R. C. Shaw.—The Turner Medical Prizes have been awarded to Mr. G. V. Ashcroft and Miss Margaret Single.

UNIVERSITY OF BRISTOL.—Sir Isambard Owen is resigning his position as Vice-Chancellor of the University of Bristol, a position he has occupied with conspicuous success since the foundation of the University. His resignation is due to the fact that he is approaching the age limit laid down by the Treasury rules. Sir Isambard Owen brought to the new University experience gained at St. George's Hospital, at the University of Wales, and at Armstrong College, Newcastle-on-Tyne, of which he was Principal till he came to Bristol in 1909. Since that time the University has increased steadily, not only in numbers and material assets, but also in the width of its appeal to the surrounding counties, and it is this policy of broadening the basis of interest in its work for which the University is principally indebted to Sir Isambard Owen.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A meeting of the Council was held on June 9th, Sir Anthony Bowlby, the President, in the chair. The Council passed a vote of congratulation to Sir Arthur Keith, Conservator of the Museum, on having received the honour of knighthood.—A report was read from the Court of Examiners respecting candidates found qualified for the Diploma of Fellow, and the diploma was granted to the following 25 candidates (including one woman):—

K. B. Bellwood, Cambridge University and St. Bart.'s Hosp.; E. C. Bowden, London Hosp.; G. N. Brandon, St. Thomas's Hosp.; G. W. Carte, Oxford University and St. Bart.'s Hosp.; H. Core, H. Coyte, and S. G. Dunn, St. Bart.'s Hosp.; J. A. W. Ebden, London and Westminster Hosps.; Satapriya Ghosh, Calcutta and London Hosp.; J. B. Haycraft, Edinburgh University and St. Thomas's Hosp.; S. N. Hayes, Middlesex and London Hosps.; O. S. Hulman, Middlesex Hosp.; J. R. Hunter, Cambridge University and Univ. Coll. Hosp.; C. M. Jones, Westminster and St. Bart.'s Hosps.; G. R. M. Kelly, London and Westminster Hosps.; T. P. Kilner, Manchester University and St. Bart.'s Hosp.; C. Lambrinudi, Cambridge University and Guy's Hosp.; H. M. Livingston, Durham University and St. Mary's Hosp.; R. P. S. Mason, Middlesex Hosp.; R. L. Newell, Manchester; H. C. W. Nuttall, Liverpool University; K. G. Pandalai, Madras University and London Hosp.; R. H. O. B. Robinson, Cambridge University and St. Thomas's Hosp.; F. W. Watkyn-Thomas, Cambridge University and St. Bart.'s Hosp.; and H. W. Wookey, Toronto University.

Mr. James Sherren and Mr. J. Bathe Rawling were elected as members of the Court of Examiners.—The following were elected members of the Board of Examiners in Anatomy and Physiology for the Fellowship for the ensuing year:—Anatomy: Arthur Ralph Thompson, John Ernest Sullivan Frazer, Gordon Gordon-Taylor, and William Frederick Haslam. Physiology: Herbert Willoughby Lyle, Francis Arthur Bainbridge, Arthur Rendle Short, and John Mellanby.—The following were elected examiners under the Examining Board for the ensuing year:—Elementary Biology: Thomas William Shore and James P. Hill, Anatomy: Arthur Thompson, Frederick Gymer Parsons, and David Hepburn. Physiology: George Alfred Buckmaster and Herbert Eldon Roaf. Midwifery: George Frederick Darwall Smith, Cuthbert Lockyer, George Drummond Robinson, and Charles Hubert Roberts. Diploma in Public Health: Sir Frederick William Andrewes and Frederick Norton Kay Menzies. Tropical Medicine and Hygiene: H. B. G. Newham and G. Carmichael Low. Diploma in Ophthalmic Surgery: J. Herbert Parsons, H. Willoughby Lyle, and E. Treacher Collins. Diploma in Psychological Medicine: Sir Frederick Mott.—The following lecturers, professors, and demonstrators were elected for the ensuing year:—Hunterian Professors: Sir Arthur Keith, six lectures on the Comparative Osteology of Human Races; Mr. Harold Burrows, two lectures on the Results and Treatment of Gunshot Wounds of the Blood-vessels; Mr. A. G. Timbrell Fisher, one lecture on the Pathology of Chronic Arthritis with remarks on the Basal Principles of Treatment of Joint Diseases as indicated by Anatomical and Physiological Observations; Mr. C. A. Pannett, one lecture on Hydronephrosis; Mr. A. H. Todd, one lecture on Orthopædic Aspects of Rheumatoid Arthritis: Mr. K. Macfarlane Walker, one lecture on Enlargement of the Prostrate. Arris and Gale lecturers: Mr. V. Zachary Cope, one lecture on the Nerve-supply of the Parietal Peritoneum and Superperitoneal Tissues; Mr. F. W. Edridge-Green, one lecture on New Researches in Colour Vision; Prof. Swale Vincent, one lecture on a Critical Examination of Current Views on Internal Secretion. Erasmus Wilson Lecturer: Prof. S. G. Shattock. Arnott Demonstrator: Sir Arthur Keith. Thomas Vicary Lecturer: Sir Charles A. Ballance.—The Committee recommended that the Primary Fellowship Examinations should be held in June and December, 1922, and until further notice.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.—At the monthly meeting of the Faculty held on June 6th the following were admitted (after examination) as Fellows: Dr. John Hutcheson Fyfe, Dr. Archibald Monteath Laurie, Dr. Thomas Talmage Read, and Dr. James Douglas Wright.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The annual elections at the Royal College of Surgeons took place last week. The President and Vice-President, Mr. Edward Taylor and Sir W. I. de C. Wheeler, hold office without change. The vacancy in the post of honorary secretary left by the death of Sir Charles Cameron has been filled by the election of Sir Lambert Ormsby. There are two new members of Council, Mr. Louis A. Byrne and Mr. Seton Pringle.

CONFERENCE ON INFANT WELFARE.—The second English-speaking Conference on Infant Welfare will be held at the Central Hall, Westminster, London, S.W. (instead of as previously announced), on July 5th, 6th, and 7th, from 10 to 1 and from 2.30 to 4.30 each day. On Tuesday, July 5th, at 10 A.M., the President of the conference, Lord Astor, will deliver the inaugural address, followed by consideration, during the morning and afternoon sessions, of papers on Residential Provision for Mothers and Babies. Sir George Newman will take the chair at these sessions, and papers will be read by Dr. Janet Campbell, Miss E. Walker Finlay, Dr. C. J. Macalister, Mrs. Cyril Smithett, Miss M. E. Broadbent, Dr. H. B. Gladstone, and Miss J. Halford. On Wednesday, July 6th, Dr. Janet Lane-Claypon will preside at the morning, and Mr. Wilfred Buckley at the afternoon session. The subject for discussion will be The Supply of Milk: its Physiological and Economic Aspects, and papers will be read by Mr. Nathan Straus, Prof. Stenhouse Williams, Dr. E. W. Hope, Dr. Harold Waller, and Dr. S. G. Moore. From 5.30 to 6.30 P.M. a special medical session will be held, when a discussion on "Uniformity of Method and Practice in the Conduct of Infant Welfare Centres" will be introduced by Dr. Eric Pritchard. All members of the medical profession are invited to attend this session, and will be admitted free on presentation of visiting card. On Thursday, July 7th, Dr. G. F. Still will preside. A discussion on Inheritance and Environment as Factors in Racial Health will be held, and papers will be read by Dr. Helen MacMurchy, Dr. Frederick Hoffman, Dr. C. W. Saleeby, and Dr. Gordon Ley. From 5.30 to 6.30 P.M. a meeting of the General Council of the Association of Infant Welfare and Maternity Centres will be held. The subject for discussion will be "What are the Most Vital and Essential Forms of Child Welfare Work?" All interested are invited to attend, and will be admitted free. Evening lectures have been arranged as follows: July 5th, 7 to 8 P.M., The Ideal Maternity and Child Welfare Centre, by Mrs. H. B. Irving; 8 to 9 P.M., Common Infections in Mother and Child, by Dr. Eric Pritchard. July 6th, 7 to 8 P.M., The Accessory Factors in Infant Feeding; 8 to 9 P.M., The Syphilitic Mother and her Infant, by Dr. John Adams. July 7th, 7 to 8 P.M., The Psychology of the Mother and her Child, by Dr. Flora Shepherd; 8 to 9 P.M., The Tuberculous Mother and her Infant, by Dr. Geoffrey Marshall. A Child Welfare Exhibition will be open from July 5th to 9th, from 11 A.M. to 9 P.M., in the Central Hall, Westminster, where demonstrations on the care of the baby, including feeding, cookery, toilet, exercise, clothing, sleep, habits, &c., will be given. Child welfare doctors, dentists, and oculists will be in attendance daily to give free consultations and advice on the health of mothers and young children. The inclusive conference fee is £1 1*s.* per member, but tickets for various parts of the conference and for attendance without the right to printed matter issued in connexion therewith, as well as all further particulars, can be obtained from Miss Halford, Secretary, National Association for the Prevention of Infant Mortality, 4 and 5, Tavistock-square, London, W.C. 1.

Dr. William Brown, M.D., D.Sc., Reader in Psychology in the University of London (King's College), has been appointed Wilde Reader in Mental Philosophy in the University of Oxford.

ROYAL SANITARY INSTITUTE.—The inaugural address at the Congress to be held at Folkestone from June 20th to 25th, to which we referred last week, will be given at 5 P.M. on June 20th by Lord Radnor, and a popular lecture, "Vitamins and their Relation to Health," will be given by Prof. Edward Mellanby on June 23rd at 8 P.M. Among the subjects on which discussions are being arranged are: Control of the Developmental and Wasting Diseases; Overfeeding and Wasting in Children: Mentally and Physically Defective Children; Administration of Maternity and Child Welfare Work; Day Continuation Schools and the Teaching of Hygiene and Child Welfare; The Backward Class versus the Special School; Child Welfare Centres and Rickety School Entrants; Dental Clinic and Prevention of Physical Defects; Legislative Reforms needed in the Interest of Child Life; Egg Powders and Invalid Wines; The Relation of Hospitals to Preventive Medicine; The Hospital and the Primary Health Centre in relation to a Health Service; The Gloucestershire Scheme for the Extension of Medical Services; Costs and Results of various Public Health Activities; Tuberculosis; Diphtheria, Spread of Disease by Carriers; Poor-law Relief, its Effect on Public Health; Trained Nurses and Public Health Work; Preservation and Restoration of Breast Milk; Hygiene and Personal Efficiency; Health Teaching of Mother and Child; Common Sense Hygiene in the Home; Industrial Fatigue; Work of Research Board: Industrial Welfare; Miners' Nystagmus; Tuberculin Test in Cattle; Slaughtering of Animals intended for Human Food; Milk, and Supervision of Cowsheds: Meat Inspection and Slaughter-houses; Rats, Prevention and Destruction; Smoke Abatement; Housing and Town Planning; Rural Housing; Communal Hot Water and Heating; Hospital and Sanatoria Construction; Utilisation of Sewage Sludge; Refuse Salvage; Roads—Heavy Motor Traffic and District Roads; Disinfection and Disinfectants. Arrangements for excursions are being made, and a Health Exhibition will be held in the Drill Hall from June 20th to 29th. The officers at the Conferences to be held are as follows:—(1) Representatives of Sanitary Authorities; President: The Mayor of Folkestone; Recording Secretary: Dr. A. Wellesley Harris. (2) Medical Officers of Health; President: Dr. J. Wright Mason; Recording Secretary: Dr. Alfred Greenwood. (3) Engineers and Surveyors; President: Mr. H. Percy Boulnois; Recording Secretary: Mr. Edward Willis. (4) Veterinary Inspectors: President: Major-General Sir L. J. Blenkinsop; Recording Secretary: Mr. J. R. Hayhurst, M.R.C.V.S. (5) Sanitary Inspectors: President: Mr. G. M. Pettit: Recording Secretary: Mr. J. H. Clarke. (6) Health Visitors; President: Miss Gertrude Tuckwell; Recording Secretary: Miss L. M. O'Kell. (7) Rat Officers: President: Dr. Nathan Raw, M.P.; Recording Secretary: Mr. G. L. Moore. Congress tickets, at £1 11*s.* 6*d.* each, can be obtained from the hon. secretaries, Royal Sanitary Institute Congress, Town Clerk's Office, Folkestone. Ladies' tickets (not including copies of the Proceedings) 10*s.* 6*d.* each.

LONDON DERMATOLOGICAL SOCIETY.—The annual general meeting of this Society will be held at 4.30 P.M. on Tuesday, June 21st, at St. John's Hospital, 49, Leicester-square, London, W.C. At 5 P.M., the first annual address on the Progress of Dermatology will be given by Dr. T. M. Legge, H.M. Chief Medical Inspector of Factories on Occupational Dermatoses and the State, Lord Chesterfield presiding.

DONATIONS AND BEQUESTS.—The late Mr. Rutherford John Pye-Smith, Professor of Surgery at Sheffield University, who left estate of the gross value of £9596, bequeathed £1000 to Sheffield University for a Chair in Surgery; £100 to Sheffield Royal Hospital; and £50 each to Broompark Mission, Daisy-walk, Sheffield, the Edinburgh Medical Mission, and the Pye-Smith Scholarship Fund, Walthamstow Hall, Sevenoaks.—St. Thomas's Hospital has received £1000 from the trustees of Smiths Charities and £500 from Lloyds Bank.

INTERNATIONAL UNION AGAINST TUBERCULOSIS.—An International Conference will be held in London on July 26th, 27th, and 28th under the auspices of the National Association for the Prevention of Tuberculosis. The annual conference of the Association will be merged in the meeting. The International Union against Tuberculosis is the lineal continuation of the International Tuberculosis Conference which, up to 1913, assembled annually in one or other of the capitals of Europe or in America. The purpose of the International Union is to achieve an effective combination of the nations of the world against tuberculosis. Its President for the current year is Mr. Léon Bourgeois, President of the French Senate, who will be succeeded on the occasion of the impending Conference in London by Sir Robert Philip. The Conference is open to official delegates from countries within the League of Nations and from the United States of America, and from all authorities interested in the subject. It will be welcomed to London on behalf of the Government by Lord Curzon, and Sir Alfred Mond, the Minister of Health. Addresses will be given at the opening meeting by Mr. Léon Bourgeois and Colonel George Bushnell, United States Army Medical Corps. A discussion on the Modes of Diffusion of Tuberculosis throughout the Races of the World will be opened by Prof. A. Calmette, and the subject will be dealt with under the following headings: (*a*) Frequency of tuberculosis among civilised people: its rarity among savage or nomadic races; (*b*) number of persons infected at different ages of life in crowded centres and in rural areas; (*c*) sources of tuberculous infection—expectoration, discharging tuberculous lesions, milk; (*d*) contagiousness of latent lesions: discharge of bacilli by natural excretory channels (intestine, kidney, mammary gland); (*e*) dissemination of tuberculous infection by apparently healthy T.B. carriers: preventive measures against the spread of infection. A discussion on the Rôle of the Medical Profession in the Prevention of Tuberculosis will be opened by Sir Humphry Rolleston, followed by Sir George Newman. The Lord Mayor of London will give a reception in honour of the Union at the Mansion House on Tuesday, July 26th. Other social functions and visits to institutions of special interest are being arranged. A fee of one guinea per representative will be charged, to include copy of transactions.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The annual provincial meeting of this Society was held on June 11th, at the Institute, Welwyn Garden City, Herts, Dr. F. E. Fremantle, M.P., the President, being in the chair. There was a large attendance of members, who first motored from London to Hatfield House, which was visited by permission of the Marquis of Salisbury. The members then proceeded to Welwyn Garden City, where they were entertained at luncheon by the President of the Society. After luncheon a short address was given by Sir Theodore G. Chambers, chairman of Welwyn Garden City, on the Garden City project. He referred to the interest taken in the scheme by Dr. Fremantle, who is one of the directors of the company and has devoted a great deal of time to it. Sir Theodore Chambers emphasised the distinction between the proposed garden city on the one hand and garden suburbs or villages on the other. The fundamental idea of the scheme was the development, in accordance with a carefully devised plan, of a complete self-contained town, comprising within itself its own industries and having a full civic life. It was too much mixed up in the public mind with suburban development, to which it was the antithesis. Suburban development of large towns involved an excessive amount of transport and other sources of wear-and-tear, while the idea of the satellite town or garden city was a redisposition of population in rural surroundings. There was at present a scandalous amount of overcrowding in towns, and the motive of the new development was to move into the country whole communities, rich and poor, together with their working conditions. Sir Theodore Chambers referred to the enormous difficulties inherent in any attempt to remedy the grave housing and allied evils in existing towns—evils due largely to vested interests. In the Welwyn Garden City development would not be hampered by encumbrances of this kind, because (1) the Garden City Company owned in fee simple the whole of the land, comprising about four square miles (about the size of Luton or Bedford), and (2) the dividend on the capital was definitely limited, so that the whole of the excess profit could be used for development and improvement. The land was acquired 15 months ago, and there were now 150 houses completed. Already there were civic meetings, church services, a restaurant, a club, and facilities for tennis, cricket, croquet, &c. The Herts County Council, whose clerk, Sir Charles Longmore, had been a strong supporter of the garden city idea, both here and at Letchworth, had given great assistance by altering the local boundaries so that the Welwyn City now consisted of a single civil parish in one rural district and one Poor-law union. There would be a liaison between the parish council and the city company, the former electing some of the members of the latter. This would give all the citizens a share in the management of the city. Already sites had been taken for factories which would employ some thousands of hands. The city was situated at the junction of railway lines in four directions, and the Great Northern Railway has decided to constitute it a great railway centre, and to give excellent facilities for sidings, &c. The site was from 300 to 400 feet above the sea-level, and the city would have its own water-supply and sewage disposal. There was no large town within eight or nine miles, so that it would be centrally situated in a large tract of country. In conclusion, Sir Theodore Chambers claimed that the idea of the satellite town offered a direction in which true progress might be made towards the elimination of the evils due to the agglomeration of population in large towns, the effects of which, he said, were well known to his hearers. Prof. H. R. Kenwood (M.O.H., Bedfordshire and Stoke Newington) proposed a vote of thanks to the President for his entertainment, which was passed with acclamation. He referred with regret to the fact that Dr. Fremantle's year of office was drawing to a close and congratulated him on its success. The President briefly replied, and called attention to the pioneer work which had been done by Mr. Ebenezer Howard in the inception and development of the garden city idea and the acquisition of the Welwyn site; and also to the great services rendered by Sir Theodore Chambers. After the business meeting, at which were elected 17 new Members and 115 new Associates, the party proceeded to Bedwell Park, where they were entertained to tea by Mrs. Fremantle.

NATIONAL COUNCIL FOR COMBATING VENEREAL DISEASES.—The sixth annual meeting of the Council will be held in the Morley Hall, Y.W.C.A., 25 and 26, George-street, Hanover-square, London, W. 1, on Tuesday, June 28th, at 4.15 P.M., Lord Gorell in the chair.

Mr. George E. Vincent, Ph.D., LL.D., director of the Rockefeller Foundation, and two of its members, were entertained to dinner by the Government at the Carlton Hotel on June 13th. Mr. Churchill, who presided, welcomed the guests on behalf of the Colonial Office which, he said, would do everything possible to assist the work of the Foundation. The study of tropical diseases was a work of mercy and of urgency. Therein lay a line of defence in which all nations could join hands.

COLLEGE OF NURSING, BIRMINGHAM.—For the ten days ending June 11th a considerable undertaking on behalf of the trained nurses of Birmingham and the three counties adjoining, in the form of a scenic fair in Bingley Hall, met with considerable success. The aim of the promoters was to obtain a sum of £10,000 and £21,000 has so far been received. This sum will be allocated as follows: (1) 80 per cent. to found a club for nurses and to endow scholarships for the nurses of Birmingham and the three counties; (2) 10 per cent. to the College of Nursing; (3) 10 per cent. to the Nation's Fund for Nursing.

GENERAL HOSPITAL, BIRMINGHAM.—On June 10th a presentation was made to Dr. Thomas Wilson on his retirement from the medical staff of the hospital after 28 years' service, of which 10 had been spent as assistant obstetric officer, and 18 as hon. obstetric officer. The Bishop of Birmingham presided over a large meeting of subscribers. At Dr. Wilson's request the sum of money collected is to be devoted towards a fund for the purchase of apparatus for medical research and teaching under the guidance of the medical committee. Mrs. Wilson was presented with a valuable necklace in appreciation of her services to the hospital on the Samaritan Committee and in other ways. Dr. Wilson is recommended to the governors for election to the post of consulting obstetric officer.

Parliamentary Intelligence.

HOUSE OF COMMONS.

Wednesday, June 8th.

Medical Services in the Navy.

The House considered on Report the Navy Estimates for 1921-22.

On a vote of £720,500 for Medical Services, including the cost of medical establishments at home and abroad,

Commander Bellairs said he understood that the representatives of the army and navy were meeting together under the presidency of the Lord President of the Council. He wanted, if possible, the Admiralty to meet the War Office and see whether they could not effect economy by amalgamating the medical arrangements of the army and the navy. To give a concrete example, he found in the case of Hong-Kong that the military hospital there had accommodation for 166 patients, and the maximum number of patients accommodated was 64, showing a surplus accommodation of 102. The minimum number of patients accommodated was 20, or a surplus of 146. Similar figures were shown in connexion with the naval hospital, which had accommodation for 135, a maximum accommodated of 97, and a minimum of 55. The Yokohama Naval Hospital, also on that station, was closed all through the war and right up to 1920, and it had now been reopened. He urged that a great deal might be saved if there was a thoroughgoing inquiry, with the object of preventing overlapping between the two services. There was no difference between the body of a soldier and the body of a seaman so far as medicine was concerned. The House would be shocked if it were to investigate the number of medical men, say, on the China station, and the number of men for whom they had to cater. They had also convalescent barracks at Hong-Kong for the military, and if all these arrangements were considered together he thought they could bring about considerable economies. He suggested that a general stocktaking should be made in regard to the medical arrangements, because he did not believe that the medical service was doing its best in both services to cut down expenditure.

Sir G. Collins said if the army and the navy could combine on hospital accommodation it would, he thought, be of advantage to the patients, and, incidentally, to the advantage of the taxpayer. He should like to ask why the Admiralty had refused to adopt the recommendations of the Select Committee on National Expenditure, and present their accounts to the House of Commons in the modern method. The War Office had accepted that recommendation, and a study of the War Office Estimates revealed the cost of patients in every hospital under the War Office, whereas from a study of the Navy Estimates it was quite impossible to find out if these medical establishments were efficiently managed.

Mr. Amery (Parliamentary Secretary to the Admiralty) said that the suggestion of Commander Bellairs that they might secure economy by amalgamating the naval and military hospital work at certain stations abroad was one that naturally at first sight would appeal to the House, and he would certainly promise to look into it, but, at the same time, Members would realise that the conditions of naval and military service and discipline, and many of the aspects of their organisation, were so different as to make it not altogether an easy thing to carry out that amalgamation, though he could imagine that there might be some stations where a military hospital could provide for a certain limited number of naval patients, and vice versa. With regard to the case of Yokohama, he had not only asked for a close investigation as to the cost of that establishment, but also as to the possibility of getting some military establishment elsewhere to deal with patients who at present went to Yokohama. As regarded the point raised by Sir G. Collins, the Admiralty were still considering the whole of their system of accounting. A committee was sitting on the subject, and he hoped that their deliberations would lead to a considerable simplification of their financial methods and accounts.

The vote was agreed to.

Medical Board's Decision Set Aside.

Viscountess Astor asked the Minister of Pensions whether he was aware that James Stanley Fairbank, late officers' steward, second class, R.N., who was demobilised on Feb. 27th 1919, after having suffered severely from sleeplessness and nervous debility, and who subsequently developed neurasthenia, applied for a disability pension in September, 1920, which was recommended by a medical board in December, 1920, but quashed by the regional committee without any further medical examination: why was the opinion of the local medical board set aside by a body which had made no such personal investigation; and would he undertake that the case should be reconsidered on the basis of the original medical board.—Mr. Macpherson replied: Although the medical board which examined this man when he made a claim to pension more than one and a half years after discharge expressed the opinion that his disability was due to service, the Ministry were unable to accept that view, and pension was accordingly refused. The case has now been heard by the independent Pensions Appeal Tribunal, which has confirmed the finding of the Ministry; and, as decisions of the tribunal are final, I regret that the case cannot be reopened.

Welsh Board of Health.

Mr. Alfred T. Davies asked the Minister of Health whether, in view of the fact that under the National Health Insurance one of the Insurance Commissioners for Wales was a woman, he intended to appoint a woman to the Welsh Board of Health.—Sir A. Mond replied: If a vacancy occurs I shall be prepared to consider the appointment of a woman to the Welsh Board of Health. At present the Board, which consists of salaried administrative officers, is sufficient in number for the work to be done.

Thursday, June 9th.

Grants to University Colleges.

Mr. Ernest Gardner asked the President of the Board of Education whether the University Grants Committee was precluded from allocating financial assistance to university colleges where support was not forthcoming from local sources or whether such assistance is to be proportioned to the amount of the support from local sources without regard to the proved educational value of the work of the institution; its increase, if any, in numbers; its consequential legitimate requirements, and the strength or weakness of the financial resources available from which local support might be afforded.—Sir R. Horne (Chancellor of the Exchequer) replied: Local support is regarded as the primary factor in estimating the claims of the different institutions for additional grant aid, but the University Grants Committee are not precluded from making allowance for the other considerations referred to by the honourable Member in their grant recommendations.

Insurance Benefit in Hospital.

Mr. Robert Young asked the Minister of Pensions whether a discharged soldier temporarily unfit for work, and receiving while in hospital 100 per cent. allowance, was entitled to any benefit under the National Insurance Acts while in hospital.—Mr. Parker (for Sir Alfred Mond) replied: Sickness or disablement benefit is not payable to an insured person while he is an inmate of a hospital or similar institution, but the whole or part of the benefit is paid to his dependents, if any, or may be applied towards meeting any expenses for which the insured person may be liable otherwise than to the hospital, or, with his consent, may be paid to the hospital if it is not maintained out of public funds. So far as the money is not used in any of these ways, it becomes payable to the insured person on leaving the hospital. In the special case where the insured person is a discharged soldier in receipt of 100 per cent. allowance, the rate of sickness (or disablement) benefit is reduced by 7*s.* 6*d.* a week unless he has been employed for 26 (or 104) weeks since discharge from the army.

Closed Wards in the London Hospital.

Mr. Charles Edwards asked the Minister of Health whether his attention had been called to the closing of certain wards and curtailment of the out-patient department of the London Hospital; and whether he proposes to take any steps to provide adequate facilities for medical treatment for the people of East London.—Mr. Parker (Lord of the Treasury) replied: The answer to the first part of the question is in the affirmative. As regards the second part my right honourable friend can make no statement until the Government have had an opportunity of considering the Report of Lord Cave's Committee which is now before them, but he would point out that there is accommodation for emergency cases available in the Whitechapel and other infirmaries in East London.

Training Grants for Nurses.

Mr. Hurd asked the Minister of Labour whether any and, if so, how many of the women under training as nurses had been rejected after trial as being unsuited to the nursing profession; and whether, in any of these cases, his Ministry had refused to accept this decision and was continuing the payment of training grants.—Dr. Macnamara replied: No women have been placed in training for the nursing profession by the Ministry of Labour. A number of women, however, are being trained to become qualified midwives. It is the practice to discontinue training immediately if the trainee is reported by the responsible authorities to be unsuitable. If my honourable friend has any particular case in mind, perhaps he would give me details, in order that I may have inquiry made.

Disabled Men in General Hospitals.

Captain Viscount CURZON asked the Minister of Pensions whether the Ministry could occupy some of the vacant wards in hospitals for the accommodation of disabled men, and so release hut accommodation, such as Ruskin Park, and benefit the hospitals.—Mr. MACPHERSON replied: This hospital was transferred to the Ministry of Pensions by the War Office Authorities. It has been fitted with special orthopædic out-patient arrangements, and special sections for treatment of disabled officers and nurses. It has been found to provide the most convenient and, incidentally, the most economical centre for treating the large body of the disabled in that district.

Bellahouston Hospital.

Mr. NEIL MACLEAN asked the Minister of Pensions whether the inquiry into the administration of Bellahouston hospital was a private one; and whether, in view of the general interest in the matter, he would order the proceedings to be conducted in public.—Mr. MACPHERSON replied: The answer to the first part of the question is in the affirmative, and to the second part in the negative.

FRIDAY, JUNE 10TH.

Coroners (Remuneration) Bill.

The House considered the Coroners (Remuneration) Bill as amended in Standing Committee.

On Clause 1, which deals with the increase of coroners' remuneration, Sir JOHN BAIRD (Under Secretary for Home Affairs) moved to omit Subsection 1. He explained that the amendment was necessary to secure that a revision and not merely an increase of the salaries of coroners took place. Should a decrease be found necessary, it could be made if this amendment was agreed to.—The amendment was carried.

Sir F. BANBURY moved to omit Subsection 2, which defines the duties of the authorities charged with the payment of coroners' salaries. He said he wished to draw the attention of the House to the fact that this Bill had been moved by an honourable Member who was a coroner himself, and would receive benefit from the Bill. Whether or not this was within the strict letter of the Orders of the House he contended it was utterly wrong.—The DEPUTY SPEAKER said this amendment would practically destroy the Bill.

Sir F. BANBURY then moved to substitute the word "may" for "shall" in the subsection.

Sir T. BRAMSDON said he had asked Mr. Speaker about the matter, and he had told him that he was perfectly in order in bringing in the Bill and, according to Erskine May, a Member who represented a class was quite in order in bringing in a Bill and voting upon it. He brought in the measure as Past-President of the Coroners' Society for England and Wales, and therefore he did represent the class of coroners.—Sir F. BANBURY said the honourable Member was not returned to that House by the coroners, but by the electors of his constituency. Surely the people to judge whether coroners should receive increased remuneration were the local authorities and the ratepayers. They all knew how heavy was the burden of the rates, and he asked the House to support him in killing this Bill, which had no business to have been brought in.—Mr. BARTLEY DENNISS said he hoped the Government did not support this Bill. He was astonished that it should be in order for a private Member to bring in a Bill which compelled local authorities to raise the fees of coroners by not less than 50 per cent. The House would lose its self-respect if it passed such a measure. No terms were too strong to condemn the Bill.

Sir T. BRAMSDON said that he assured the House that there was no necessity for heat. The proposals were very just. Coroners for counties were paid by salary which was arranged according to the quinquennial valuation under the Act of 1860. Coroners for boroughs were paid by fees, and being a coroner himself he might say that they were the worst paid body of public servants in the whole Kingdom. Coroners for boroughs were paid £1 6s. 8d. for every inquest which they held. The last increase in the fees took place in 1887. If a coroner did not hold an inquest he was entitled to no fee at all. They held a great number of inquiries and got nothing out of them. Moreover, if an inquest lasted three or four days the coroner only got £1 6s 8d. Coroners and High Court judges were the only officials in the country who had not had an increase in their salary. The Bill was not a permanent, but a temporary one. The view taken by the Home Office was that these salaries should be revised.—Mr. S. ROBERTS said coroners were not overpaid at present, and they had not only to pay out of their fees a very much increased remuneration to their staff, but they had got to pay the cost of stationery and postage and increased rates on their offices, as well as increased cost of petrol or hire of conveyances. He supported the Bill, but he must vote for the amendment to leave it to the local authorities to decide, as he objected to Parliament forcing local authorities to make payments.

Sir J. BAIRD said although coroners were paid by the local authorities they were judicial officials, and to that extent they were connected with the Home Office. They had come to the Department and pointed out that there had been no alteration in their fees since 1887. He did not think that it would be easy to substantiate the view that a payment which was adequate in 1887 was adequate for similar services to-day. Yet the fees could not be increased without the sanction of that House. Though the Government were not able, in view of the Parliamentary situation and the business to be got through, to bring in a Bill dealing with their case, it appeared to them that the coroners had a claim for consideration. If this amendment were not carried he would later move one to provide that any increase in salary which might have been granted should be taken into account in the revision under the Bill. The Government had made it clear that if a private Bill was brought in they would favourably consider it, provided that it was amended in such a way as to meet what they considered necessary conditions. He hoped the House would hesitate before refusing a reasonable opportunity for having these salaries revised.—On a division Sir F. BANBURY's amendment to make the Bill permissive was carried by 74 votes to 49.

On the motion of Sir F. BANBURY it was agreed to leave out in Subsection 2 the words: "and if the authority and the coroner fail to agree as to the amount at which the salary or fees should be fixed the Secretary of State shall, on the application of the authority or the coroner, determine the amount, having regard to the increase and other circumstances aforesaid."

Mr. BARTLEY DENNISS moved to leave out from Subsection 2 the words: "Provided that, as respects fees, the amount thereof shall in every case be revised so as to be increased by not less than 50 per centum." The amendment was agreed to.

On the motion for the third reading of the Bill,

Mr. G. BARKER said he agreed that the principle of the Bill was in accordance with equity and justice, but if the House was to legislate it should do so righteously and equitably for all the people of the country. That which was proposed to be given to the coroners was to be taken away from all the workers in this country. The Bill was a piece of downright class legislation.

The Bill was read a third time and passed.

Sick Pay and Light Work.

Mr. THOMAS DAVIES asked the Minister of Health under what Act of Parliament the Ministry of Health had altered the words of the National Health Insurance Act, incapable of work to mean incapable of heavy work, which was the only interpretation that could be given to Model Rule 12 (1) (c) of Model Rules, a 1919 edition, which interpreted incapable of work to mean that a member in receipt of sick pay might do light work; and what was the Ministry's definition of light work.—Sir A. MOND replied: The rule referred to by the honourable Member does not modify in any way the statutory requirement that in order to be qualified for sickness or disablement benefit an insured person must be incapable of work. Under Section 11 (2) of the National Insurance Act, 1911, every approved society is required to have a rule as to the behaviour of members while incapable of work and in receipt of sickness or disablement benefit. The rule in question, which was drawn up with the concurrence of the advisory committee composed of representatives of approved societies of all types, merely sets out the restrictions which a society should impose on the activities of a member whom they have already decided to be incapable of work. The Ministry does not lay down any definition of light work as it rests with each society to interpret its own rules in applying them to any particular case which may arise.

MONDAY, JUNE 13TH.

Dentists Bill.

The House considered the Dentists Bill on Report.

Colonel WEDGWOOD moved an amendment to Subsection 3 of Clause 1, excluding from the provisions of the Bill the extraction of teeth without fee or payment. Frequently in domestic life, he said, the mother of a family had to extract a loose tooth from a child's mouth. He wanted it made perfectly clear that a mere domestic extraction of that kind should not be treated as a crime.

Sir A. MOND said that he made it clear in Committee that they took out the words "without fee or reward" because they wished to prevent unqualified people starting practice by undertaking to extract teeth without fee or reward, on the understanding that they would be able to sell artificial teeth to those people, thus by some camouflage defeating the whole object of the Bill, which was to prevent unqualified people tampering with the teeth of the nation. Something in that direction was long overdue. A mother taking out the tooth of her child could not be held to be practising dentistry, either directly or by implication.—The amendment was withdrawn.

Colonel WEDGWOOD moved the adjournment of the debate.—Lieut.-Commander KENWORTHY seconded the motion. He was not opposed to the Bill, but he had received many communications from dentists in his constituency asking for amendments, not wrecking amendments. Owing to the way in which the Bill had been brought in he had not had time to put them on the paper.—Sir A. MOND resisted the motion to adjourn the debate. Long negotiations had taken place between all the parties affected, and practically it was agreed that after the Bill passed through Committee the Report stage should be treated as agreed.—Colonel WEDGWOOD: Agreed by whom?—Sir A. MOND: By representatives of the registered and unregistered dentists.—Colonel WEDGWOOD: What about the public?—Sir A. MOND: The Minister represents the public, and it is in the interests of the public that the Bill should be passed.—Colonel WEDGWOOD said the Report of the Departmental Committee included a great deal more than the putting of the dentists in the same category as the doctors. It included also a free dental service. It also included some form of scholarship which would enable children of the working class to become practitioners. All that had been dropped. Dentistry had been made a close corporation, confined, like medicine, to the children of the middle and upper classes, and ruling out those who were dental mechanics.—Mr. LAWSON asked what guarantee the public had got against monopoly prices for dentistry.—The motion to adjourn the debate was negatived.

On Clause 3, which deals with the right of certain persons to be admitted to the Register, Colonel WEDGWOOD moved an amendment to substitute for the words "prescribed examination," "a modified examination." His object, he said, was to ensure that dental mechanics should not be called upon to pass a very stiff examination such as would be necessary for future aspirants.—Sir A. MOND resisted the amendment and urged that the word "modified" meant nothing.—The amendment was negatived.

The Report stage of the Bill was completed.

On the motion for the third reading of the Bill, Colonel WEDGWOOD moved the rejection of the measure.—Mr. MYERS seconded.—Major MOLSON advocated the passing of the Bill in the interests of the public and not in the interests of any branch of the profession. As to the question of a monopoly, he thought Colonel Wedgwood seemed to forget that they were going to double the number of qualified dentists in the country, and if they increased the supply surely that was the best way of reducing the price. The quality would improve.

The Bill was read a third time and passed.

TUESDAY, JUNE 14TH.

Financial Position of the Hospitals.

Colonel MILDMAY asked the Minister of Health whether he could find it possible to take steps which would result in immediate action based on the recommendations of Lord Cave's Report, with reference to the financial position of hospitals.—Sir ALFRED MOND replied: The matter is now before the Cabinet, and I hope to make an announcement on the subject in the course of the next few days.

Drunkenness Statistics.

Sir J. D. REES asked the Under Secretary of State for the Home Department, as Chairman of the Central Control Board (Liquor Traffic), the number of convictions for drunkenness in the scheduled areas of England and Wales during the past quarter of the current year; and the decrease on the figures for the corresponding quarter of 1920.—Sir J. BAIRD replied: The returns of the Central Control Board are compiled weekly. The most accurate information therefore which I can supply to my hon. friend is contained in the returns for the first complete 13 weeks of the year. They are as follows: 1920, 23,993; 1921, 19,854—decrease in 1921 as compared with 1920, 4139.

The Services.

OFFICERS' ALTERNATIVE PENSIONS.

THE Ministry of Pensions announce that officers and nurses disabled by Service in the Great War who intend to claim alternative retired pay or pension, based on pre-war earnings and present earning capacity, must make application before July 2nd, 1921, or before a year has elapsed since the first award of disability, retired pay, or pension, whichever is the later date. Applications for alternative pensions by widows of officers whose deaths were due to service in the Great War must also be made before July 2nd, 1921, or within a year of the date of first award of the flat-rate pension. A widow who may not be eligible at present owing to the receipt of allowances for children, but who may become eligible when these allowances cease must make application before July 2nd, 1921, in order to establish her future claim. A disabled officer is not eligible for alternative retired pay if his pre-war earnings did not exceed £132 a year (rather less for navy warrant officers), nor is a disabled nurse eligible for alternative pension if her pre-war earnings did not exceed £95 a year. In the case of officers' widows there is no fixed limit. As the substitution of alternative retired pay or pension for the ordinary flat-rate pension represents in some cases a substantial addition to the amount of the pension, disabled officers and nurses, and officers' widows who have not yet made application, should ascertain without loss of time whether they are entitled to the benefits of the alternative system. Applications and inquiries should be addressed to the Officers' Branch, Ministry of Pensions, Cromwell House Annexe, Millbank, London, S.W.1.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. J. H. Pead has been placed on the retired list with rank of Surg. Capt.

ROYAL ARMY MEDICAL CORPS.

The undermentioned temp. Capts. to be temp. Majs. whilst specially empld: H. St. A. Agate and A. G. Higgins.

The undermentioned relinquish their commns.:—Temp. Maj. J. F. O'Malley (and retains the rank of Maj.). Temp. Capts. (and retain the rank of Capt.): R. J. Snider and R. A. Shekleton.

ARMY DENTAL CORPS.

The undermentioned Dental Surgs. to be Majs: Temp. Maj. F. W. Shilton, from Spec. List; Flight Lt. (actg. Squad. Leader) C. L. Colbran, from R.A.F.

Flight Lt. D. Blair, Dental Surg., from R.A.F., to be Capt.

The undermentioned temp. Capts. to be Capts.: R. M. King, from Gen. List.

Dental Surgs. from Gen. List: D. Clewer, A. E. Webb, R. J. Condie, H. J. Procter, and H. L. McCallum.

Dental Surgs. from Spec. List: J. V. M. Byrne, F. H. W. Beer, A. T. Madin, and W. R. Wotton.

Lt. T. D. Corke, from Midd'x R., to be Lt.

The undermentioned temp. Capts. to be Lts. (with the temp. rank of Capt., but without the pay or allowances of that rank): J. Baillie and M. J. O'Reilly, Dental Surgs., from Gen. List.

Dental Surgs., from Spec. List: H. E. Flavelle, H. J. Higgins, and A. B. H. Cole.

TERRITORIAL FORCE.

Maj. W. Bryce is granted the rank of Lt.-Col., with permission to wear the prescribed uniform.

Capts. G. T. Willan and C. Corfield to be Majs.

Capt. E. S. Stork, from T.F. Res., to be Capt.

Capt. D. Stewart (late R.A.M.C., S.R.) to be Capt.

A. G. Williams (late R.N.V.R.) to be Capt.

D. M. Lindsay to be Lt.

DEFENCE FORCE.

C. I. Ellis to be temp. Col.

H. G. L. Allford to be temp. Capt.

2nd (Home Counties) Fd. Amb. (D.F.).—To be temp. Maj.: R. A. Freeman.

1st (W. Lancs.) Fd. Amb. (D.F.).—R. R. Thompson (Capt. R.A.M.C.) is granted the rank of temp. Maj.

1st (S. Midland) Fd. Amb. (D.F.).—To be temp. Capt.: J. H. Sheldon

1st (Highland) Fd. Amb. (D.F.).—To be temp. Maj.: F. M. Rorie.

1st (Welsh) Fd. Amb. (D.F.).—To be temp. Maj.: R. A. Beaver.

53rd Divl. San. Sect. (D.F.).—To be temp. Capt.: P. W. Kent.

INDIAN MEDICAL SERVICE.

The following relinquish their commissions:—Temp. Capts. Jitendra Mohan Ghosh (granted the rank of Capt.), Henry Richard Rishworth (granted the rank of Capt.), Chandragiri Rangabhashyam Naidu, Vasant Rajaram Masurekar, Kedar Nath Goyal, Teja Singh Uberoi, Justinian Anthony daCosta, Muqatlal Damodardas Munim, Ardeshir Dadabhoy Shroff, Ram Singh Sharma, and Lieut. George Fredrick Andeen.

Temp. Capt. Bantwal Shankar Rau is granted the rank of Capt. on relinquishing his temporary commission.

Mr. F. E. De B. Pim, L.R.C.P., L.R.C.S. Irel., has been appointed a Knight of Grace, and Mr. R. D. Thomas, L.R.C.P., L.R.C.S. Edin., an Esquire, of the Order of St. John of Jerusalem in England.

Appointments.

CHISHOLM, A. E., M.B., F.R.C.S. Ed., has been appointed Obstetric Physician and Gynæcologist at the Royal Infirmary, Dundee.

FERNANDO, H. M., M.D., B.Sc. Lond., a member of the Executive Council of the Island of Ceylon, and an Unofficial Member of the Legislative Council of that Island.

MCARTHUR, J., L.R.C.P. & S. Edin., Medical Officer of Health to the Conisborough Urban District Council.

MATTHEWS, E. W., M.B., B.S. Lond., D.P.H., Medical Officer of Health for Kingston-on-Thames.

PICKEN, R., M.B., C.M. Glasg., Medical Officer of Health for Cardiff.

RAINY, H., M.D. Edin., Medical Adviser to the Prison Commissioners for Scotland.

Certifying Surgeons under the Factory and Workshop Acts: GIBBON, J. G., M.D. Dub. (Mullingar); CROWLEY, T., L.R.C.P. & S., Irel. (Wath-on-Dearne); SAVERY, W. M., L.R.C.P. Lond., M.R.C.S. (Evesham).

Vacancies.

For further information refer to the advertisement columns.

Aberdeen Royal Asylum.—Temp. Jun. Asst. P. £250.

ROYAL EARLSWOOD INSTITUTION.—The seventy-fourth annual report (1921) of the Earlswood Board of Management conveys the welcome information that the residual estate of the late Mr. W. H. Ray has now been made available and £30,000 realised to extinguish bankers' loans and other outstanding liabilities. The largely enhanced current expenses still call for liberal support on the part of subscribers. The report of the medical superintendent, Dr. C. Caldecott, shows that during the year 1920 the average number of patients resident was 442, 281 males and 161 females, 47 admissions, 37 discharges, and 14 deaths being recorded; 23 were admitted by "election and part payment," 21 on "payment," and four were "aided by local committees." A few of the new cases raise hopes of improvement from training, but there is also a considerable percentage of hospital cases. Twenty-six of those discharged were reported "improved," and a youth of 21 was discharged by the Visiting Justices as "recovered." The death-rate was low—i.e., 3·16 per cent. to the average number resident. Pulmonary tuberculosis was responsible for four deaths (28·5 per cent.), and there was also a case of intestinal tuberculosis. The number of epileptics in the institution represents the percentage of 13·31 to the average number resident, and the occurrence of no less than 9107 fits was recorded during 1920, three patients, accounting between them for 3137 of the above, having died in the "status epilepticus." Considerable reorganisation seems to be in progress in the educational departments of the establishment, including special instruction of an interesting character for low-grade and infant cases; while the industrial and trade work, for which Earlswood has so long been noted, is fully maintained.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

Tuesday, June 21st.—5 p.m., Croonian Lectures:—Dr. F. L. Golla: The Objective Study of Neurosis.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, June 20th.—2 p.m., Dr. S. Pinchin: Medical Out-patients. Dr. Simson: Diseases of Women. Dr. Morton: X Ray Department. 2.30 p.m., Mr. Baldwin: Visit to Surgical Wards. 5 p.m., Lecture:—Mr. D. Armour: Diseases of the Gall Bladder and Ducts—Treatment.

Tuesday, 21st.—10 a.m., Mr. Steadman: Dental Department. 11 a.m., Dr. McDougal: Electrical Department. 12 noon, Mr. T. Gray: Demonstration of Fractures. 2 p.m., Mr. Banks Davis: Diseases of the Throat, Nose and Ear. 2.30 p.m., Mr. Addison: Demonstration of Cases, Surgical Wards. 5 p.m., Lecture:—Dr. Pernet: Some Bullous Eruptions.

Wednesday, 22nd.—10 a.m., Mr. MacDonald: Genito-Urinary Department. 12 noon, Mr. Sinclair: Surgical Diseases of the Abdomen. 2.30 p.m., Mr. D. Armour: Demonstration of Cases. 5 p.m., Lecture (II.):—Mr. Baldwin: Surgery of the Rectum.

Thursday, 23rd.—10.30 a.m., Dr. Simson: Gynæcological Demonstration. 12 noon, Dr. S. Pinchin: Diseases of the Heart. 2 p.m., Mr. MacDonald: Surgical Out-patients. 2 p.m., Mr. B. Harman: Eye Department. 5 p.m., Special Lecture:—Dr. J. C. Bridge: General Practitioners and the Prevention of Industrial Diseases. (Open to all Medical Practitioners.)

Notes, Short Comments, and Answers to Correspondents.

THE CREATIVE FORCE AS A FACTOR IN THE ECONOMIC PROBLEMS OF WOMEN'S WORK.

BY PROF. A. LOUISE MCILROY, D.SC., M.D. GLASG.

NOWADAYS, when sex problems are so much a subject of discussion, we are inclined to take the view that sex is the dominant factor in almost all relationships of life. If we substitute the words "creative force" for sex, this is to a great extent true. The creative energy in the normal individual has as its main object the reproduction of the species, just as in the animal kingdom as a whole. When this creative force is not used for reproductive purposes, the question arises whether it can be employed in other directions beneficial to the community.

Sex Instinct as a Motive Force.

The world permits to men a sex instinct in the narrow sense, and condones its exercise as being the natural outlet for a physiological necessity. With women, on the other hand, it is held that sex is dormant and should only be called forth on marriage; that at the best it is an instinct which should not only be controlled, but in the minds of many prudes, even to-day, should be completely denied or hidden. Why should the maternal instinct in a mother be so lauded and the sex instinct so despised? Surely one is bound up with the other. Under modern conditions of so-called civilisation the natural outlet for sex instincts is not always to be obtained for every individual. That sex or creative energy must, therefore, be enlisted for the benefit of the community in other directions. It must be remembered that it is during the reproductive phase of life that all the greatest work of the world has been done. It is just the sex energy which has been deflected into the work which has given so much of its value.

The solution of sex problems thus lies not in the perversion of sex instincts, but in the direction of sex energy into such channels as will make it the motive power for great work of invention and research. The sexual instinct is the ultimate force which gives the energy, the keenness, the enthusiasm to all work, although the individual may be perfectly unconscious of the source of his or her activities.

Individuals suffering from neuroses or warped by unsatisfied sex instincts are as a rule leading misdirected lives. Given work to do in which they can use their creative energy, happiness and contentment is in most cases within their grasp. The physical satisfaction of sex is not an absolute physiological necessity for either men or women, but an outlet must be found in each individual for the creative force. In some individuals the sex instinct remains unsatisfied after mere union; in women it is often the maternal instinct which calls loudly for satisfaction. Women who dwell upon sex problems—to their own great unhappiness—are not necessarily over-sexed individuals; they are suffering from the exuberance of unemployed creative energy. The outlet to this energy may lie in original researches in art, science, or literature, or in work of the utmost value to the State. The products of such work are the children of the brain, and although sometimes the worker may long for more tangible children, on the whole she will be content.

Creative Work and Reproduction.

As a result to a great extent of the war there has been an upheaval in the world's attitude towards the more serious side of women's work, and problems which were formerly only of academic interest have now to be faced owing to the increasing numbers of women who have obtained the opportunity of engaging in work of a higher nature, entailing the expenditure of much energy in specialised directions. Women have proved that their work may equal that of men; the problem is how such work is to fit in with that of motherhood and care of a family. When we consider the training and education of girls for the higher branches of the professions we are faced with the problem of the possible influence of her activities on her reproductive functions and conversely of the possible influence of marriage and motherhood on her career.

The problem is further complicated by the fact that it is not always possible for women to marry, owing to various domestic, economic, or other circumstances, nor have they always an opportunity of doing so. Man chooses his mate; woman can only make a selection from possible candidates. In many cases, therefore, she is denied the opportunity of male companionship and the maternal joys which go to make a home, which are the highest functions a woman can fulfil, both for her own individual happiness and for the prosperity of the race. Such an ideal existence is one which is approved by the best and most intellectual women of the day, but it mostly involves the sacrifice of independence and freedom, and retirement into comparative oblivion. This retirement has many compensations, but these do not necessarily appeal to every woman, and as a consequence much of the business of the State is carried on by the large number of voluntarily unmarried women, who by their contribution of work become more or less the mothers of this State. It is these women who, for example, are in a position to come forward at the time of a national crisis and offer help. Few would object to the praise and publicity which is their reward, praise which only half makes up for the absence of home ties.

The Clash of Interests.

We cannot as yet judge of the results of the higher education of women as a whole, nor can we form opinions as to the capacity of women for special branches of work. Public opinion at present encourages men workers to marry but puts every difficulty in the way of the marriage of women workers. Some departments of the State even debar them from the continuance of their work after marriage. Celibacy, therefore, becomes voluntary for men, but for women workers in most fields it is more or less compulsory, at least so far as motherhood is concerned. One result is that among women workers who do marry the birth of children is often prevented by contraceptives, the use of which must offend at least the æsthetic sense. Existence for a woman under such conditions is an abnormal one. Apart from the temporary dislocation of interests caused by a love episode, marriage brings gain to the work of a man, unless he is hampered by family or financial worries which cannot be put down to marriage per se. Man's creative force as regards actual reproduction entails little strain upon his work; it is often a thing apart; but with woman, at the time when it is being physiologically exercised, it is more or less her whole existence. Marriage may be said from the point of view of specialised work, such as research work, to be the handicap of a woman's professional career. The care of offspring before birth and for some years after entails the expenditure of much energy. I do not for a moment suggest that because this function is being exercised all married women should be debarred from work. That is entirely a matter for the decision of the individuals concerned; and it must not be forgotten that the offspring of a mother who augments her husband's income is often better off by the increased financial advantages. It is in higher and more specialised forms of work, where the individual counts so much, that the problem is the greatest. In such work, the mere time spent at research is not sufficient in itself, but original ideas must be given out, and the creative force used almost to the uttermost in its attempts to wrest from Nature the secrets so carefully stored and hidden from us. If a woman engaged in such work endeavours at the same time to lead the life of a mother what will be the result? In her work she is placed at a disadvantage in her competition with men working in the same branch; she attempts to do the work they find all-absorbing in addition to the rearing of her family. Too great a strain is put upon her mentally and physically. Should she fail in either or both, the finger of scorn is at once raised and she is used as an example of the futility of women aspiring to do the work of men. In practice, with very few exceptions, it works out that one or other gets neglected. Even when domestic difficulties are got over, and home worries wiped out, the question whether a mother can give her whole-hearted attention to her research work still remains to be answered. If creative energy is directed or distributed in several directions, work must suffer.

No Immediate Solution.

Woman therefore must make a more or less definite choice between her heart and her head, or compromise by giving up her work while she is exercising her reproductive functions. Experience shows, however, that it is difficult to take up work again later, when fresh competitors may have entered the field. Yet it seems hardly just or fair that a certain section of research workers should take the unspoken vows of celibacy, and sacrifice themselves to a life without the companionship which is just as desirable for a woman as for a man. Are the more attractive women to remain untrained for the higher careers just because of the possibility of marriage? Should only the unattractive be chosen and urged onwards? Who is to judge which is which? There may be no solution to these problems, but we must remember that the widest sympathy and understanding is only got by knowledge, and the educated woman may become singled out all the more readily as a fitting companion by a man. No one can foresee how many members of a school or college will survive the temptations and attractions of marriage and motherhood, nor whither we are tending in these matters. We can only work blindly on, trying to develop character by training and letting the gods decide as to the ultimate best. All women should be given an equal chance of development and culture, and their subsequent choice between careers must be an individual one. Whatever a woman's decision, the world will doubt its wisdom, and so, on occasion, will she herself. But that is no reason to deprive her of the opportunity for free choice, from which alone some measure of contentment after the conflict may be hers.

COLONIAL HEALTH REPORTS.

Gold Coast.—In a report prepared by Mr. G. C. B. Parish, Assistant Colonial Secretary, on the Blue-book for 1919, it is stated that at the census of 1911 the population of the Gold Coast and Dependencies was 1,503,386. The number of Europeans resident in the Colony during 1919 was 3182, as against 1823 in 1918, there having been an increase of nearly 200 per cent. in the mercantile community. A summary of the chief causes of death shows 22 per cent. due to the intestinal group of diseases, 12 per cent. to the pneumonia group, and 5 per cent. to tuberculosis (including phthisis), while senility and prematurity accounted for 11 per cent. each. Registration not being general all over the colony no accurate statement of infant mortality can be given, but as in Accra 28 out of every 100 deaths registered are those of infants it must be presumed that the proportion of those born in the colony who fail to reach their first birthday must be high. The death-rate amongst Europeans resident in the colony during 1919 was 8·8 per 1000, as compared with 30·7 in 1918 (the year of the influenza epidemic); the invaliding rates per 1000 for the same periods were 23·27 and 55·4 respectively. Amongst European officials in 1919 1 death was due to influenza, 1 to yellow fever, 1 to blackwater fever, 1 to liver abscess, 1 to chronic gastritis, and 1 to accident. Of the 15 deaths of European non-officials, 7 were due to blackwater fever, 1 to thermic fever, and the others to miscellaneous diseases. Seven European non-officials were invalided with blackwater fever, 1 with kala-azar, and 1 with yellow fever. Treatment was given in 3758 cases of malaria, 458 of dysentery, 9 of yellow fever, 277 of pneumonia, and 269 of tuberculosis. 16,943 successful vaccinations were performed; 14 cases of sleeping sickness were treated. Of 20 cases of blackwater fever treated, 8 proved fatal, and of 9 cases of yellow fever, 5 proved fatal. The special features of 1919 were the comparative drought and a severe epidemic of cerebro-spinal fever in the north-western extremity of the colony, 91 per cent. of the cases being fatal. The rainfall in Accra was 20 inches as compared with an average of 32 for the previous 10 years. The climate, though hot and damp, is cooler than that of most tropical countries situated in the same latitude. It is not in itself unhealthy, but an evil reputation has been earned for it in the past by the prevalence of mosquito-borne diseases, against which all possible precautions have constantly to be taken. The Gold Coast is peculiarly free from many of the discomforts associated with tropical countries: hot nights and intense heat by day are the exception rather than the rule, while insects are comparatively unobtrusive. The efforts of the sanitary and medical authorities in promoting hygiene and treatment of disease continue to exercise a beneficial effect on the general health of Europeans.

British Honduras.—Mr. Eyre Hutson, C.M.G., Governor of the Colony, reports that the estimated population in 1919 was 43,586. The birth-rate for the year was 33·979 and the death-rate 27·555 per 1000. The proportion of illegitimate births was 42·40 per cent. Rain fell on 187 days in the year in Belize and amounted to 68·93 inches. The daily average number of patients under treatment and care in Belize Hospital was 45·63, in Coroza Hospital 8·61, in Orange Walk Hospital 6·11, in Stan Creek Hospital 6·32, in Toledo Hospital 7·14, and in the Lunatic Asylum 56·45.

AN AMPHIBIOUS BOAT-TRAIN.

The *Economic Review* for June 10th tells of experiments with a new system of waterway transport, described alternatively as the "amphibious boat" or the "amphibious train," which have been successfully carried out on the Willebroeck Canal in Belgium. The object of the system is to overcome transport difficulties on unnavigable portions of rivers, such as rapids, by rendering craft easily transferable to land while loaded and conveying them by rail until their further transport by water again becomes possible. It also contemplates the conveyance of the craft overland from one river or waterway to another. The inventor is a Belgian, Mr. Robert B. Goldschmidt, and it is hoped to make use of the system mainly in the Belgian Congo. The amphibious "boat-train" is described as a series of twin-boats or barges, the first of which is the tug, which can be driven by petroleum or palm oil. Each pair of boats is bound together laterally by a double yoke of steel, bearing a hanging device which runs on a mono-rail. The mono-rail is laid on a raised masonry or timber structure scribed so as to clear the hulls of the boats on either side. It is hoped that the boat-train will enable the great river system of the Congo, hitherto neglected, to be used regularly for transport, notwithstanding its frequent interruption by rapids.

A QUICK REPLACEMENT.

Whilst one of the members of the medical profession was attending to his duties his car was stolen. Within 48 hours of this he received a cheque from Messrs. L. A. Aldridge and Co., Ltd., of 23, Bucklersbury, E.C. 4, with whom he was insured, covering the full value of his car.

THE FREMLIN-ROGERS (STEAM) HYGIENISER.

The Fremlin-Rogers Milk Hygieniser shown in the illustration is designed for scalding milk in large or small quantities without the risks of burning, over-heating, or loss by boiling. The milk is poured into a basin-like receptacle, passing thence in a thin layer over a heated surface, the flow being regulated by moving a pointer over a graduated scale. In this process of scalding, bacteria are destroyed, the sudden rise and fall of temperature, it is alleged, ensuring this without damaging the nutriment or the chemical constituents of the milk, or lessening its vitamin content. The apparatus, which can be heated by gas, oil, or electricity, is made in various sizes, that depicted being a household hygieniser capable of dealing with one quart of milk in five minutes, or three gallons in an hour. It can be obtained from the proprietors, Milk Sterilisers, Ltd., 24, Buckingham Street, London, W.C. 2.

AN IMPOSTOR.

To the Editor of The Lancet.

Sir,—I should like to warn my colleagues in London hospitals of a person who describes himself as a gentleman. He called upon me on Saturday week whilst I was engaged in the out-patient department of the hospital to which I am attached, first of all asking the hospital beadle for the name of the "officiating" doctor. He then said he was urgently in need of the doctor and was admitted. When he confronted me it was to say that he was a member of a well-known Scotch family, the MacDougall's, and that he had wired to his brother—a general in command of troops at Fermoy—for money, as he and his wife were stranded in London without a penny. Could I lend him two sovereigns till Monday morning at 11? Foolishly, I was struck by his knowledge of the MacDougall family, of whom I knew, and lent him the money. The loan has not been returned, so I wish to prevent others from being victimised.

I am, Sir, yours faithfully,

June 13th, 1921. "O. P."

The great sale of surplus Navy and Army medical stores is continuing at the Disposal Board Depôt, Wood Lane, Shepherd's Bush, London, W.

An Address

ON THE

UNSOLVED PROBLEMS IN GYNÆCOLOGY AND OBSTETRICS.

Read by invitation before the American Gynæcological Society on June 2nd, 1921,

BY W. BLAIR BELL, B.S., M.D. LOND.,

PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY IN THE UNIVERSITY; OBSTETRICAL AND GYNÆCOLOGICAL SURGEON TO THE ROYAL INFIRMARY; OBSTETRICAL SURGEON TO THE MATERNITY HOSPITAL, LIVERPOOL.

TO-DAY gynæcology and obstetrics stand high among the developments of surgery along scientific and specialised lines; yet the more I think of this, the greater is my wonderment that it should be so. It seems such a short while since our specialties were struggling towards the light. When, therefore, I received your invitation to address this learned society, it occurred to me that it might not be inappropriate if I were to consider for a few moments the principal avenue through which approach may be made to the secrets still hidden from us, and the *personnel* and equipment required for the task.

I do not think there can be any doubt that the collective status of the gynæcologists and obstetricians of the world in regard to clinical acumen and surgical technique is nearing the limit which must be set to human achievement, and that the same will soon obtain in regard to the bacteriological aspects of our special subjects.

But in contradistinction to this must be placed the unsatisfactory character of our advancement—the slow progress we are making—in the more essentially biological, including biochemical, problems, connected not only with the normal morphology and physiology of the female genitalia, but also with the pathological developments that may be associated with the structure and function of the reproductive organs. Concerning the actual details of these problems I shall have but little to say, except by way of illustration.

EDUCATIONAL METHODS.

First, let me consider how far our present methods of education are conducive to the correct mental attitude of the future investigator, whether they are methods that stimulate the powers of perception and make every student an interested observer from the beginning.

It is a curious commentary on the value of the allied sciences to the surgeon of to-day that there is a growing tendency, at any rate in my own country, to minimise the importance of biology and to urge the superior—I might almost say "exclusive"—claims of the final hospital study; and the attitude is not confined to the student. This seems to me unfortunate, for it means that we are catering entirely for men of moderate intelligence and not at all for those on whom may fall the responsibility of sustaining progress in our science. As a result of our existing methods, the clinical aspects of gynæcology and obstetrics have been thoroughly illuminated, as I have said, while the more abstruse biological features are but very imperfectly understood and their claims hardly realised. It may be argued that there are many expert physiologists, biochemists, and comparative anatomists; and this is true, but alone they cannot help us because they do not yet know our difficulties, neither have they the clinical nor technical knowledge with which to guide their steps. Up to the present the teaching of elementary gynæcological anatomy and physiology has been conducted by the clinical instructor, because these subjects have been almost invariably ignored by the physiologist and anatomist. This means, generally speaking, that expert physiologists and anatomists have remained in more or less complete ignorance of these matters, and are, therefore, even now unaware of the hiatuses in our knowledge.

There can be no doubt, I think, that the man who continually has to face difficulties in practice is the one most likely to find the means of circumventing them, provided he have sufficient all-round knowledge and adequate facilities for his task. It is only natural, however, that each should turn his attention to those matters concerning which he is best informed. It is obvious, therefore, that if the many biological problems connected with gynæcology and obstetrics, which so far have baffled us, are to be elucidated we must modify the general plan of education in regard to those who may perchance attempt to throw light on what is now obscure and indistinct.

In attempting to indicate the direction in which educational improvement may be made, I shall doubtless merely give verbal form to what must already have taken shape in the minds of many. In our educational methods we are too apt, I think, to set store on detail. We should, I believe, aim at encouraging a comprehensive and inclusive outlook. We destroy originality by overloading the young mind with so-called facts which often are the easily deducible results of observation. Again, it seems to me that the different subjects of the general curriculum are taught in too disjointed and exclusive a manner. As gynæcologists and obstetricians we should have the right—and the same applies to teachers in the other branches of final medical study—to define the subject-matter of the physiological and anatomical courses. The anatomist should be required to demonstrate and teach comparative and human anatomy on the lines we desire, and the physiologist should be obliged to lead, by experiment and demonstration in the laboratory, more directly to what will be taught later in regard to the human subject. There must, in fact, be more coördination throughout. It would be better, for instance, if the key-subject biology were taught in such a way as to make the student realise that in it man is included in a wide generalisation with the lower animals, and that man is but the evolutionary physiological and morphological climax. The student should be more definitely impressed with the knowledge that in his biological and biochemical studies he is watching the evolution of man, that he is following the simple to the complex, and that what may be normal at one stage is pathological in a higher state of evolution—that hermaphroditism, for example, is normal in the earth-worm but abnormal in man. If the student could be imbued with some conception of the ultimate value of all his biological work, and could be taught not to look upon it as a separate and isolated obstacle to arrest his onward course, not only would his hospital studies be more interesting and more relatively important, but his mental attitude and outlook would be as much fitted for the investigation of biological as for the study of purely clinical problems.

THE WIDER SCIENTIFIC MENTALITY.

The present trend, then, of medical education in Great Britain has been towards the production of good clinicians, rather than of men with their minds alive to the biological—morphological and physiological, including biochemical—import of the phenomena they observe. I often wonder how far this question has been realised in America, this training of the student towards a wider scientific mentality. In Great Britain, where general practitioners are now being urged to coöperate in an investigation concerning the beginnings of disease, it is clear that there is a need of reform in our methods of education if we are to expect results on the lines I have indicated.

Supposing, however, that the student has been educated on these principles, in what circumstances and in what environment will he find inspiration, *and obtain the best results?* The establishment and success of clinical units and of units for group-study in North America and Canada may provide the answer. Their foundation is, of course, open to the interpretation that these systems have been brought into existence because the brain of the average intelligent man is incapable of grasping and understanding all the side issues that go to make up the sum of medical knowledge; and I have heard it stated by an advocate of them that this is their raison d'être. Moreover, it is said that only in them can material properly be utilised and the one-line worker find an immediate use for his output. While the last part of this statement is true, I cannot agree entirely with the first. A properly educated man of wide perception is not necessarily a man of encyclopædic knowledge, but, rather, one whose mind is so saturated with basic principles that the mosaic of detail falls into an orderly pattern under the influence of his prescient intelligence. A man with the index type of mind is rarely original, and is not, therefore, necessarily worthy of encouragement. I have already referred to this in regard to the education of the student.

Pasteurs are, of course, born not made, but I believe that useful imitations can be developed by proper education and training, imitations good enough in the helpful environment of which I have just spoken to obtain results. Because the great biological and medical discoveries in the past have emanated from the brains of men ploughing a lonely furrow, there is no inherent reason why men of similar intellect should not again arise and in the more perfect environment that can be assured to-day unravel the outstanding questions. Meanwhile it should be possible now for men of lesser ability with proper education and a perfect environment to surmount difficulties which the master-minds of the past, with their more limited opportunities, could not overcome.

I would once more urge the importance, so well recognised in this country, of clinical work going hand in hand with scientific laboratory investigations. You have many wise foundations, whereas we are sadly handicapped for want of them. We in Great Britain who are interested in the scientific aspects of our subjects have not the same facilities.

In this continent there is offered subsequently to the well-educated man every opportunity for attacking these problems at a living wage; but in Great Britain we cannot always secure the best men for the service of science, for we cannot offer them a reasonable financial reward, a reward in any way commensurate with that to be obtained from practice. This is a matter that is exercising us greatly, for times are changing, and while clinical matters are so well established that they can take care of themselves, there is urgent need that further progress which, as I have stated is largely biological, should not be crippled and hampered for want of proper organisation in teaching and post-graduate research.

If, then, the last ramparts of gynæcological and obstetrical diseases are to be captured we must modify to some extent our methods of education and we must bring correlation, breadth, and inspiration into the musty empiricism of the preliminary studies. I know the curriculum is overcrowded, but it is mostly with what could well be spared. We must, also, encourage scientific enterprise, and after educating our students for their life-work give them the opportunity of utilising their talents and of advancing the science of obstetrics and gynæcology.

I shall now endeavour briefly to substantiate my statement that the great outstanding problems in gynæcology and obstetrics are biological in the narrowest sense of the word.

MORPHOLOGICAL PROBLEMS.

The development of the human ovary can now be described with a considerable degree of certainty, but the same cannot be said in regard to that of the genital passages. To what factors, for instance, is due the fusion of the Müllerian ducts in the genital cord? This is of considerable importance in connexion with the common so-called malformations of the uterus and vagina. Prof. Wood Jones, who has done so much excellent work on the comparative anatomy of the genital organs, believes that we should look upon these conditions of imperfect union as atavisms rather than malformations; and in this light the comparative anatomy of the genitalia becomes both interesting and instructive. Indeed, it is from this point of view alone that information can be obtained. If serial sections be cut of the divided and uniting uterine horns in various species of rodentia and carnivora, all the later stages in the development of the human uterus may be seen. Moreover, it will be made clear that the human uterus has morphologically but two muscular coats and not three, as usually described. Nevertheless, we do not yet know what determines the final development of the human uterus, and we can hardly expect to know until we have decided definitely what are the variations in the factors that lead to the different degrees of Müllerian union that are normal, constant phenomena in closely related animals. In rodents there may be seen the complete didelphic condition with double vagina (viscacha) and the gradual evolution to the single vagina and bicornute uterus (agouti).

Again, can the peritoneal pouch that encloses the ovarian extremity of the tube and ovary itself, a structure seen in certain rodents, and, as I have found in a less complete form in hedgehogs, be passed over as a freak structure, in spite of the fact that, as Bland-Sutton has shown, it may exist as an atavism in woman? It seems to me that a structure so useful to fertilisation and conception is worthy of serious study, especially from the point of view of the state of peritoneal currents and other influences in the creatures concerned. An investigation concerning the nature of the secretion of these sacs would also be of considerable interest.

Let me take another matter which, possibly, is of more clinical importance. How far are we familiar with the causes of the irregularities in the female bony pelvis, apart from those resulting from gross postnatal disease, such as rickets? We talk about civilisation, athletics, and the rest, but what causes a generally contracted pelvis in a well-developed non-rachitic woman who has been guilty of none of the enterprises that militate against functional perfection?

The work of Whitridge Williams and others has demonstrated beyond reasonable doubt that the typical funnel-shaped pelvis is associated with high assimilation, but I do not think the cause of high assimilation is definitely known. Such an important matter, especially in this country, is deserving of extensive systematic investigation. Comparative racial studies, in which different races are examined in their natural environments, might throw considerable light on this and on other pelvic abnormalities. There can be no doubt that civilisation may greatly affect structure as well as function.

As a last morphological point of interest—albeit there are many others that will occur to all—let me say that I look forward to the day when some gynæcologist or obstetrician will give us the clue to the mode of origin of pathological new growths. After all the gynæcologist and obstetrician has, time and again, given a lead to the rest of the profession; and in the problem to which I refer he is on his own ground, for his work is chiefly concerned with the preservation of the structures and functions through the medium of which neoplastic developments normally occur.

PHYSIOLOGICAL PROBLEMS.

It is within the last 20 years that practically all the recognised facts concerning the female functions have been discovered. We now know, if I may quote one of my own aphorisms, that a woman is a woman on account of all her internal secretions.

and not only because she possesses ovaries. But we still lack certain evidence as to the nature of the controlling force that determines the primary sex-characteristics of the person concerned; nor do we know how it comes about that even in the course of development a conjunction of sex-characteristics may occur, a condition of hermaphroditism. Even if it be that the masculinity or femininity balance of the internal secretions is disturbed, this is still an effect, not a cause. That this fascinating and intricate problem is capable of solution I am convinced. It may well be the life-work of someone capable of estimating the gradual changes through the numerous classes of creatures that indicate the evolutionary origin of man—of some comparative morphologist with all the histological technique of the present at his disposal on which to graft new methods of observation; and then, when the gross serial steps have been demonstrated, he may perchance gain an inkling of that on which they depend, an inkling of the force which imbues the fertilised ovum of man with maleness and femaleness.

There are few, surely, who cannot recognise to-day the vast importance of femaleness as opposed to maleness, and few, too, who are not conversant with the essential physiological—that is to say, biochemical—differences that influence the mind and body. We have, too, some knowledge of what constitutes puberty. It is, we believe, the time of life when the metabolism has met the claims of somatic growth. The potentiality of a girl's metabolic resources at this time is such that it can support the strain of reproduction and all that this involves. But we do not know what happens at puberty to start the new train of events. What is the hormone that makes the ovary aware of the situation; is it then that the genital functions of the ductless glands come into being, and, if so, what leads to this awakening? That it is not a habit of life is too obvious to need discussion; it is due, rather, to a series of chemical events that may be altered and delayed by many circumstances of health and environment.

Nature of Menstruation.

Then, again, have we established without the possibility of fallacy the nature of menstruation? My view that it is an excretory process in regard to the principal elements required during pregnancy for the building up of the fœtus, and during lactation for the formation of milk, as is made evident by the calcium metabolism, requires full confirmation and elaboration in regard to the exact part played by the ovaries and other internal secretions.

To pass on, I would ask if there is general agreement concerning the factors involved in the production of the climacteric? I myself, for instance, disagree with those who think that the normal menopause is the result of primary ovarian atrophy, although many of the phenomena of the menopause are due to this change. The fact that the artificial menopause is produced by oöphorectomy has been a blind to all of us. If the ovaries are removed from a young woman with protracted amenorrhœa and ovarian destruction menopausal symptoms do not supervene. The artificial menopause is induced only when there has been pre-existing ovarian activity. At the commencement of the normal menopause the ovaries are normal and active, indeed, at the end of that phenomenon the woman may be capable of conception. Why is it that ovarian substance or extract of any kind, and in any combination whatever and however administered, does not produce specific results at the physiological menopause: whereas whole-gland ovarian substance, especially in association with thyroid substance, gives relief in case in which the menopause has been induced by operative procedures? There are some, I know, who will dispute this; but I believe the facts, as I have stated them, to be true. From this jumble—shall I say?—of observations it appears justifiable to ask you to consider as a working hypothesis for further investigations the view that there is at the climacteric some substance circulating in the blood, some natural biochemical toxin, or something withdrawn from it, which leads not only to ovarian atrophy but also to the other physiological and structural alterations that take place at the "change of life."

Another group of important correlated functions about which we know but little is that concerned with fertilisation and conception.

Selective Sterility.

I think that light will soon be shed on that curious anomaly I call "selective sterility." In view of recent additions to our knowledge in regard to the incompatibility of the blood of persons in different groups, it is not unlikely that selective sterility—as well as successful homoplastic, as opposed to autoplastic, ovarian grafting—will be found to depend on a similar, if not identical phenomenon. So far we know that a difference in the blood-grouping of married couples has no obvious relation to the possibility, or otherwise, of conception. Again, the normal inter-relations that exist between the mother and her fœtus in utero have been studied to some purpose; but we are still ignorant of the way in which the growing embryo controls the development of the chorionic epithelium that sometimes takes on such disastrous activity when the control is removed.

I do not think the theory that in such circumstances there is lutein over-growth is sufficient. It is common to see vesicular mole and chorion-epithelioma without abnormal lutein development.

Toxæmias of Pregnancy.

Moreover, how little we know concerning the toxæmias of pregnancy. It seems to me that before we can arrive at any proper idea of the disturbance produced we must know far more intimately the normal metabolic mechanism concerned and the maternal forces that are marshalled against the deleterious effects produced by what is, after all, a new growth in the uterus. If the recent work of Dold and Obata concerning eclampsia be correct, as seems possible, we shall be placed in possession of very interesting information concerning a biological phenomenon of vast importance, for I do not doubt that, if it be fully confirmed, we shall be able to test the blood of every pregnant woman before so serious a condition as eclampsia supervenes and to treat her with normal human serum. I have myself seen excellent results with blood-transfusion.

Although hundreds of thousands of human beings are expelled from the uterus daily we have but a faint glimmering of the biochemical factors leading to the determination of parturition. And what of lactation? Is the mechanism of the simple nature I have described in the Sex Complex? If so, we are little in advance of the ancients who, owing to their powers of perception, have always been worthy of consideration in matters of priority.

Such gynæcological and obstetrical problems seem to me almost infinite when I let my mind wander around the outposts of our small impregnable position of certain knowledge. I have, however, to-day the desire to emphasise not only the importance of those unsolved problems, which we all admit, but also the essential biological nature of them. I have attempted, too, to show that our education tends to drive us forward almost entirely along the deeply-trodden paths rather than along those barely to be seen or yet uncut through virgin country. I would plead, therefore, that our students and our post-graduates be more broadly educated at least in the great principles of biology, for I believe that only by way of physiological, especially biochemical research, and by the comparative study of simpler forms of structure shall we be able to bring our art towards scientific pefection.

The Relation
OF
HEART DISEASE AND PREGNANCY.

BY SIR JAMES MACKENZIE, M.D. EDIN., F.R.S.,
DIRECTOR OF ST. ANDREWS CLINICAL INSTITUTE.

IN FOUR SECTIONS—SECTION IV.

IRREGULAR ACTION OF THE HEART.

Significance of Irregular Heart Action.

THE importance of irregularity of the heart's action has not been sufficiently recognised. It is a matter seemingly so confused that few writers try to understand its real significance. Moreover medical knowledge had not until recently advanced far enough to enable physicians to differentiate its various forms.

This state of affairs is unfortunate, because a clear understanding of irregularity throws light on many obscure features of cardiac action and gives information of the most valuable kind in diagnosis, prognosis, and treatment. Indeed, the neglect of this subject renders a great part of the writings of physicians of little or no use. I have referred to Macdonald's description of cases of mitral regurgitation. In this description, as I pointed out, the incidental remark that the heart was irregular gives the clue to the real nature of the condition. An occasional reference such as this, if one is able to apply it, is often far more helpful than all the other details. Unfortunately, irregularity is usually considered so *unimportant* that it is not mentioned. Even when it is mentioned, the reference is often so vague as to preclude an exact differentiation and diagnosis.

But there is more than this. It is unhappily true that one can rarely trust a statement that the heart was irregular. I have often seen perfectly regular hearts described as irregular. Tracings of these showed beyond possibility of dispute that irregularity was not present.

I go farther than that and say that even when a sphygmogram is given the statement that the heart is irregular cannot always be accepted. I have just been looking at some sphygmograms taken by a physician in a case of pregnancy. One of these is described as "irregular." Certainly a casual examination seems to justify this description, for the pulse waves are of varying height. But when the length of each beat of the pulse is measured accurately, this first impression is disproved. The beats are of exactly the same length and are absolutely regular. Thus the apparent irregularity is artificial. I know from my experience in taking records, especially when there is laboured breathing, that the movements of the patient's arm will cause a marked variation in the height and depth of the waves, which in this instance was mistaken for an irregularity.

When, over thirty years ago, I began the study of irregular heart action, I was told that the subject was so difficult and confused that it was a waste of time to attempt such an investigation, and that in any case little benefit would result even if I happened to be successful. Even to-day, few physicians, and evidently no obstetricians, have made themselves familiar with this subject. As a consequence the subject is still shrouded in mystery; and where we get mystery we get fear, and we find people with irregularities treated like people with murmurs. We have, too, the same kind of prognosis—"the sign may be of no significance, but, on the other hand, it may be serious." As there is no clear differentiation, there is no certainty regarding the forms which are innocent and those which are of serious import.

Mechanism of Heart Irregularities.

The vast majority of irregularities can be classified in a manner which renders them easy of recognition by the unaided senses. This, I think, is of great importance, for it is obvious that if knowledge of this subject is to be utilised in practice, differentiation must be accomplished without apparatus and in a reasonably short space of time.

The manner in which the irregularities arise will be made clear by means of the diagram (Fig. 8).

FIG. 8.—Diagram representing the parts concerned in the movements of the heart, and the places of origin of the different forms of irregular heart action. *S.V.C.*, Superior Vena Cava; *S.A.N.*, Sino-Auricular Node; *A.*, Auricle; *C.S.*, Opening of Coronary Sinus; *A.V.N.*, Auriculo-Ventricular-Node; *A.V.B.*, Auriculo-Ventricular Bundle; *V.*, Ventricle.

This diagram represents certain structures concerned in the mechanism of the heart's movements. The heart's contraction starts at a small collection of peculiar fibres, the so-called sino-auricular node (*S.A.N.*) situated at the mouth of the superior vena cava (*S.V.C.*). The stimulus from the *S.A.* node causes contraction of the auricle (*A.*). From the auricle the stimulus passes to the auriculo-ventricular node (*A.V.N.*), the tissues of which resemble, in their structure, the fibres of the sino-auricular node. This *A.V.* node is situated in the wall of the right auricle near the opening of the coronary sinus (*C.S.*). The stimulus passes from the *A.V.* node along a bundle of peculiar cells, the auriculo-ventricular bundle (*A.V.B.*) to the ventricle (*V.*), where it breaks up into innumerable branches distributed to different parts of the ventricle.

While, in normal circumstances, the stimulus of contraction passes in this manner, i.e. from the sino-auricular node to the ventricle, yet each of the different parts, the auricle, the *A.V.* node, the *A.V.* bundle, and the ventricle, is capable itself of initiating a stimulus which can produce a contraction. The reason that the stimulus arises first in the *S.A.* node is that this tissue is most sensitive. After a stimulus of contraction has been discharged, no other stimulus can be discharged until a certain time has elapsed. This time is required in order that the tissue may recover its excitability. The rate of recovery is most rapid in the *S.A.* node. Thus, other parts of the heart are again whipped to action before they are able to discharge a stimulus of their own manufacture.

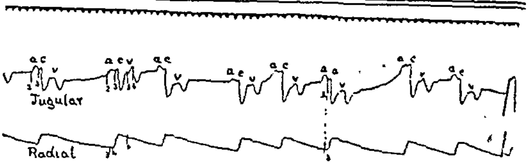

FIG. 9.—Simultaneous tracings of the jugular and radial pulses, showing an irregular pulse. The waves *c* in the jugular tracing are due to the carotid beat, and correspond in time to the pulse beats in the radial tracing. The wave *a* is due to the auricular systole, and it is seen that in this form of irregularity the auricles and ventricles equally participate—as shown by the waves *a* and *c*.

This is why, for instance, in complete heart-block, when the connexion between the ventricle and the upper parts of the heart is severed (as in damage of the *A.V.* bundle), the ventricle beats at a much slower rate than the auricle. In this condition the auricle may be contracting at the rate of 70 or 80 beats per minute, while the ventricle pursues an independent contraction at the rate of 30.

In abnormal circumstances the parts below the *S.A. node may become* so excitable that the stimulus may arise in them and set up independent contractions, which anticipate in point of time the stimulus for the *S.A.* node. This may occur occasionally in single beats, and so give rise to such irregularities as the extra-systole, which is due to premature contraction of the auricle or of the ventricle (Fig. 11). In the former case the auricular contraction precedes the stimulus from the *S.A.* node; in the latter case the ventricular contraction precedes the auricular or occurs at the same time. The premature contraction of auricle and ventricle may be continuous for a shorter or longer time, and so give rise to the various abnormal rhythms and the tachycardias (Figs. 20 and 21).

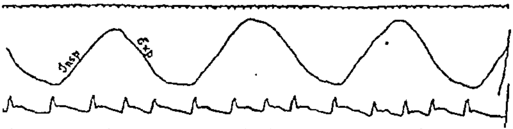

FIG. 10.—Tracings of the movements of respiration, taken at the same time as the radial pulse, showing that in the respiratory irregularity the rate of the heart increases during inspiration and becomes slower during expiration.

Differentiation of Heart Irregularities.

The places where the different irregularities arise are shown in the diagram (Fig. 8).

In the course of an inquiry into irregular action of the heart, I found that there were several groups of cases, and that these could be clearly differentiated on two grounds:

(1) On the ground of the mechanism by which they were produced; and

(2) On the ground of their clinical significance.

While the first basis of differentiation has been the subject of much research, the second has received far too little attention. This is due, I think, to the fact that the method by which knowledge of the kind required can be obtained has not been understood.

It is perfectly evident that, while an understanding of the mechanism by which an irregularity is produced is of profound interest and of great value, so far as the patient is concerned at any rate, knowledge of what is going to happen is of far more importance. To the doctor in charge of the patient such a knowledge is therefore essential to rational practice. This is particularly true in connexion with the problem of pregnancy, where an abnormal sign like irregular action of the heart may be present and must be interpreted.

It will be found that in pregnancy we have to deal chiefly with three forms of irregularity: respiratory irregularity, extra-systoles, and auricular fibrillation.

Respiratory Irregularity.

In this irregularity, which is probably the most common of all, the pulse is continuously varying in its rate. Simultaneous records of the radial artery and jugular vein show that the auricles as well as the ventricles participate (Fig. 9). While the irregularity can be clearly demonstrated by graphic records, it is necessary that the doctor should recognise it by his unaided senses. Advantage is taken of the fact that the alterations of the pulse are dependent on the respiration (Fig. 10). The pulse rate increases during inspiration, and slows during expiration. Frequently, however, this relationship cannot be recognised in a patient who is breathing normally; for a new stimulus has, in such cases, come into play before the effects of the previous one have passed off. Thus a confused sort of rhythm is encountered. When, however, the patient is made to breathe slowly and deeply the relationship of the altering rhythm, with the different phases of respiration, can be easily determined (Fig. 10). *I wish particularly to draw attention to this method of determining the* type of irregularity, as a doctor can apply it without any mechanical assistance. The character *of the irregularity is best made out* by listening to the heart at the same time as the patient breathes slowly and deeply.

The explanation of this irregularity is that a stimulus arises during expiration which *affects the vagus and so* produces the temporary slowing. On account of this fact the irregularity is sometimes spoken of as a "vagal irregularity," while on account of its association with the breathing it is called a "respiratory irregularity." Again, as it arises from a stimulation of the motor centre of the heart in the remains of the sinus venosus, it is called "sinus irregularity," to distinguish it from irregularities arising in other parts of the heart. There are, however, more than one form of sinus irregularity. I collected a large number of cases showing this irregu-

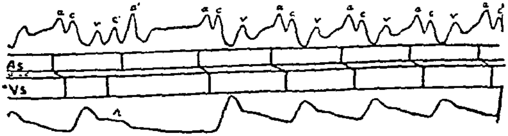

FIG. 11.—The upper tracing is from the jugular, taken at the same time as the radial (lower tracing). The interpolated diagram explains the events that happened in the heart during the period of irregular action. The down strokes in the space *As* represent the auricular systoles, and correspond with the *a* waves in the jugular tracing. The space *a–c* represents the passage of the stimulus along the *a–v* bundle, while the down strokes in the space *Vs* represent the ventricular systoles; and each corresponds with a pulse wave in the radial tracing. It will be seen that with one exception the auricular beat is followed by a ventricular beat. This one exception shows a wave *c'* in the jugular tracing, and a small wave *r* in the radial tracing, which occurs prematurely, i.e. before the auricular wave *a'*. These events represent what happens in the intermittent pulse, and show that the irregularity is due to a premature contraction (or extra-systole) of the ventricle.

larity, and found that the vast majority occurred in young people. The next most prevalent form of irregularity (the extra-systole) I found, on the contrary, to be most common in adults and elderly persons. So to make a distinction I called this "respiratory irregularity" the "youthful type," and the extra-systole the "adult type." I mention this differentiation as it has a distinct value in practice.

"Respiratory irregularity" is common in healthy young women, and in some women of maturer years, especially when there is present in the case a nervous element. It is a physiological phenomenon, indicative neither of disease nor of impairment. In no case should it be a reason for treatment or a bar to pregnancy.

The Extra-Systole.

This irregularity is due to a premature contraction of the ventricle, occurring independently of the stimulus from the auricle. It occurs usually at the same time as the auricular contraction or a little before it. Sometimes the auricle also contracts prematurely: this premature auricular beat is followed by a small ventricular contraction. Premature beats can be recognised as small beats in the pulse occurring too early and followed by a pause. Sometimes the small beat is not felt, and there seems to be a long pause in the pulse. The irregularity can thus be recognised without graphic record by feeling the pulse and auscultating the heart at the same time. When the pause in the pulse is felt the heart will give two short sharp sounds or one muffled sound, and this will be followed by a pause longer than usual (Fig. 12). A glance at the tracings and diagrams will explain the mechanism. If the pulsation in the jugular be observed during the pause of the pulse, a large wave may often be detected (Fig. 17). This is due to the fact that the auricular contraction is taking place at the same time as the premature ventricular contraction.

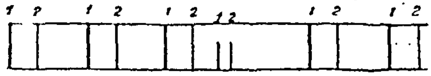

Fig. 12.—Diagram representing the sounds of the heart during an extra-systole.

The auricle cannot send its blood forward into the contracted ventricle, and so sends it back into the jugular vein.

Doctors should familiarise themselves with these clinical phenomena, as this form of irregularity and the "respiratory irregularity" constitute the great bulk of irregular heart actions. I repeat that both of them can, as a rule, be recognised by the unaided but trained senses.

My inquiries into the significance of this form of irregularity, which were pursued by watching large numbers of active people who showed it, revealed to me the fact that it is of no grave clinical significance. If heart failure did occur in people with extra-systoles, there were always other conditions present to account for it. So that, when this irregularity is the only abnormal sign it can be ignored so far as the prognosis is concerned; if heart failure is present, then the prognosis should be based on the other signs and not on the extra-systole.

So far as pregnant women are concerned I found extra-systoles present in 50 per cent. of healthy cases.* Usually they occurred at rare intervals and their detection was often accidental. Occasionally they were of frequent occurrence. In all cases the pregnancy was completed and the confinement passed with no trouble. I have in addition followed many women for 20 and 30 years, and the results justify this view.

Auricular Fibrillation and Paroxysmal Tachycardia.

The form of irregularity which is most commonly associated with heart failure in women at the child-bearing age is that due to fibrillation of the auricle. In this condition the muscle fibres do not contract in unison as in the normal beat, but each fibre twitches and contracts independently. The result is that the auricle is to all intents and purposes functionally inactive.

The Discovery of Auricular Fibrillation.

It was this inactivity which led to the discovery of the condition. I had recognised that in mitral stenosis of a progressive type changes slowly took place in the murmurs. I was therefore watching the course of the disease in a number of my patients whom I had attended many years earlier for rheumatic fever. In one case, a woman whom I had under observation for 17 years, there had for many years been present signs of auricular activity; for example, a presystolic murmur, and the wave in the jugular pulse, which I had come to associate with the beating of this chamber of the heart. There had also been present well-marked pulsation of the liver, due, mainly, to a wave caused by the auricle.

The patient was suddenly seized with great breathlessness on exertion, and developed a rapid and irregular heart (Fig. 5). When her heart had quietened down under digitalis I was surprised to find that there was, now, no presystolic murmur, nor any waves due to the auricle in either jugular or liver pulse. In fact, at the time the heart had become irregular all signs of auricular activity had disappeared. I assumed that the auricle had become paralysed, and in my early writings I described the condition as paralysis of the auricle (see Figs. 13 and 14, and also Figs. 6 and 7, The Lancet, June 18th, p. 1284).

Relation of Auricular Fibrillation to Extreme Heart Failure.

The light thrown by this case led me to search for other cases with this irregular action, and to watch other patients who suffered from mitral stenosis. As a result I found the irregularity to be far from infrequent, and I was so fortunate as to detect its onset in a number of instances. This led me to a study of heart failure in its relation to this condition. I worked also to discover the best means of combating the trouble. There followed the discovery that probably 80–90 per cent. of all cases of heart failure with dropsy and enlarged liver are due to auricular fibrillation. Further I convinced myself and others that the astonishingly good effects of digitalis are practically confined to patients with this irregularity.

Effect of Fibrillation of the Auricle on the Ventricle.

The normal rhythm of the heart (due to the production of a stimulus in the sino-auricular node at the mouth of the superior vena cava) has already been described. When the auricle passes into fibrillation it ceases to contract as a whole, and the orderly discharge of the stimulus to the ventricle is interrupted. The twitching muscle pours forth a rapid series of irregular stimuli, so that the auriculo-ventricular node is assailed by a great number of weak demands. Only certain of these—the actual number would seem to depend on the susceptibility of the auriculo-ventricular node and the bundle—pass through to the ventricle. The ventricular contraction is a normal one, but as a rule the rate of the ventricle becomes greatly increased, and the rhythm very irregular (see Fig. 5, The Lancet, June 11th, p. 1235). There may, however, be exceptions.

---

* This was the percentage I found on examining 100 cases about thirty years ago. I have looked for my data, but I have lost the references and the notes of most of my cases. Among those of which I do possess records the percentage is not so high. The matter is not, however, of much consequence.

Thus, in a case in which for many years there had been a delay in the response of the ventricle to the auricle, due to a slight damage of the auriculo-ventricular bundle ("partial heart-block") and in which the rhythm was regular and the rate about 60, the onset of auricular fibrillation did not quicken the pulse. It did produce the characteristic irregularity. This patient was not conscious of the onset of the abnormal rhythm, and his response to effort was not impaired. In the vast majority of cases, on the other hand, the onset is not only accompanied by a great increase in rate, but also by a great limitation of the field of response to effort. Indeed, in eliciting the history of the condition one can often determine the moment of onset with great accuracy, for the patient will state that he was quite well until some effort—for example, hurrying up a hill—induced marked breathlessness. From that time onwards he has been breathless on slight exertion.

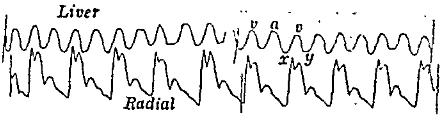

FIG. 13.—Simultaneous tracings of the liver and radial pulses in a patient with mitral and tricuspid stenosis, before the onset of auricular fibrillation. There are two waves *a* and *v* during the cardiac cycle. (See Fig. 14.)

From the fact that the heart beats are not only small and rapid, but also irregular, it can readily be understood how ineffective the circulation is bound to become (Fig. 5). Moreover, the rapid rate of the ventricle leads to exhaustion, so that heart failure speedily supervenes. This is in striking contrast to the absence of heart failure, when the rate is not increased as in the case just cited. When, in addition, there is a damaged ventricle, the rapid rate leads directly to a fatal issue.

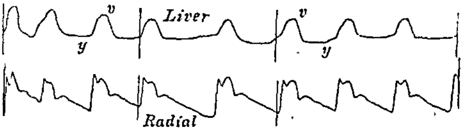

FIG. 14.—Simultaneous tracings of the liver and radial pulses after the onset of auricular fibrillation. There is but one wave now in the liver pulse during the cardiac cycle, the wave *a* having disappeared, and the presystolic murmur has also disappeared, and the rhythm is irregular. (Compare with Fig. 13.)

Principles of Treatment in Auricular Fibrillation.

Recognition of the fact, then, that the rapid rate leads to exhaustion of the heart muscle, and so to an inefficient circulation, gives us the data for applying a rational treatment. We must slow the heart. For even with auricular fibrillation the circulation is efficiently maintained when the rate of contraction is slow.

Study of the effects of digitalis and strophanthus in these cases showed that those drugs act by diminishing the rate in a most remarkable manner. I have repeatedly seen patients in dire extremity from heart failure (dropsy, orthopnœa, Cheyne-Stokes respiration), with a pulse-rate of from 120 to 150, lose all their distressful symptoms under digitalis, and that speedily. The rate would fall to 60 or 70 beats. Relapses, too, which are apt to occur, could be warded off for years by the judicious administration of that amount of the drug which maintained the rate at from 60 to 80 beats when at rest.

The Recognition of Auricular Fibrillation by the Unaided Senses.

The symptom by which the clinical observer can most readily recognise auricular fibrillation is the character of the pulse. The pulse rhythm is usually irregular, and this irregularity is of a very disorderly kind (Fig. 15, also Figs. 5, 7, and 14). In this respect it differs from most other arrhythmias. These, as we have seen, possess distinctive characters of their own. Thus, the irregularity in the heart of the young is marked by the fact that variations in rate coincide with phases of respiration; the intermittent pulse, due to extra-systoles, by the fact that the irregularity breaks in on an otherwise regular rhythm. In auricular fibrillation the length of the pauses between the beats is, as a rule, continually changing, the pauses between two succeeding beats seldom being of the same duration; moreover, succeeding beats are rarely of the same strength. The character of these phenomena will be made clear by the radial tracings in Fig. 15. These tracings were taken from five patients.

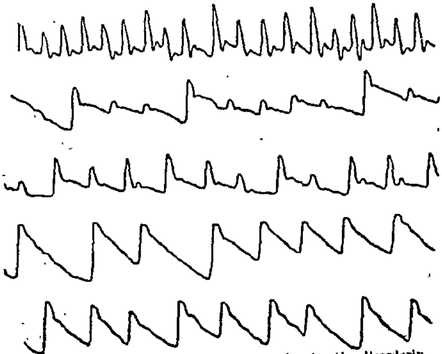

FIG. 15.—Tracings of the radial pulse, showing the disorderly irregularity characteristic of auricular fibrillation from five different patients.

Murmurs of Mitral Stenosis in Auricular Fibrillation.

I have already stated that, with the onset of auricular fibrillation, all evidences of auricular systole disappear. Thus in a patient with mitral stenosis, whose condition has been revealed by the presence of a presystolic murmur alone, or by a presystolic murmur accompanied by a diastolic murmur, auricular fibrillation causes the presystolic murmur to disappear. The diastolic murmur remains, for the reasons already given. When the heart is beating rapidly the diastolic murmur may fill up the interval between the second and first sounds, and physicians are then apt to assume that it is presystolic in type. If, however, the heart be auscultated during one of the long pauses which frequently occur, or after the rate has decreased—for example, owing to the administration of digitalis—the murmur will be found to follow the second sound, and there will be noted an appreciable silence before the first sound occurring at the exact moment at which the presystolic murmur was wont to be heard (*see* Figs. 6 and 7). This is a feature which even experienced clinicians seldom detect unless they specially seek for it.

Bearing of Auricular Fibrillation on Pregnancy.

My experience of pregnancy in women with auricular fibrillation is limited to half a dozen cases. This may seem a small number, yet if it be considered that these cases occurred at a time when I had a midwifery practice of 40 or 50 confinements a year, it will be seen that altogether there must be a considerable number. All my cases gave a history of rheumatic fever; all had mitral stenosis. In each case the advance of pregnancy was accompanied by increasing signs of heart failure—limitation of effort and œdema of the lungs as already described. In all but one, premature labour set in between the sixth and seventh months. All lived through the confinement, but none ever recovered the same degree of health as was enjoyed before the pregnancy. I actually saw none patient in two pregnancies. She made a fair recovery. In the others heart failure increased gradually till they died within two years of the pregnancy.

Judging by my own experience, I believe that though pregnancy does not produce an immediately fatal heart failure, it so weakens the organ that it hastens the fatal issue. In saying this, I recognise that my experience is limited. At the time at which five of these cases were under my care I had not recognised the nature of auricular fibrillation, nor had I learned how to give digitalis in this condition. In the one case which occurred after I had acquired this knowledge, I think I was able to help. The matter, however, requires far more investigation than I have been able to undertake. I leave it here, trusting that others, fortified by the knowledge now available, will carry out a more thorough inquiry.

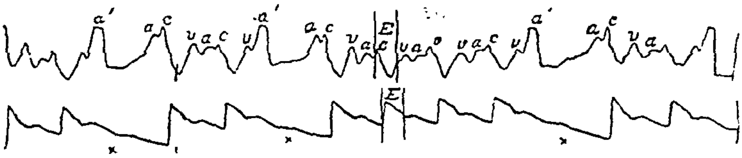

FIG. 17.—Simultaneous tracings of the jugular and radial pulses during irregular action of the heart. The auricle preserves its rhythm, there being a larger wave (*a′*) during the pause in the radial pulse. At this time there is a premature contraction of the ventricle, so that the auricular and ventricular contractions occur at the same time, and the contents of the auricle, not being able to enter the ventricle, are thrust back into the jugular, causing the larger wave *a′*.

In the meantime I would lay it down that auricular fibrillation is a bar to pregnancy. Should pregnancy have occurred, careful observation of the patient must be maintained. If the pulse rate exceeds 80 when at rest, digitalis should be given and continued until the rate falls to between 60 and 70 per minute. If œdema of the lungs, orthopnœa, or enlarged liver supervenes, the pregnancy should be terminated forthwith.

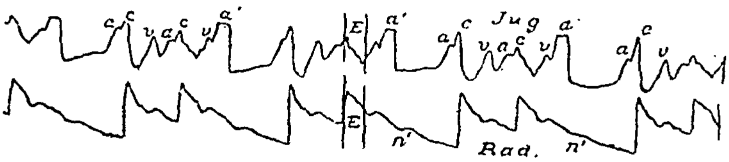

FIG. 18.—Shows the same thing as Fig. 17.

Paroxysmal Tachycardia.

There are other abnormal rhythms which may have to be considered in relation to the pregnant state. The most common of these is a condition allied to auricular fibrillation and known as auricular flutter. In this condition the auricle does not contract in the usual manner. but beats ineffectively at a very rapid rate—usually about 300 times a minute. The ventricle does not, as a rule, respond to every beat of the auricle; it often responds only to every second beat, and sometimes to a varying number of beats, so that the pulse is slow and irregular.

The condition usually arises in paroxysms. The patient is conscious of a sensation which suggests that her heart is "running away" at a great rate. This is accompanied by a sense of prostration. The paroxysm may last for a few minutes or a few hours. It subsides suddenly. A sudden onset and a sudden offset—the latter being followed by one or two forcible beats—are thus distinguishing features.

This form of paroxysmal tachycardia may occur with different types of heart trouble. Its significance in pregnancy should, therefore, be considered in relation to the presence or absence of disease. When there are no signs of disease, and the patient is well and strong between the attacks, the condition is not one of much importance. This is likely to be the state of affairs in young subjects. In the elderly, beyond the child-bearing age, the arrhythmia is often associated with disease of the myocardium, and may then be of serious significance. We may note, however, that paroxysmal tachycardia is not infrequently associated with mitral stenosis in quite young people. In such cases the physician should take into consideration what I have said in connexion with that form of disease. The presence of auricular flutter naturally adds to the gravity of the condition.

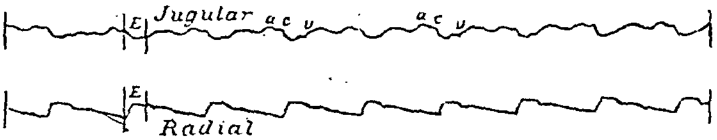

FIG. 16.—Simultaneous tracings of the jugular and radial pulses. The jugular pulse is of the auricular form.

I have had no experience of this abnormal rhythm as a complication of pregnancy. The opinion I have given is the result of the study of heart failure in connexion with auricular flutter in a large number of cases, some of which I have watched for many years.

Description of a Case of Abnormal Heart Action with Pregnancy.

I have had one case of another and rarer form of abnormal rhythm. This woman went through her pregnancy unscathed. It is partly on the inferences which I drew from her that I formed the views I have just stated.

The woman (aged 35) was pregnant with her first child. For several years previously she had suffered at times from breathlessness and irregular action of the heart. During the few weeks in which she was under my care (at the eighth month of pregnancy) the pulse was usually irregular—the degree of irregularity varying very much. When the heart was irregular the venous pulse was always large, while when the heart was regular it was barely perceptible, so much so that it was with difficulty that I could get a tracing of it (Fig. 16). Figs. 17 and 18 show the different characters of the irregularity. In Fig. 17 there are long pauses in the radial pulse (*x x x*). During these the auricular wave *a′* becomes large, an evidence that at this time the auricle and ventricle contracted together. The ventricle, however, was in systole (an extra-systole), and so the contents of the auricle could not be sent into the ventricle. They were therefore thrown back into the jugular vein. Hence the large wave *a′*. The extra-systole does not appear in the radial pulse. It is a premature contraction of the ventricle (a ventricular extra-systole). This was so small that it did not send any wave into the radial artery. Occasionally this heart would break into a series of rapid beats as shown in Figs. 19, 20, and 21. Thus there was produced a form of tachycardia whose origin is of the same nature as that of the premature ventricular beats in Figs. 17 and 18. I did not attend this patient in confinement, but I heard that she passed through it without trouble; some years after I heard that she was quite well.

THE NEUROTIC HEART.

By this term I refer to a very distinct type of heart affection in which the symptoms are due mainly to disturbances of sensation. The patients complain of pain in the left chest, usually under the breast. The pain is of a dull aching character, accompanied sometimes by "stabs." The aching varies in severity, slowly increasing and decreasing. It may last for hours; or, again, the patient may be conscious of it for days. It is not usually immediately aggravated by effort; but it may appear some hours afterwards, or, if present before, may become worse when effort is undertaken. Only occasionally is it provoked to a severe degree by effort. Attacks of great severity resembling attacks of angina pectoris sometimes arise. In these instances doctors may alarm their patients and their patients' friends by telling them that the condition is in fact angina pectoris.

It should be recognised further that these attacks of pain may come on with great severity in the absence of any apparent provoking cause.

Site of Pain and Associated Phenomena.

The distribution of the pain, while mainly confined to the left chest, may extend also into the arms and up the side of the neck. The attacks are often preceded or followed by a sense of chilliness, or cold. They are frequently accompanied by shivering resembling a rigor. There is usually present hyperalgesia of the skin and deeper tissues of the chest wall. This can be elicited by lightly pinching or pressing the left breast. In a less degree the right breast is also tender to pressure. The aching of the breast and its tenderness may lead the patient to think that there is some disease in this region.

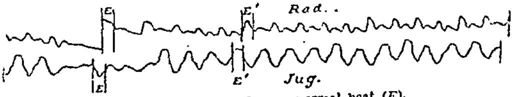

FIG. 21.—Shows only one normal beat (*E*).

These patients are liable to attacks of palpitation; and the heart's rate is sometimes unduly increased in response to effort or excitement.

When asked what sensations stop them while walking on the level, they usually reply: "A feeling of exhaustion, with a desire to sit or lie down."

Relation of the Neurotic Heart to Physical Signs.

The phenomena described above occur frequently in women; and the hearts of these women show, as a rule, no abnormal physical sign. In some, however, a systolic murmur may be detected, or an irregularity of the respiratory type or extra-systoles. The size of the heart may be slightly increased.

Those abnormal signs do not in any sense add to the gravity of the state; they are merely incidental. The condition, in short, is not due to disease of the heart—though it may be associated with disease, as, for example, mitral stenosis. It is due to some agent which increases the excitability of the whole nervous mechanism of the heart. Pregnancy can safely be undertaken by these people. It often does them a great deal of good.

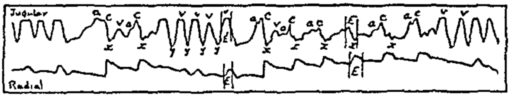

FIG. 19.—Shows a number of normal beats, with the usual waves, *a, c, v*, in the jugular, and a series of abnormal beats, small and rapid, with the waves *v* in the jugular. These abnormal beats are due to a series of independent ventricular contractions.

Conditions Predisposing to the Neurotic Heart.

There are three conditions which induce this form of cardiac weakness: (1) toxic states; (2) overwork; (3) sexual disturbances.

Toxic States.—The source of poisoning is most frequently an intestinal trouble. In every case of this sort a careful inquiry should be made into the condition of the digestive organs. The abdomen should be examined for signs of cutaneous hyperæsthesia and muscular rigidity. The presence of these latter is a sure indication of some old-standing trouble in this region. Appendicitis, gastric ulcer, adhesions around the cæcum or gall-bladder, and intestinal stasis, are among the most common conditions found. Sometimes the source of infection may be an abscess in some other part of the body, as, for example, in the antrum or at the roots of the teeth.

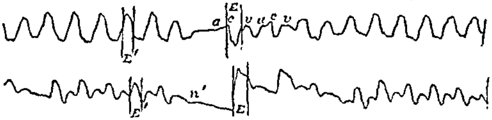

Fig. 20.—Shows two normal beats in the centre, all the rest are independent ventricular beats.

Overwork.—Women who have too long hours of labour, with little sleep, are apt to develop nervous hearts. The long nursing with disturbed nights of an ailing parent, husband, or child by a woman who has to do her housework or earn her living is an illustration in point. Any form of fatiguing work with mental worry is apt to induce the condition.

Sexual disturbances.—When no apparent cause which would account for the condition can be found, inquiry should be made into the sexual functions. For it is a fact that this type of heart is apt to be engendered in otherwise healthy young women who are married to impotent men or men who are only capable at long intervals.

One of the most extreme cases of this type which I have seen was a woman of 26, who had been married for two years to an impotent old man. Another case was a young woman who had had no intercourse with her husband, with whom she slept, because her doctor, a maiden lady of mature years, had warned her that this would be dangerous on account of her weak heart. Complete recovery followed the assumption of normal relations with her husband, and pregnancy followed.

The neurotic heart is also frequent among women, whether married or not, who indulge in masturbation. The worst case I have seen was a pretty young Jewess, whom I examined some weeks after the birth of her first baby. Not only were there present the signs of neurotic heart already described, but the heart rate was persistently increased to 130–150 beats per minute. She confessed to indulging in the habit six or eight times a day.

While dealing with this subject I may refer to another matter which bears a relation to it—the danger, or supposed danger, of coitus to women with damaged hearts. The domestic happiness of married couples is often marred by the injudicious advice of doctors who have, on account of fears as to the hearts of patients, forbidden intercourse. I have just cited an instance of the unwisdom of this advice; I have found it given so frequently that I wish to state that I know of no heart condition which should act as a deterrent when the woman feels competent. It is a matter for the woman, and not the doctor, to decide. If she finds that it comforts her, as it often does, and if she experiences afterwards nothing but a passing exhaustion, there is no ground for objection, however affected her heart may be.

CONGENITAL DEFECTS OF THE HEART AND PREGNANCY.

I have not had much experience of the complications of pregnancy by congenital defects of the heart. The opinions which I express, therefore, are based only on a knowledge of general principles. I would suggest that in doubtful cases doctors should be guided by a recognition of the state of the heart's efficiency. When the organ is enlarged, or when there is cyanosis or clubbing of the fingers, the response to effort will be so limited that it will readily be seen that pregnancy is a danger and should be avoided. When, on the other hand, the heart is normal in size, or only slightly enlarged, the response to effort good, and no cyanosis present, then, notwithstanding any physical sign—such as a murmur—which may be found, marriage and pregnancy can be allowed.

Types of Congenital Murmurs.

There are two congenital murmurs which stand out prominently. The first, and most common, is a loud, rough, systolic murmur, heard all over the heart, the area of maximal intensity of which it is difficult to determine. I do not know for certain where this murmur arises, though I lean to the view that it has its source in a small communication between the ventricles. I have met it so frequently in the young, and so rarely in the adult, that I suspect that it disappears with growth. I have, however, never been able to follow my cases long enough to see.

Patent Ductus Arteriosus.

The other murmur is due to a patent ductus arteriosus. It is a remarkable murmur, and when once recognised can always be identified easily. The tube connecting the aorta and pulmonary artery remains in these cases patent after birth. The pressure in the aorta being higher than that in the pulmonary artery, the blood passes through during the whole of the cardiac cycle and produces a continuous murmur, which is loudest at the beginning of systole, and which diminishes in loudness during diastole. It is always accompanied by a thrill over the second and third ribs on the left side. At this place the murmur is loudest.

I have only seen one case of patent ductus arteriosus in a pregnant woman. In this instance I was called into consultation to decide whether the pregnancy should be allowed to proceed and whether the patient should take chloroform. I had no hesitation in recommending that the pregnancy should be allowed to go to full term, and that chloroform should be freely given. The woman came through her confinement, and through a subsequent one, with no unfavourable incident.

I have seen a considerable number of cases of patent ductus arteriosus in the young, but only three or four in persons over 20 years of age. I have not been able to follow up my cases; but it ccurs to me that this condition also may disappear adult life.

THE MANAGEMENT OF CASES OF PREGNANCY WITH HEART DISEASE.

With an Efficient Heart.

The first duty of the physician is to decide whether or not there is any reason to expect heart failure if pregnancy occurs. The presence of abnormal signs gives no indication of the functional efficiency of the heart. That must always be estimated on the lines laid down above. If the functional efficiency is not impaired to an extent greater than that occurring in a normal pregnancy, no steps need be taken and no anxiety felt.

When, however, a woman with undoubted heart disease, such as mitral stenosis, does become pregnant the pregnancy should be allowed to continue only so long as no marked signs of heart failure are present. Such exercise as can be undertaken in perfect comfort may be permitted. But any distress, particularly breathlessness, is an indication that effort must cease.

With an Inefficient Heart.

The patient should be examined weekly for signs of heart failure, particularly for signs of œdema of the lungs as already described. If crepitations at the bases of the lungs appear, persist, and tend to increase, they may be taken as evidences of the onset of heart failure. There will also, in such cases, be present a great limitation of the field of response to effort—breathlessness being induced on slight exertion. The patient should be confined to bed or couch, and her activities reduced to a minimum. She should be encouraged to sit up or lie propped up in bed, since lying down, by restraining the movements of the ribs, tends to hamper the circulation in the bases of the lungs. At times, during the day, she should be made to breathe deeply, in order to assist the right heart in expediting the flow through the lungs.

Management of the Labour.

If heart failure is kept in check the pregnancy can be allowed to go to full time. If often happens that labour sets in, in these cases, about the seventh month; so that, as a rule, the birth is accomplished with little stress on the heart. It was my custom to give chloroform at an early stage of labour—light anæsthesia at first. My object was to restrain the "bearing down," which taxes the heart heavily. When the labour had advanced so far as to justify the use of forceps I pushed the chloroform to complete anæsthesia and delivered. In this way the straining of the last stage was avoided.

I gave chloroform freely to my midwifery cases, and never had any trouble. It is possible that "twilight sleep" may be better than chloroform, but I have no experience of it.

Indications for Shortening the Pregnancy.

When the heart failure is so extreme as to threaten life, intervention is necessary. Premature labour or miscarraige should then be induced.

Those patients in whom I induced miscarriage in the third or fifth month suffered from mitral stenosis. I had attended them in previous confinements which they had come through with difficulty—the heart failure being so extreme that it was manifest that another pregnancy would probably prove fatal. In nearly all my cases of mitral stenosis which carried to the later months premature labour set in spontaneously.

Medicinal Treatment.

Medicinal treatment by drugs of the digitalis group is not satisfactory unless auricular fibrillation is present. I have rarely found any benefit from these drugs in heart failure in mitral stenosis, so long as the rhythm remained normal. If the rate of the heart is much increased, however, digitalis may be given a trial, for sometimes it does slow the heart when the rhythm is normal. It is in auricular fibrillation that the good effects of the drug are obtained. Here heart failure is nearly always associated with a rapid rate, many of the beats being ineffective. Digitalis slows the heart, and the individual beats become strong and effective. The circulation is thus at once greatly improved. When the heart responds to digitalis, and the rate falls to 70 or 60, the drug should be suspended, and only resumed when the rate begins to increase. The quantity sufficient to keep the rate about 70 should be determined by giving and withholding the drug during a period of a few weeks. Thereafter the patient should continue for the rest of her life to take that quantity which keeps her heart beating at a moderate rate.

I have found the tincture of digitalis so satisfactory that I rarely recommend any other form. The dose should be fifteen drops four times a day, and the effect should be looked for on the fourth to the seventh day. The symptoms of overdose are nausea or vomiting, or diarrhœa, or a tight feeling of distress across the chest or a great fall in the rate. When any of these symptoms appear the drug should be stopped at once. It should be cautiously resumed when they disappear. In this way digitalis can be given without fear of untoward result.

General Management.

It is needless to dwell upon the general management of such cases. Patients must, of course, avoid conditions which throw a strain upon the heart—as, for example, mental worry, straining at stool, and digestive troubles. In regard to digestion, flatulence is often a distressing complication. It can best be avoided by taking meals in a dry state so as to compel thorough mastication. Meals should also be small in quantity and frequent.

Sleep must be obtained during the pregnancy. If it does not come naturally, then the milder hypnotics should be given, beginning with the bromides. If these fail, some of the tar products should be tried. If, in spite of these, sleeplessness persists, chloral or opium, or one of its derivatives, may be cautiously administered.

SUMMARY.

As the danger attending pregnancy in women with heart disease is the occurrence of heart failure, the physician must keep clearly before him the symptoms by which this can be recognised.

The absence of a clear conception of the nature of these symptoms has too often led to a misunderstanding of their significance. No sign manifested by the heart itself gives information as to the functional efficiency of the organ, and consequently the signs of heart failure must be looked for in other directions and more especially in those structures whose blood-supply is likely to be reduced by the weakening of the circulation.

Extreme heart failure is shown by such signs as dropsy, enlargement of the liver, œdema of the bases of the lungs, or cyanosis.

Early heart failure may be revealed by no sign when the body is at rest, and may only be discovered by distress evoked when some effort is made which the patient was wont formerly to perform in comfort.

The signs of distress, so far as women in the child-bearing period are concerned, are breathlessness and palpitation. Pain on effort may be present in certain cases of mitral stenosis and aortic disease; but, as a rule, the pain of grave heart failure is a sign which occurs much later in life.

From this it follows that no single sign shown by the heart itself, however abnormal it may seem, should be a bar to pregnancy.

Systolic murmurs, no matter in which area they are loudest, should never be a cause of anxiety in pregnancy. If they occur in hearts which show no other abnormal sign, and if the patient's response to effort is good, they should be ignored. If they are associated with other signs of heart disease, the prognosis should be based on these other signs and not on the systolic murmurs.

The same rule applies to the irregular actions of the heart due to respiratory arrhythmia and extra-systoles.

In women with easily excitable hearts, who suffer at times from pain of varying degrees of severity (the neurotic heart or the toxic heart), when the organ is normal in size, or only slightly enlarged, the heart trouble constitutes no bar to pregnancy. This applies whether systolic murmurs are present or not.

The form of heart disease which gives most occasion for anxiety in pregnant women is mitral stenosis. This usually has followed an attack of rheumatic fever. In such cases great care must be taken to differentiate between dangerous and not dangerous forms of the malady. The latter include instances in which the cicatrising process, which produces the stenosis, is stationary or is only progressing slowly. Such slow progress is shown by the character of the murmur. If there is present ten or fifteen years after the causative attack of rheumatic fever only a presystolic murmur, and if the heart's size is normal, its rate regular, and the response of the patient to effort good, then pregnancy may be undertaken with fair prospect of safety.

If, on the other hand, there is present, within a few years of the causative attack of rheumatic fever, a diastolic murmur as well as a presystolic, there will be danger. This will be particularly the case when there is evidence also of the heart muscle being damaged—i.e., enlargement of the organ and much distress on effort. When in addition to the mitral stenosis there is fibrillation of the auricle, pregnancy should be forbidden. If pregnancy has taken place, then the case should be watched; and if grave signs of heart failure occur, the pregnancy should be terminated.

In cases of aortic regurgitation, if the heart is normal in size and the response to effort is good, pregnancy may be undertaken. If, on the other hand, the ventricle is much hypertrophied, and there is a marked "Corrigan" pulse, the probability is that the heart will be so permanently impaired that it will cripple the patient severely if she gets over her confinement.

THE EPIDEMIOLOGY OF MEASLES IN A RURAL AND RESIDENTIAL AREA.[*]

BY RALPH M. F. PICKEN, M.B., CH.B.,
B.SC. GLASG., D.P.H. CAMB.,
ASSISTANT MEDICAL OFFICER, PUBLIC HEALTH DEPARTMENT, GLASGOW.

SINCE February, 1902, measles has been compulsorily notifiable in the landward portion of Renfrewshire. This area is administered by one medical officer of health, working in two districts, first and second. The first district is largely suburban, residential and industrial, with rapidly increasing population, while the second district is mainly rural and the population has increased slowly. The circumstances have therefore been fairly suitable for studying not only the influence of notification and administrative measures on measles under different conditions of environment, but also any features of the epidemiology of measles which may be peculiar to populations of low density. The period of 20 years, 1893 to 1912, has been selected for this purpose, and the writer is indebted to Dr. A. Campbell Munro, consulting county medical officer, for access to the records of these years and for guidance in their compilation.

It may be said at the outset that measles has been seriously regarded in Renfrewshire. Notification has not been an end in itself, but only the beginning of concerted preventive measures and propaganda aiming at control of the disease. The writer is satisfied, from an intimate knowledge of the administration in Renfrewshire, that every practicable means of controlling measles recognised during the period under review was applied wholeheartedly.

---

[*] Being the substance of a paper read before the Epidemiological Section of the Royal Society of Medicine on Feb. 25th, 1921.

In a previous paper[1] an effort has been made, with limited success, to demonstrate the effect of notification in Renfrewshire, by comparing the deaths from measles there and in adjoining administrative areas. So far as they went the figures quoted indicated that notification was an advantage; but the absence of the data which notification affords is an obstacle to any accurate comparison of the behaviour of measles in an area where it is not in force with one in which it is. In the course of the present inquiry any internal evidence for or against the value of notification has been sought. The main purpose, however, is to put on record the observed facts of the incidence and fatality of measles in an area of this character. No detailed information from a county area appears to be available in medical or epidemiological literature and the importance of obtaining it justifies notification, from the scientific point of view, even if no other benefit can be proved.

Periodicity.

If the monthly incidence of measles is traced in Renfrewshire throughout the years since 1891, the long and short waves, now recognised as characteristic features of the disease, are clearly seen. The long wave seems to have a period of about 20 years, although the duration of the observations is not sufficient to make this certain. The biennial period is very pronounced at the summit of the long wave, but tends to be lost in its trough. The usual spring-summer incidence occurs. The form of the waves fits fairly well Brownlee's theory of recurrent vitality of the virus at intervals of nearly, but not quite, two years.[2]

The practical point, however, is that there is fair correspondence between the behaviour of measles in the two districts and in the adjacent city of Glasgow. There is therefore fair ground for assuming that a common strain or strains of measles virus inhabit these areas and that further comparison of the statistics of measles between them is permissible.

Death-Rates.

In Table I. the mean death-rates from measles in certain periods of ten years are shown. The mean death-rate from measles in Renfrewshire has not been high in any of these periods, and it is also apparent that notification was not followed immediately by any decline. But the marked fall in both districts during the last ten years is striking in view of the fact that several years of this period were included in the summit of a long wave when a high death-rate might have been expected. It remains to be seen whether this decline is attributable to change of incidence or of fatality.

TABLE I.—*Mean Annual Death-Rates from Measles per 1000 of the Population in Certain Decennia.*

—	District I.	District II.	County.
1881–1890 ..	0·26	0·20	0·24
1893–1902 ..	0·27	0·21	0·25
1903–1912 ..	0·19	0·10	0·16

Case-Incidence.

The mean case-rates in two periods of ten years during which notification was in vogue are shown in Table II. The case-rate has declined in both districts, but to a much less extent than the death-te has fallen. The latter decline is therefore not lained by the former. The fact, however, that case-rate has fallen at all is significant in view of the fact, already mentioned, that the second period was exceptionally favourable to high incidence.

TABLE II.—*Mean Annual Incidence of Measles per 1000 of the Population.*

—	District I.	District II.	County.
1893–1902 ..	22·13	18·68	20·73
1903–1912 ..	20·24	17·04	19·21
1893–1912 ..	20·99	17·83	19·87

It would seem to be fair to give at least some of the credit to notification and preventive measures.

Fatality.

For the same periods of years the mean case mortalities are shown in Table III. A marked decline in fatality has occurred which appears to be of real significance so far as errors of chance are concerned and which accounts for the difference between the fall of the death-rate and of the case-rate. There may have been some failure of notification in the earlier years which would have the effect of exaggerating the difference of fatality and of diminishing the difference in the case-rates. In the opinion of the writer, this fallacy is not great in the Renfrewshire figures and the main feature of the period of notification, preventive measures, and propaganda has been great diminution of the fatality of measles.

TABLE III.—*Mean Fatality per 100 Cases.*

—	District I.	District II.	County.
1893–1902 ..	1·23	1·14	1·20
1903–1912 ..	0·92	0·60	0·83
1893–1912 ..	1·05	0·88	0·99
ϵ_{12}	0·16	0·21	0·12

It will be observed that the fatality of measles is lower in the rural second district than in the first, which is more densely populated. The comparison may be carried beyond the county, as in Table IV.

TABLE IV.—*Fatality per 100 Cases of Measles in Several Districts.*

Urban District, 1892–4[3]	6·1
Glasgow, 1908[4]	5·1
Edinburgh, 1880–1901	3·5
Aberdeen, 1883–1902[5]	3·3
American States, 1914[6]	1·7
Willesden[7]	1·3
Renfrewshire, *1893–1912*	1·0

Roughly, the fatality falls as the density of population diminishes. Many factors have to be considered such as age-distribution of the population, social status, higher resistance to disease of the rural child, immunity from complications and varying efficiency of administration, and some of these will be dealt with later. But some other explanation seems to be required to account for the variation of fatality not only between town and county but also of excessive fatality in isolated epidemics occurring in institutions, in armies and in "unsalted" populations many of which are recorded in literature.

As illustration, reference may be made to the behaviour of measles among the soldiers of the Highland Division at Bedford in 1914–15, a chart of which has been kindly lent to the writer by Colonel Dewar. There is no evidence that measles was more than usually fatal to the civilian population at that time, but its mortality among these susceptible Highland soldiers was 12·4 per cent. The first cases were infected from civilians and the fatality in October (8 cases) and November (79 cases) was nil and 2·53 per cent. respectively. Later, however, when other soldiers were infected from these men the fatality rose to 13·82 per cent. in December and 15·62 per cent. in January. It is not sufficient to y that the "unsalted" character of this Highland pulation was the cause of the excessive fatality; at is not the experience among similar immigrants Glasgow infected at random from the general pulation. Unhygienic conditions for the patients obably did exist but not more so in the later stages.

It is suggested that the explanation tentatively ven by Whitelegge[8] is *the correct one*—viz., that e virus of measles is intensified under circumstances hich favour rapid transmission from person to erson in a highly susceptible population. As the portunity for rapid transmission is clearly greater cities and towns than in rural districts, the fference of fatality in such areas may also be due this cause.

Incidence and Fatality According to Age.

It has been shown that the fatality of measles, respective of age, has been higher in certain urban eas than in the county of Renfrew. This might due partly to a difference in age-incidence. The oint is illustrated in Table V. If these readings are

TABLE V.—*Mean Annual Case-Rates per 1000 of the Population Living at Several Ages.*

Age.	Renfrewshire.	Aberdeen.	Glasgow (1908).

5–10	75	49	49
10–15	13	4	
15 and over ..	1·0	0·6	0·6

harted the contrast between incidence in town and ounty is well brought out. *In the county the age f attack is delayed.* Expressed otherwise, the roportion of all cases of measles which occurred at ges under 3 years (the most fatal) was 24·75 er cent. in Renfrewshire, 33·32 per cent. in Aberdeen, nd 34·50 per cent. in Glasgow. This, however, xplains only partly the difference in fatality already iscussed.

It should be noted that in Renfrewshire, as in berdeen, there is a sudden excess of incidence in he sixth and seventh years of life—i.e., at the age f entering school. This indicates the effect of chools in exposing susceptible children to measles nd justifies the attention given to this mode of ransmission in Renfrewshire, where closure of infant lasses has been regularly applied whenever departmental inquiries have shown that such classes were ikely to have been infected.

If such methods were successful they should in ourse of time delay the age-incidence of measles. able VI. has been prepared to test the result in

TABLE VI.—*Mean Annual Case-Rates per 1000 at Several Ages in Separate Decennia.*

Age.	District I.		District II.

0 and over ..	1	1	1	1

he two areas of Renfrewshire. In the first place, his table shows that the more rural district has a ower incidence at all ages under 10 years but higher above that age. In this district, too, there has been a decline in the case-rate at ages under 10 in he second decennium and a slight transference to he age period 10–15. In the first district, however, exactly the opposite movement has occurred, the younger children being more heavily attacked. The contrast may be expressed briefly in terms of the mean age of all cases under 20 years of age. In the first district the mean age fell from 5·35 years in 1893–1902 to 5·16 years in 1903–1912, while the corresponding figures for the second district were 5·94 and 6·09. The conclusion may be drawn, therefore, that in this important respect the efforts of the Health Department have failed in the first district but have had some success in the second. The further inference can be drawn that the greatly reduced fatality in Renfrewshire has not been mainly due to more favourable age-incidence of the disease in the second ten years.

The fatality of measles at various ages *of life* in different places is shown in Table VII. The general trend is similar in the four places, but *at each age* fatality in the county is much lower than in the large cities, and is approached only by that in Willesden. It is evident that whatever influences in the less densely populated areas conduce *to low* fatality are exerted equally at each age of life, and the comparatively low mortality in Renfrewshire is not entirely, or even mainly, explained by favourable age-distribution of the cases.

Influence of Social Condition.

For want of a better measure of social condition the size of house occupied has been adopted as in other similar inquiries.[4] [5] So far as incidence of the disease is concerned the population in small houses is most heavily attacked. For instance, for the years 1910, 1911, and 1912, the rates per 1000 of the population were 28 in one-apartment houses, 36 in two-apartment, 19 in three-apartment, and 13 *in houses over this size.* The records of Glasgow, which are similar, show that the difference is not entirely due to the larger population at susceptible ages in small houses, but similar census information *is not available* to confirm this in Renfrewshire.

That fatality is also connected with size of house is shown in Table VIII. The fatality falls consistently

TABLE VIII.—*Fatality per 100 Cases in Houses of Various Sizes.*

Size of house.	Renfrewshire.	Aberdeen.	Glasgow.
1 apartment ..	1·85	6·8	9·2
2 apartments ..	1·24	3·0	4·6
3 apartments ..	0·69	1·8	2·5
4 apartments and over	0·31	0·9	1·5

as the size of house increases. In Scotland, however, the *occupants* of one- and of two-apartment houses belong practically to the same social grade, and it is probable that the heavier mortality in one-apartment houses is mainly due to the larger proportion of young children among the occupants. This view is strengthened by examination of the fatality-rates among children in Renfrewshire under 3 years of age, which are 3·7 per cent. in one-apartment, 3·7 per cent. in two-apartment, 2·5 per cent. in three-apartment, and 1·1 per cent. in larger houses. The general rule, however, holds good even at these ages that fatality diminishes as social station improves.

Table VIII. also completes the demonstration that Renfrewshire's low fatality is not due to better social conditions of the patients, just as it has been shown not to depend on favourable age-distribution.

The Administrative Control of Measles.

Any measures for this purpose must have regard to the channels of infection. Children are infected in their homes or at school or at random. The fact is that most children of school age, especially in rural districts, are infected at school, and it is through the school that any measures to control measles have usually been applied.

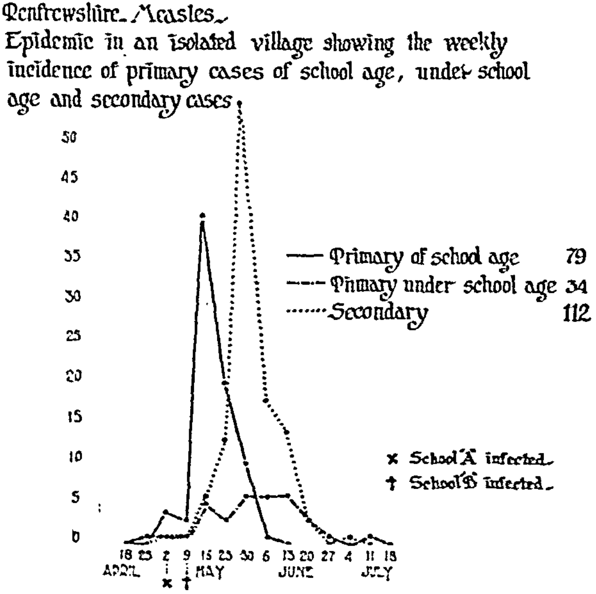
The effect in Renfrewshire of domiciliary and of extra-domiciliary infection on the age-distribution of cases is shown in Table IX. Whereas, only 34·6 per cent. of the primary cases are under 5 years of age, 65·9 per cent. of the secondary cases occur at these ages—i.e., before entering school, and the sudden aggravation of incidence among primary cases in the sixth and seventh years is further evidence of the influence of schools.

TABLE IX. — *Age-Distribution of 19,567 Cases, Showing Primary Cases in Families Separately from Secondary Cases.*

Age in years.	Primary.	Secondary.	Age in years.	Primary.	Secondary.
–1 ..	334	513	–7 ..	2058	419
–2 ..	738	1029	–8 ..	1505	306
–3 ..	900	1158	–9 ..	955	300
–4 ..	1017	1181	–10 ..	536	212
–5 ..	1180	1086	10 and over ..	1067	642
–6 ..	1740	691	Total ..	12,030	7537

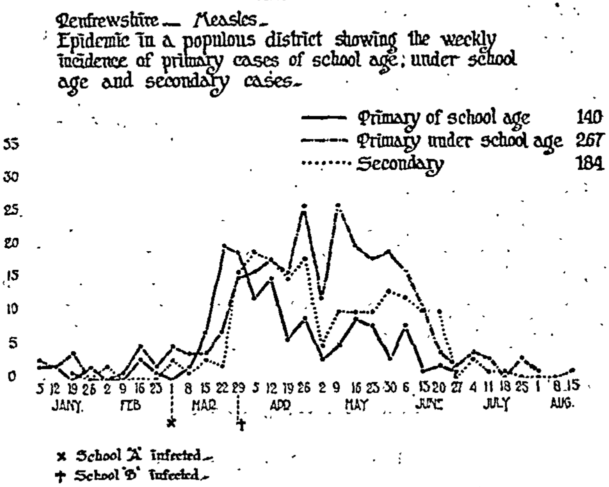
This influence is also illustrated by Charts 1 and 2, which show for two typical districts the course of a measles epidemic as it involves the school population and the children under school age. Chart 1 shows the course of an epidemic as it affected primary cases among school children, other primary cases and secondary cases in a relatively isolated village. In the first three weeks most of the cases were primary cases of school age, while secondary cases formed the bulk of those sickening in the last four weeks. Primary cases under school age formed a small proportion at any time. The epidemic burned itself out in eight weeks. Only half the cases were infected outside of their homes, and less than one-third of these were under school age. This form of epidemic is characteristic of the incidence of measles in isolated villages.

CHART 1.



In the other epidemic (Chart 2) a populous area on the outskirts of Glasgow was involved. Sporadic cases were occurring until the infant class of a school was infected on March 4th, an outburst of school primary cases following a fortnight later. In another fortnight a crop of secondary cases occurred and, coincidently, the incidence of primary cases under school age increased. The fall of school primary cases was delayed by infection of a second school and the curve of secondary cases followed more or less the same course; but the primary cases under school age continued to occur in increasing numbers and formed the bulk of the latter half of the epidemic. More than two-thirds of the cases were primary and two-thirds of these were under school age. This chart is typical of the course of measles in populous places.

CHART 2.



Clearly, it would be difficult to control an epidemic of the latter type by efforts directed at the school. Random infection plays too large a part. On the other hand, the epidemic traced in Chart 1 indicates that control through schools may be possible. Dr. Campbell Munro[9] and others have cited many instances in which they were satisfied that school closure had been effective in practice, and the statistics as to mean age, &c., quoted above suggest that such measures have been of value in the second district of Renfrewshire, where small isolated communities predominate. The results in Renfrewshire, however, which probably represent the best that can be obtained by school closure, indicate only partial success. In any case such measures can only indirectly protect the young children who constitute the bulk of the secondary cases and among whom the fatality is high.

The method suggested by Brownlee[10] of transferring exposed susceptible school children from homes where there are younger susceptible children aims at a solution of this problem. It presents serious administrative difficulties and would probably fail in populous districts, but an area such as the second district of Renfrewshire would be a suitable field for an experimental trial of the method.

Hospital treatment and home nursing can provide effectively for only a limited proportion of the cases lying ill at any one time during an explosive epidemic. In any case such methods can have little or no effect on the incidence and it has not been proved that they diminish the fatality to a greater extent than continuous propaganda as practised in Renfrewshire.

Conclusions.

1. Notification of measles has been justified in Renfrewshire, not only by the epidemiological information it has furnished, but also by its effect on mortality from the disease.

2. It has not materially affected the case-incidence in the more populous districts, but there is evidence that the rural districts have benefited also in this respect.

3. Apart from any administrative measures, age-incidence, or social conditions, there are factors rendering measles a much less fatal disease in rural than in urban areas.

THE NECESSITY OF NOTIFICATION OF MEASLES.

By REGINALD DUDFIELD, O.B.E., M.A., M.B.

WITH our present knowledge of measles the only uses to which we can put any information of the occurrence of the disease are: (1) The segregation of susceptible contacts—the "O.M.'s"—attending the public elementary schools; and (2) the bringing into operation of any provision for the nursing of patients in their homes, made by the local authorities. I do not wish to absolutely exclude such ancillary procedure as removal to hospital, but I doubt whether such removal should not be considered as part of the nursing scheme referred to above rather than as a method of preventing the spread of infection. I pass over the desirableness of having complete information of the prevalence of the disease for the study of its epidemiology, &c.

It is customary to decry compulsory notification of measles partly on the score of expense and partly because it is alleged that notification in the past has failed to yield any useful results. The experience in Aberdeen is the stock argument brought forward against proposals to make the disease notifiable.

No one will question the importance of early information of cases reaching the officers responsible for dealing with the disease. I use the phrase "dealing with" rather than "controlling," but I do not wish it to be understood that I regard the disease as beyond control. I feel fairly confident that some method of more or less complete control will ultimately be evolved, but that question I do not propose to take up on this occasion. If compulsory notification be ruled out the only source of information on which any reliance can be placed is that obtainable through the schools. I shall show that that channel is unsatisfactory for two reasons.[1] In the first place, the cases reported form only a fraction of the full total, and in the second, the interval which occurs between the onset of the disease and the forwarding of the report of the case, is, with the present machinery, so long that the success of segregation is jeopardised and the efficiency of any provision of nursing seriously impaired. As regards segregation, I am assuming that it must be put into operation at the latest eight days after the onset of original case, or, having regard to the uncertainty of the first day of infectivity, four days after the appearance of the rash. As to nursing, I think that any delay may be dangerous, but for argument's sake I will assume that an average delay not exceeding six days from the onset, or two days after the appearance of the rash, may be hazarded with a certain degree of impunity.

Dr. W. H. Hamer advocates school reports in preference to notification, and the Ministry of Health took the same line in the circular letter of December, 1919. I have tried both systems and have come to the conclusion that notification is the only reliable source of information. Careful records of the prevalence of the disease in Paddington have been kept since 1903—from 1903 to March, 1914—based on school reports ("Form 81") and from the latter date on notification.

Notification was initiated in Paddington in March, 1914, by an Order[2] made by the Borough Council under Section 56 of the Public Health (London) Act, 1891, the Order being in the first instance for three months, but subsequently made without time limit. When the Measles Regulations of 1915 came into operation the Council's Order was rescinded (February, 1916) at the request of the Local Government Board. In December, 1919, the Ministry of Health announced that the Measles Regulations, 1915, would be rescinded as from January, 1920. The Council thereupon obtained from the Ministry a new set of Regulations, the "Measles (Paddington) Regulations, 1920." Nominally there was no interruption in notification, actually the announcement in the daily and medical papers of the rescission of the Measles Regulations, 1915, caused considerable uncertainty in the mind of the profession, and a good deal of explanatory correspondence was necessary to clear up the ambiguity.

The local records of the disease cover, therefore, 18 years, those for 11 years (1903-13) being based on school reports, and those for the remaining seven years (1914-20) on notification—both sources of information being supplemented by inquiries made by the women inspectors. During the 18 years 27,280 cases of measles have been known to me, or an average of 1525 per annum. During the first period—the 11 years of school reports—the cases totalled 12,567, with an average of 1142 per annum. For the other seven years—notification (not uniformly complete) in force—the total number of cases was 14,713 and the yearly average 2102, or 960 more than in the former period. Such figures suggest that something over 40 per cent. of the cases were not reported. I say "suggest" because I have reason to think that the disease was more prevalent during 1914-20 than in 1903-13.

A comparison of the rates of fatality recorded during the two periods is even more "suggestive" of the deficiencies of school reports. The deaths during 1903-13 averaged 43 per annum, those during 1914-20, 40, and the fatalities for the two periods were 3·73 and 1·91 per cent. In other words, the average fatality during the years of school reports was 51 per cent. above that for the notification years. So far as I am aware there is no reason for assuming that the fatality during the former period was higher than that during the latter. I incline to think that it was, on the whole, lower. In any case fatalities of 2·37, 2·68, and 2·15 per cent. were observed in 1915, 1917, and 1918.

Without giving a definite opinion as to the measure of the defect, I think it will be agreed that reliance on school reports entails a serious deficiency in the number of cases reported. Having regard to the fact that a double system of reporting—viz., by school teachers and by doctors—has been in force since 1914, it will be of interest to see to what extent the school teachers' reports precede the doctors'. During the seven years in 1522 instances—11·0 per cent. of all known cases—the school reports were received before the notification certificates. The highest percentage in any year was 18·8 (1914, notification in vogue for some months only) and the lowest 7·7 (1917). In 1920 the percentage rose to 14·4, but in that year notification was rendered less complete owing to the rescission of the Measles Regulations, 1915.

---

[1] There is one incurable defect associated with a system based on school reports. I refer to the intervention of the holidays, when naturally, all such reports cease.

[2] The Order made in 1914 required all cases of measles to be notified, excluding German measles. The Measles Regulations, 1915, called for notification of first cases only of measles and German measles, while the local Regulations, 1920, cover all cases of both diseases. I have limited my statistics to measles (*Morbilli*).

Before considering the question of delay attaching to school reports it will be well to touch on that of the completeness of compulsory notification. It is frequently argued that many cases of measles receive no more than domestic treatment and that in consequence, even with compulsory notification, a fairly large number of cases will never be reported. In part that difficulty is met by the fact that parents are required to notify cases as well as medical practitioners. If a case be traced in which no doctor has been in attendance, and for which no notification has been received from the parent, a letter is addressed to the parent calling attention to the omission and warning him of the penalty to which he has rendered himself liable.

During 1920, out of 1946 known cases there were 141 (or 7·2 per cent.) which were not medically certified, being reported by school teachers only.[3] I will not venture to say that those 141 cases give the full measure of failure of notification, but I can say that I believe that very few primary cases escaped my knowledge. The 141 instances referred to above have been analysed to show the intervals between the date of onset of the disease—determined by the appearance of the rash—and the date on which the school report was received. The results are shown in the appended table. As a basis of comparison with compulsory notification the same facts have been taken out for 346 cases occurring in the poorest localities in the borough, where action must be prompt to be effectual.

Days after Appearance of Rash.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	17	18	19	21
		(5)	(6)	(7)	(8)	(9)	(10)	(11)	(12)	(13)	(14)	(15)	(16)	(17)	(18)	(21)	(22)	(23)	(25)
School forms ..	—	19	27	26	13	11*	8†	8	3	4	4	6	2	1	4	2	2	1	—
Notification ..	10	92	125	67	28	14*	7†	1	—	2	—	—	—	—	—	—	—	—	1

Totals: School forms, 141; notification, 347.

* Limit for segregation of "O.M.'s." † Limit for nursing scheme.

As regards segregation of contacts, a delay extending beyond the fourth day subsequent to the appearance of the rash has been postulated as rendering segregation useless. If that be granted, it means that 56 out of the 141 cases—39·7 per cent.—were reported too late to allow the "first crop" of secondary cases to be excluded from school before they became infectious. Compare that proportion with the proportion of notified cases. In the latter group only 24 (6·9 per cent.) were reported too late, even with the inclusion of the odd case of 21 days.[4] For the school cases the average interval for the 141 cases was 4·31 days from the appearance of the rash, or over eight days from first infectivity, whereas for the notified cases the intervals were—from rash 2·3, or from first infectivity just over six days.

As regards nursing, a delay of two days after the rash has been allowed for argument's sake. Such limit includes only 46 (32·6 per cent.) of the school cases, and 227 (65·6 per cent.) of the notified cases. Comment appears to be unnecessary.

---

[3] *These 141 cases were primary cases. There were in addition 341 secondary cases which were not medically certified, but were reported by the women inspectors.*

[4] As a matter of fact, the three cases reported 7, 9, and 21 days after onset were accidents, the practitioners concerned usually reporting very promptly.

Industrial Welfare Society.—A conference on the organisation of industrial canteens will be held to-day (Friday), at Caxton Hall, Westminster. In the morning an address will be given by Mr. Arthur Agar, late Chief Organising Inspector of Munitions Canteens, and in the afternoon a discussion will be opened by Sir Francis Towle.

A FURTHER CONSIDERATION OF SANATORIUM CONTROLS.

By E. WARD, M.D. Camb., F.R.C.S. Eng.,
TUBERCULOSIS OFFICER, SOUTH DEVON.

The discussion following my recent paper, a Controlled Study of Sanatorium Results, calls for some reply. So far nothing has appeared in the correspondence which calls for a reconsideration of my views. Single cases prove nothing; any of the numerous special treatments for tuberculosis advocated in the past have been supported by cases, most of them genuine, which seem to uphold the originator's contentions.

Dr. Campbell Thompson tells us, "Other treatment of pulmonary tuberculosis stands to sanatorium treatment somewhat in the relation that moonlight does to sunlight." Allowing for poetic licence (sunlight is to moonlight as 600,000 to 1) he means presumably that sanatorium treatment must be regarded as several times more efficient than other forms of treatment. Dr. Noel Bardswell, investigating the mortality of pulmonary tuberculosis after treatment at Midhurst, finds that patients at the average age of 33, discharged from Midhurst with the disease "arrested," have the same expectation in life as an unselected individual aged 60, while patients at the same average age, discharged "much improved," have the same expectation as an unselected individual aged 74. This, says Dr. Thompson, is sunlight. It can hardly be denied that the treatment at Midhurst is as good as any in the country. Moreover, their patients are drawn from an intelligent class, and both come from, and return to, far better surroundings than the ordinary working-class sanatorium patient. We are driven, then, to conclude on Dr. Thompson's basis, that patients at an average age of 33 who have not been to a sanatorium, but whose disease appears "arrested," will have the same expectation in life as an ordinary individual aged 130, and a patient aged 33 similarly "much improved" the same as an ordinary individual aged 212. An absurdity which suggests that Dr. Thompson's conclusion may be erroneous.

The only way to get light on this difficult matter is to control results from sanatorium treatment by other results, and this is what I have attempted to do. One critic accuses me of taking a gloomy view of tuberculosis, but I *cannot accept this.* If sanatorium results, as represented by the Midhurst figures, show the best that can be done for patients, and those that do not go there fare much worse, as my critics believe, the prospect for sufferers is gloomy indeed; but if our sanatorium results can be greatly improved by altered methods, as I suggest, and if patients not going there may yet do quite well, the outlook is surely less gloomy.

Methods of Investigation.

I am anxious not to overcall. My inquiry dealt with only one district, with patients drawn from the working classes, sent to sanatoriums for an average period of three and three-quarter months, and treated by modern methods. It referred not to immediate results, but to those observed at the end of two or four years. I have no ground for contradicting those who say that three months is an insufficient period, and that no results can be expected in so short a time, but this is the standard period of sanatorium treatment in this country for working-class patients. Dr. E. E. Prest may be quite right in stating that modified methods give better results. I do know that he is a progressive thinker in these matters and would not hesitate to adopt any improvement which occurred to him, no matter how unconventional it might be. But compared with the reports of various sanatoriums published from time to time, my sanatorium results, without the controls, seem favourable.

Dr. Thompson says, "Dr. Ward writes sarcastically that if patients were kept at the institutions for a year or more we should have our authorities urging for a period of three or five years instead of one." Yet Dr. J. Crocket the following week says exactly this, "Many patients require three years, and not three months." My figures do not disprove this, but if sanatorium treatment is to be used, and it becomes a question of three years' treatment to achieve arrest, it is certain that considerably under 10 per cent. of the class of patient here considered would submit to it, possibly under 1 per cent., quite apart from the enormous expense involved. So we are driven to Dr. Noy Scott's proposition, who "cannot help thinking that if much of the money which has been spent on sanatoriums had been used to enforce by-laws regarding fresh air and sunlight in *cottages* we should have had better results." I should prefer to utilise modified sanatoriums partly as hospitals and partly as preventoriums. There is a great deal in the suggestion made in THE LANCET editorial of April 16th, "We would venture the prophecy that sanatorium treatment will more and more develop on the lines of prevention in the young, *than 'cure'* in the adult."

To classify patients according to the intensity of the disease rather than the extent would be desirable; for some time I considered how it might be done, but came to the conclusion that it was not possible in my series, for only observation in hospital could enable such a classification to be made. This does not tell unduly against the sanatorium, as acute and pyrexial cases were not sent there. Moreover, nearly all the published results of sanatorium treatment divide cases, with various modifications, as in my paper, into first, second, or third stages.

Dr. Thompson complains that I have included in the sanatorium series patients who had been there just over a month. But the line had to be drawn somewhere, and after consideration I drew it at a month. Had I drawn the line at a full three months' treatment, no doubt the accusation would have been made that among the controls many were included who *had all the* educational value of sanatorium treatment, though their stay was comparatively short. Dr. Crocket cites a case in whom the disease became arrested only after three years' sanatorium treatment. Dr. Thompson also cites a case of arrest of advanced disease after three years' treatment. But a single case in this regard is of no value. Most *practitioners* of experience could cite parallel cases of patients who recovered after years of invalidism, and yet who never went to a sanatorium. The same may be said for all special methods of treating tuberculosis, orthodox and heterodox (although the advocates of these ask, as the sanatorium supporters, for early cases).

To go further afield, I know *of one* case of extensive pulmonary disease, accompanied by laryngeal tuberculosis, who, after sanatorium treatment for a year or more in different institutions was still quite unfit, and yet, after an interval of another year, recovered, and undertook an important municipal post during the war. The patient attributed his recovery to the abandonment of all *medical treatment* and the adoption of Christian Science. Then there is the case, much boomed a few years ago, of a girl who became "delicate" at 12, was nine months in a sanatorium at 15, after which she continued an invalid, tubercle bacilli being present in the sputum. From 19 to 22 she was for the most part confined to bed, and then "miraculously" recovered. I know two of the doctors who attended this girl, and who, while not ready to acknowledge the "miracle," admit that she recovered and was able to resume an active life after years of apparently hopeless illness. I have also read a paper published in the 1860's which quoted some remarkable arrests of tuberculosis attributed by the author to the administration of cod-liver oil. I would also like to quote from my original paper, "Undeniably a few cases are definitely and permanently improved by sanatorium treatment, and it is worth considering if this number can be increased by improved methods."

Dr. Thompson asks how it is possible *to tell that* patients treated at a sanatorium often lose ground so rapidly, that after two years they have fallen below the level they would have reached if they had never been there. This conclusion was reached by comparing cases that seemed clinically similar, some of whom went to a sanatorium and some did not; also by comparing the results where one member of a tuberculous family was sent to a sanatorium and another not. It is not claimed that this is a mathematical proof, but one cannot get much nearer to a proof when dealing with human material. When writing towards the end of the paper "a patient at a sanatorium would stay indefinitely, the longer the better," I referred mainly to the use of sanatoriums as hospitals for isolation purposes, and presumed also that an attempt to improve sanatorium methods would be made.

Major and Minor Tuberculosis.

An editorial article in THE LANCET of April 16th rightly considers that before discussing the subject it is necessary to define what we mean by sanatorium treatment. Perhaps even this should be preceded by defining what we mean by pulmonary tuberculosis.

Dr. Crocket considers that my controls were "a *doubtful collection.*" This may well be true, but so also then were the cases sent by me to a sanatorium. In my cases all were included that might arguably be considered suitable for a sanatorium, and for this reason I added a large number of Stage III. cases to the controls, whom I, personally, would never have sent to a sanatorium. I have always tried to send *early cases* to a sanatorium, which is what they ask for; this was so even when in practice, before the days of tuberculosis officers. The medical superintendent at our county sanatorium then considered the cases I sent were what he wanted; so much so that although there was the usual pressure on his beds he would ring me up when a vacancy was *about to occur*, and ask if I had anyone to fill it, adding that he gave me first chance, because I never sent anyone unsuitable.

The last paragraph of Dr. Crocket's letter suggests that he regards as definitely tuberculous only the patients who do not improve with treatment other than at a sanatorium. If this reading is correct it is not far removed *from the old* conception of "consumption" as a disease which never recovered, and that, if a patient did recover, the diagnosis was wrong, and he had never had consumption. Dr. Thompson also complains that I am suggesting tuberculosis is "a comparatively benign disease," although, later in his letter he paradoxically accuses me of pessimism, because *I have observed* that patients may get well without going to a sanatorium. There must be some misconception here. Pathological evidence indicates such a very wide prevalence of healed, or partially healed tuberculosis in patients dying from other causes, that the pathologist whose lectures I once attended spoke of tuberculosis as "one of *the most* curable of all diseases," and a letter which recently appeared in the press from a distinguished bacteriologist suggested, reasonably it seemed, that as the immunity caused by inoculation to tuberculosis was so short-lived the reason of such a large amount of apparently acquired immunity among the population at large was due to the presence of *a slightly active* lesion. In my paper I pointed out the difficulties arising from the common existence of pathological as opposed to clinical tuberculosis. The use of the words minor and major tuberculosis for these conditions seems more suitable, for it is almost certain that the great majority of patients showing pathological tuberculosis did, at some *time or* other, when the disease was active, suffer from a few symptoms. They were easily tired perhaps, or got "run down" or thin, or developed an obstinate "stomach" cough, and at that time it is quite likely there were a few physical signs to be detected, such as dullness at one apex, a few crepitations, and diminished breath sounds. Such cases are met with often enough when examining contacts in the home, and present a serious difficulty in attempting any such comparison as I have made. Most of these get well within a short time (I have known this happen within a month or two even when tubercle bacilli were found in the sputum on the only occasion when any was procurable), but some go on to major tuberculosis, and this is where the preventorium should prove beneficial. Many such I have sent to a sanatorium. A comparison of Stage II. cases alone in each series seemed to me enough to eliminate minor cases. When collecting cases I had no bias beyond a moderate belief in the efficacy of sanatoriums, and did not know whither the inquiry would lead.

In considering tuberculosis to-day one great difficulty is that the majority of those who give thought to the subject have been narcotised by sanatoriums.

Treatment other than at a Sanatorium.

Dr. Crocket suggests that if I am right "the best thing that can be done for tuberculous patients would be to leave them alone." If he will make this read "for many tuberculous patients" it is certainly correct. A number of patients do well if reassured and left alone under the normalising influence of their daily work, with possibly occasional observation by the physician, so that other methods may be tried if progress seems unsatisfactory. Minor tuberculosis in private practice is usually treated in this way, and on the whole successfully, with or without the addition of some medicine which enables the doctor to maintain the observation. When tuberculosis becomes more manifest, and has been definitely mentioned to the patient, "advice only" does not for a moment imply no treatment at all. It is here, indeed, that the skill and individuality of a fadless practitioner can be exercised most efficiently. First, to read between the lines of the patient's history, then to put right what is wrong in his daily life. To substitute, for instance, something restful for a too vigorous recreation, or too many public activities in the patient's spare time; or to modify the despairing desire for a short life and a merry one, which so often arises when a patient, especially a young patient, does not feel as well as he did, and suspects that something serious is the matter. And in many patients the weekly encouragement by their doctor is a most important aid to recovery.

Conclusions.

I still hold the views set forth in the paper read on Jan. 31st last. On the one hand I have received severe criticism from some of those engaged in tuberculosis work, but on the other hand several practitioners of experience have informed me that they agree whole-heartedly with my remarks; and the experienced practitioner is generally able to pass very sound judgments on treatment other than his own. The most hopeful means that I can see of dealing with the tuberculosis problem is by adequate isolation of infective cases. This necessitates hospitals, of which there is a shortage, and the introduction of appropriate legal measures, of which there seems no prospect. The preventorium, especially for children, also seems promising, and by all means let us try to improve and coördinate the present sanatorium methods. A committee of experts to visit sanatoriums with the object of devising better treatment, and of standardising our methods, as advocated by the Association of Medical Superintendents, would be admirable if the members are not chosen solely from medical superintendents; it should include a general practitioner, a surgeon (for sanatorium treatment is often beneficial to rgical cases), and an intelligent layman.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

A CASE OF DELAYED TETANUS TREATED WITH LARGE DOSES OF ANTI-TETANIC SERUM.

BY S. E. DENYER, C.M.G., M.A., M.D., B.C. CAMB., F.R.C.S. ENG., D.P.H. LOND.,
ACTING HON. PHYSICIAN, HULL ROYAL INFIRMARY; LATE EXAMINER IN ANATOMY, CAMBRIDGE UNIVERSITY, ETC.

THE following case is of sufficient interest to merit permanent record:—

A. B., 24 years, was admitted on April 28th, 1917, to Hull Royal Infirmary, under my care, with inability to open his mouth. He had been wounded five months before and had sustained a gunshot wound of the face, right arm, and right leg. His right eye had been excised and anti-tetanic serum was stated to have been administered on the same day, and again a few days later. After this he appeared to go on well, and the wounds healed up. On April 24th he found he could not open his mouth properly, and he had attacks of shivering. On the 25th he consulted Dr. Soutter, of Hedon, who diagnosed tetanus and sent him into the Hull Royal Infirmary.

On admission he was able to walk into the ward. There was marked trismus, he being unable to open his mouth more than one-eighth of an inch; back rigid, neck stiff, and any endeavour to sit up brought on a severe spasm of the jaw. No headache, temperature normal, pulse-rate 100; he complained of a cough and some pain over insertion of diaphragm. Slept well; no mental symptoms, tremors, or Kernig's sign, but marked increase of the reflexes. No local pain in the wounds which were healed, but a local increase of reflex excitability in the muscles of the face. No sore-throat or difficulty in swallowing. There was considerable general muscular rigidity.

Treatment.

The patient was put on fluids ad lib. Milk, beef-tea, &c., and treated with intrathecal, intramuscular, and subcutaneous injections of anti-tetanic serum.

The following amounts were given: the numbers represent hundreds of units:—

Date in 1917.	Intra-thecal.	Intra-muscular.	Sub-cutaneous.	Date in 1917.	Intra-thecal.	Intra-muscular.	Sub-cutaneous.
28/4	30	15	—	9	—	160	—
29	—	15	—	10	—	160	—
30	30	15	—	11	—	80	—
1/5	160	15	—	12	—	80	—
2	—	80	15	13	—	30	—
3	160	160	80	14	—	30	—
4	160	80	—	15	—	80	—
5	—	80	30	16	—	80	—
6	160	80	30				
7	—	80	80	17/5*	—	—	—
8	—	80	—	18	—	30	—

* No serum administered on this day.

Total of units given, 2365 hundreds, or 236,500 units.

The intrathecal injections were in every case given under chloroform, and owing to the patient's weakness after chloroform it was considered advisable when possible to miss a day. Twenty-one injections of ¼ grain of morphia were given during the period for the first few days, two a day being given. On May 5th a serum rash appeared. On the 8th he was able to move himself much more in bed and was able to read; on the 9th he was able to sit up in bed and had fish for dinner, but could not open his jaw very widely. On May 16th he could open the mouth quite well, but not to its full extent. There was no stiffness in the muscles of the face. I saw this patient in robust health a year ago, three years after the attack of tetanus.

Remarks.

This case illustrates the value of large doses of serum in the treatment of tetanus. I should point out that the serum was given intrathecally, after lumbar puncture, an equal quantity of cerebrospinal fluid having been drawn off. This method acts on the nerve cells in a shorter time than the intramuscular injection (it is stated in about 12 hours), the intramuscular injection taking 24 hours and the subcutaneous a still longer time. Intravenous injection was not given on account of the danger of possible anaphylaxis. Medical Abstracts, Vol. I., p. 116, quoting Richet, Brodin and Saint-Girons, "On the immunising action which chloride of sodium manifests on the determining anaphylactic dose," states that if nine parts of saline 0·8 % are mixed with one part of plasma, the anaphylactic reaction does not occur. In the above case there was no sign of anaphylaxis, although a large amount of serum was given by subcutaneous, intramuscular, and intrathecal routes.

It is, I believe, difficult at the present time to obtain the highly concentrated serum suitable for intrathecal injection. In a case of tetanus which came under my care a few months ago, I was unable to obtain the highly concentrated serum; the more dilute is not nearly so efficient for intrathecal injection, as only a small quantity can be injected into the spinal theca.

A CASE OF

DIVERTICULITIS WITH METASTATIC SUPPURATION.

By W. E. FOGGIE, M.D. EDIN.,
EXTRA PHYSICIAN, DUNDEE ROYAL INFIRMARY; LECTURER ON CLINICAL MEDICINE, ST. ANDREWS UNIVERSITY.

THE following is a record of the clinical history and post-mortem examination of a case of diverticulitis in which the rare sequela of metastatic suppuration was present.

C. C., a woman aged 80, was admitted to hospital on August 20th, 1920, with a left-sided paralysis of 14 days' duration.

Family and Personal History.—Her father died of a "stroke," and her mother of pulmonary tubercle. Her only brother and her only sister died in infancy. She was a nurse for 30 years, mostly with private patients, and latterly she has been a prison wardress. Her home conditions are satisfactory. Erysipelas, chronic bronchitis, and neuritis make up her past ailments.

Present Illness.—She has had threatenings of "shocks" for a year or two and has on several occasions fallen down. Two weeks before admission she fell down and was unable to get up. She did not lose consciousness, but was confused. She was unable to stand, and could not move her left arm or her left leg. She has remained in this condition until her removal to hospital.

Condition.—Patient is a very big, heavy, fat woman. She looks aged and helpless as she lies in bed. Her memory is poor unless she happens to be talking about old times. Her chief complaints have reference to pain in her paralysed left leg and left arm. The pains are situated in back of leg and thigh; in upper limb they are in the arm and pass into the neck. Sensation to light touch appears diminished over left side. Left arm is held rigidly in a flexed position close to the chest; there is slight power of movement in the fingers and at the elbow, and also in the leg, but any movement is attended by severe pain. The tongue on protrusion is deviated to the left. Muscles flaccid in the left lower extremity, but rigid in the upper. No obvious wasting. Examination of reflexes on left side shows knee-jerk difficult to elicit, a Babinski, and absence of an ankle clonus; left abdominal reflex is present; supinator and biceps reflexes are exaggerated. Pulse 72, regular; artery wall thickened. Slight enlargement of heart to left; mitral first sound long; respiratory system appears normal. Tongue coated; bowels constipated. Urine, which has a sp. gr. of 1010, is acid, dull-straw in colour, and contains albumin.

Progress of Case.—Patient showed no sign of improvement after admission. The condition was apparently stationary for the first week, but thereafter it got worse from day to day. The pains increased, a cough developed, the patient became sleepless, and the heart failed. The end came at the beginning of the fourth week with increasing weakness, Cheyne-Stokes breathing, and mild delirium. The temperature remained subnormal throughout. The pulse quickened a little after the first week, but was generally only between 100 and 108. The respirations remained quite quiet until the last day or two of life. After one week incontinence of urine set in and remained during the rest of her life. Constipation continued until a day or two before death. The patient died on Sept. 13th. The clinical diagnosis was cerebral hæmorrhage.

Post-Mortem Report.

The post-mortem report by Prof. L. R. Sutherland was as follows.

The body is markedly obese. The layer of adipose tissue over the abdomen measures fully 1¼ inches in depth. The heart is soft and fatty, showing infiltration of the wall of the right ventricle. The aorta is atheromatous. The left lung shows several considerable abscesses having the character of embolic abscesses surrounded by condensed lung tissue The pleura covering several of these is necrosed. Branches of the pulmonary artery contain slightly adherent thrombus. The spleen, kidneys, and liver present nothing noteworthy. The sigmoid flexure, which has large appendices epiploicæ, is the seat of multiple false diverticula. From one of these seen before disturbing the part a small amount of pus exuded. The mucous membrane of the lower bowel generally is hyperæmic. In the brain there is œdema of the soft membranes. The vessels at the base are atheromatous. On the right side in the region of the external capsule there is an area of evidently purulent softening. This is an ill-defined abscess measuring roughly 1¼ inches antero-posteriorly by ¾ inch tranversely. It is regarded as an embolic abscess. These is no evidence of hæmorrhage.

Summary.—Multiple diverticula in large intestine—suppurative diverticulitis. Embolic abscesses in lung (thrombosis in pulmonary artery). Embolic abscess in brain, &c.

Commentary.

The entry of diverticulitis into general recognition as a clinical entity dates from the review of the subject by Telling[1] in 1908, when after an analysis of 105 cases the main lines of its pathology and its clinical manifestations were laid down. The disease received much attention after this more especially from surgeons, so that Lockhart-Mummery, in his treatise on diseases of the colon,[3] is able to give a detailed account of the condition and of its surgical treatment. In 1917 Telling and Gruner,[2] from a study based on 324 cases, were able to amplify and give more definition to their previous picture on both its pathological and clinical sides. Lastly, in 1920, in a discussion at the Royal Academy of Medicine,[4] opinion was focussed from many sides on the whole subject especially as regards its ætiology, diagnosis by X ray, and surgical treatment.

It is now recognised that the condition occurs generally in those at least of middle age, frequently in the obese, and often where there is a history of constipation with the added factor of increased pressure inside the bowel. The main site is the sigmoid flexure. The diverticula, generally multiple, allow the retention of fæcal material which goes on to the formation of concretions. With subsequent bacterial invasion there results a diverticulitis which may lead on to perforation, or to adhesion to neighbouring organs—e.g., to the bladder, or to tumour formation and possible stricture. In short, the diverticulitis in an acute or in a chronic form has to be reckoned with in the diagnosis of the various surgical or gynæcological conditions occurring in the left lower quadrant of the abdomen. The present case is on a somewhat different footing. It happened in a weak old woman, and the diverticulitis had not proceeded so far as to develop those secondary results which bring the disease within the likely range of clinical recognition. It is sometimes possible at this stage of the disease to demonstrate the presence of the diverticula by the use of X ray with bismuth meals.

In his review of 1908 Telling could only find one example of metastatic suppuration, that of Mackie Whyte,[5] who found in a patient ill with rigors and pyrexia, multiple abscesses of the liver, secondary to a diverticulitis in a cavity the size of a thrush's egg in the sigmoid flexure. In p. 191 of his monograph of 1917 Telling still says "so far only one example of this (i.e., metastatic suppuration) has been recorded." I have not been able to find any other case, so that the above appears to be the second recorded one. It is regretted that the abscesses in the lung and the brain were not examined bacteriologically so that their relation to the occult focus in the sigmoid might have been made more explicit.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

THE PRIVATE CLINIC SYSTEM:

An Important Discussion.

At a general meeting of Fellows of the Royal Society of Medicine held on June 16th the President, Sir **John Bland-Sutton**, in the chair, an important discussion took place on private clinic systems in this country.

The Problem of the Private Clinic System.

Sir **Thomas Horder** opened the discussion. He said: If I interpret my function aright this evening, Mr. President, it is not to emphasise my own personal views upon the subject of our discussion, by particularising as to the actual form that I think the private clinic should take in order to meet what many believe to be a growing demand, so much as to refer briefly to various aspects of the whole question, and thus test the opinion and collect the views of colleagues working in different branches of medicine.

The actual wording of the subject of discussion has itself been difficult. I shall assume that one of the things we have in mind this evening is a consideration of what is conveniently termed "group diagnosis" and "group treatment," since this idea, as I understand the matter, is the debatable factor in the conception of the modern "private clinic."

Group Diagnosis and Group Therapy.

There is, of course, nothing new in the conception of group medicine.

1. The principle is in daily operation in most of our general hospitals, where each of us has the great advantage of the opinions and special technique of our colleagues in the investigation and treatment of our patients. In these institutions, again, patients are "transferred" frequently from one ward to another, and from one out-patient department to another, so as to secure for them the benefit of the service most nearly adapted to the nature of their diseases. That the principle can operate under the same roof, as it were, and that we can meet in consultation about cases of mutual interest without loss of time either to the patient or to ourselves, are two great assets in our hospital practice the value of which can be scarcely over-estimated.

2. In our private work the principle of group medicine is also being acted upon constantly. We all know where to get reliable expert help in regard to investigations which we judge to be likely to yield important facts supplementary to our own examination of the patient. If the nature of the case is, in the main, outside our province, we pass the patient over to the colleague most likely to help. As for diagnosis, so also for treatment.

But in private practice all this desirable collaboration does *not* go on under the same roof, nor are there means of securing the colleague one wants without much loss of time both to the patient and to his advisers; there are no days and hours which are fixed for attendance at a known place where the expert is available for consultation.

Now it will scarcely be denied that the facilities for group practice afforded by general hospital conditions lead to increased efficiency so far as the patient is concerned, and also contribute more to the advance of medical knowledge. This fact is recognised by the public as well as by the profession. It seems but a natural corollary that some adaptation of the same method to private practice is desirable, and should be seriously considered. It is a question whether such a development is not already overdue. It is also a question whether, if the profession does not itself arrange facilities for group medicine, and itself control the form in which the principle be exploited, the public may not force the doctors' hands by efforts of its own, probably destined to yield less efficient results, and almost certainly many more professional complications. That extraordinary venture in New York, calling itself "The Life Extension Institute," to which many of the best known and most reputable members of our profession in the States and even a few in our own country are acting as medical advisers, is really a reflection upon the persistence of the idea that one man can any longer be considered capable of coping with the whole gamut of medical knowledge as it exists to-day.

Bound up with the principle of group diagnosis and group therapy is the problem of the nursing home. The "patient of moderate means"—a type that has increased greatly since the war—wonders why little or nothing is still being done to improve in radical fashion the present unsatisfactory conditions in this connexion. If the development of group clinics hastens the arrival of large institutions properly equipped and administered, which shall replace the innumerable small converted private houses in which most of our nursing-home patients are at present being treated, it would probably be welcomed for this achievement alone.

Before any clinic system, whether it embody the notion of group medicine or not, can prove itself an advance upon our present methods, I suggest that it must be so planned as to ensure two advantages:—

(1) It must supplement the ordinary routine physical examination of the patient by providing facilities for expert investigations and thus rendering the diagnosis fuller and more accurate.

(2) It must offer facilities for more thorough and therefore more beneficial treatment than can be undertaken by the individual practitioner.

The Aims of a Group System.

Aside from these two advantages a successful group system should aim at two other benefits:—

(3) It should save time for both doctor and patient, but without sacrifice of efficiency.

(4) It should save money for the patient, again without sacrifice of efficiency.

If I may assume that the first two desiderata must be fulfilled, it is clear that certain private groups and clinics now existing, or under consideration, are out of court. I will mention two of these in order to define the subject more nearly:—

(1) A practitioner, working with a number of juniors, who are in effect his assistants, who are paid by him; and who have no special knowledge or training;

(2) A number of practitioners or consultants of equal status and experience, working together, but not chosen so as to be representative of various branches of medicine.

With the first of these we are, of course, familiar. Even supposing that the senior man sees all the patients, which he rarely does, such an arrangement does but multiply his own individual activities, it adds no extra value to them. I am not sure if the second of these groups exists in this country. In U.S.A. there are several such groups, sometimes miscalled "diagnostic clinics."

On the other hand, there are two forms of the private clinic which, on reflection, would appear to operate so as to fulfil the desiderata mentioned.

(1) A number of practitioners or consultants of equal professional status, working together, chosen carefully so as to be representative of various branches of medicine ("hand-picked," as our American cousins term it). This constitutes a true group.

(2) A practitioner or consultant of great experience and balanced judgment who, after taking a careful history and making a thorough routine examination, refers the patient to one or more specialists for expert investigation and report. This does not constitute a true group.

Considerable reflection and some experience lead me to believe that both of these systems are practicable and that both of them should be encouraged. I propose briefly to compare them, and to consider the difficulties that beset them, as well as the benefits to be expected from them. For convenience I shall term the first the "*group clinic*" and the second the "*personal clinic.*"

The Group Clinic.

The group clinic has certain advantages over the personal clinic. It caters for patients having a much greater variety of diseases because its staff represents several different branches, whereas the personal clinic is likely to attract mainly (or only) those patients whose ailments are known to be of special interest to the chief. Again, the group clinic will naturally have some arrangement by which the constituent members are readily available for the expert examination of any patient—their hours of attendance at the clinic would be known, and it would therefore not be difficult to have all the consultations going on under the same roof, though this is not, of course, essential. The chief of the personal clinic must make his special arrangements with his experts, entailing loss of time and much secretarial work. Meetings of all the members of the group clinic would take place at a settled time, and general discussions about difficult cases would be possible. The chief of a personal clinic would rarely, if ever, meet all his experts together. And again, the group clinic can undoubtedly add more valuable, and more authoritative, knowledge to medical progress than can the smaller institution; its records must necessarily deal with larger numbers and must reflect a wider range of opinion. This is an important consideration.

The Personal Clinic.

On the other hand, the personal clinic has certain advantages. The chief is brought into close touch with each patient, a very valuable factor in practice: in the group, although this is possible for each member and each patient originally sent to him, it would tend to lapse in respect of the patient whose main trouble is found to concern another man more than the man who first sees him. And the personal clinic scores heavily by possessing someone who can act as responsible agent at all of the three critical points in every group system; the point where sound judgment is needed to decide what expert examinations, if any, are desirable to supplement the general survey of the patient; the point where the various expert reports are coördinated or integrated so as to arrive at a full diagnosis; and the point where the programme of treatment is decided upon. It is true that the group clinic might choose one of its number to act as assessor in this manner, but this would almost certainly lead to serious difficulties, and would probably strain the friendly relations of the group not a little.

It seems certain that these three crucial points must be borne in mind and carefully provided for; *upon them depend the main success of any form of group medicine.* I think it is generally agreed that to send a patient the round of a number of experts quite indiscriminately, or to fail in the proper integration of the expert reports, or to be either scrappy on the one hand, or over-elaborate on the other, in formulating the therapeutics indicated by a study of the case, is to bring the whole position of group medicine into disrepute.

Finance.

Then in the very pertinent question of finance, there are obviously much greater difficulties facing the group clinic than the personal clinic. In the group clinic it is hard to see at present how a flat rate fee can be arranged for the patient without considering the members of the group to be, in the legal sense, partners. And if they be partners, is a Member or a Fellow of the College of Physicians eligible to work in such a group? In the case of the personal clinic a flat-rate fee may be charged by the chief to cover his own survey, certain clinico-pathological and other investigations, and his "integration" of expert reports, and the specialists may be paid their customary consultation fees as extras.

Certain Difficulties.

As already suggested, the formation and the operation of the personal clinic are fraught with fewer difficulties than is the case with the group clinic. And yet there are many who think that the group clinic, once the initial obstacles are overcome, and the idea has ceased to seem strange, is destined to do more for patient, doctor, and medical science than the one man clinic can possibly do. Let us look more closely at some of the difficulties facing the group clinic, and also at some of the reasons alleged against the system.

1. *The Preservation of Personal Contact.*—Can the personal contact between doctor and patient, which most of us consider to be so important, be preserved? The answer seems to be that it can, but that there is a definite tendency for it to lapse. This lapse can be prevented, either by the group being no larger than is absolutely necessary to cover the main branches of practice, and by each member of this compact group recognising the importance of himself guarding the personal relationship with all the patients who come originally to him, or by each group having a member detailed for this purpose; this member would rather naturally be the general physician of the group.

2. *The Difficulty of Finance.*—This has to be considered as it affects the patient and as it affects the group. It is perhaps a better scheme to charge a relatively small flat-rate to cover the general survey and preliminary clinico-pathological investigations, and to surcharge for whatever expert examinations are decided upon, than to fix a relatively higher flat-rate to cover examinations by all the experts if these are necessary. In this way the group system escapes the criticism of exploiting the patient by superfluous examinations which increase his expenses unnecessarily. Financial arrangements between the members of the group probably represent the most difficult question of all. Should the distribution be upon equal terms, or based upon the number of patients introduced to the group by each member respectively, or upon the number of hours spent at the work of the clinic? A group clinic doing successful work in the States adopted the somewhat bold and decidedly candid plan of sharing fees in proportion to their incomes on entering the clinic, with an agreement to take equal shares at the end of three years. I hope that some speakers following me may have other concrete suggestions to offer.

3. *Legal Relations between Members.*—The question of finance as it affects the group is bound up with the legal relations existing between its members. Here, again, are matters needing discussion. Is a deed of partnership the best form of relationship between the workers? Or would an incorporated body give them a better basis for good work and amity? Shall they be whole-time or part-time men? It is highly probable that quite successful groups may be established without uniformity in these matters.

4. *Possible Disturbance of Cordial Relations.*—Will the advent of the group clinic tend to disturb those cordial relations between members of the profession which we all strive to preserve? This is, of course, one of those fears which only care on the part of the men in the group can dissipate. There are certain privileges which it will be well to guard in order more surely to avoid the growth of undesirable cliques; the right of any patient to avail himself of the opinion of a specialist outside the group should be unalienable, and it will perhaps be equally important to permit overlapping of groups, assuming that the organisation of the group admits of this.

Conclusion.

There are other points which call for discussion; but I have already said enough by way of introduction. It would seem that the private clinic, supervised by one man, who is fitted by nature, by training, and by experience for such work, has up till now been more easy to set going in this country than the group clinic. And we must remember that Great Britain is not the United States, and British patients are not Americans. All the same, it seems highly probable that the group clinic will soon become a successful British institution, though its constitution and its mode of operation will remain British. Initial experiments will doubtless be looked at very critically, and early efforts will reflect the courage of the men who embark upon the scheme. Group medicine is obviously much better adapted to urban than to rural conditions. Not all men are qualified by temperament to act with others in a group; this fact will be patent to all of us. But given due recognition of this fact, a sense of loyalty within the group, and a desire to make the patients' welfare the paramount consideration in all aspects of the work—given these things, there is probably a much greater future for the group clinic than for the personal clinic. Our present forms of practice are satisfactory up to a point, and they are typical of British individualism. But they often lack cohesion, they are not infrequently extravagant both of time and of money, and it can scarcely be claimed that in the case of many complex, obscure, and chronic disease-processes the patient is getting all the help that present-day medical knowledge and technique can supply. The words of Dr. L. F. Barker, an ardent apostle of group medicine, are not exaggerated, when he says: "No single person can, any longer, hope to attain to equal skill in the use of the many instruments and procedures of diagnosis. And the same may be said of the complexity of modern therapeutic technique. No general practitioner, no surgeon, no physician can any longer, unaided, give to patients the benefits that they can, in the more obscure cases derive, and have a right to expect, from his efforts when combined with the properly coördinated (and subordinated) activities of a group of adequately trained medical and surgical specialists."

TEAM WORK ORGANISATION.

Sir HUMPHRY ROLLESTON said: The expression "Team Work" first became familiar in connexion with research into problems necessitating collaboration between experts in various branches of medicine —for example, the clinician, the physiological chemist, the bacteriologist, and the pathologist. On the advantages of such schemes of work there is no question, and to-night's discussion is directed to the consideration of team work in the diagnosis and treatment of individual patients rather than in the advance of clinical medicine as a whole. As this method constitutes that employed in ordinary well-equipped general hospitals, the issue before us is narrowed down to its adoption in private practice. In other words, to place within the reach of the rest of the population the same complete investigation and varied treatment that the necessitous poor have in the large general hospitals or, more briefly, to provide collective instead of individual medical attendance. This, again, is not a novel notion; firms of medical practitioners often constitute themselves with the view of covering more or less completely the large field of medicine and its special branches. Thus in choosing a junior partner preference is given to a young man with a special surgical bent and experience; and from time to time the various partners take special courses to qualify themselves as local authorities in eye, throat, X ray work, and so forth. But what is comparatively recent is the further development of this idea into the organisation of combined expert medical and surgical diagnosis and treatment such as has been carried to its logical conclusion by the phenomenal success of the brothers W. J. and C. H. Mayo at Rochester, Minnesota. This institution, which slowly grew up under the guidance of exceptional organising ability, has recently by its endowment as the Mayo Foundation become a permanent educational and research body, and so has undergone a further development. In its previous stages it showed the way for a complete surgical clinic on the team work lines, and the example thus set has aroused the sincerest form of flattery. Naturally, the rest of America has not been backward, and the practice of what is called "Group Medicine" has spread widely in the smaller towns. In large centres the paying wards attached to teaching hospitals have long supplied this need; and it is noteworthy that the attending physicians and surgeons in many hospitals in America have their consulting rooms in the hospital, much to the patients', their own, and the hospital's advantage. The method of thorough examination of a patient by experts of all the specialties and the final assembling of the accumulated data by the supervising medical man or general diagnostician, who is the head of the team, or what Sir Thomas Horder called "the personal clinic," has been described in detail by Prof. Lewellys Barker,[1] of the Johns Hopkins Hospital, who has elaborated the system from the physician's standpoint.

As to the personnel and arrangements of a team work organisation, there is room for much variation according to the aims of those concerned in directing it. It might consist in miniature of an up-to-date hospital with beds for observation, laboratories, rooms for X ray and other examinations, and an operating theatre; the staff would consist of a physician or physicians, a surgeon or surgeons with assistants or colleagues with special knowledge in particular departments, bacteriologist and pathologist, radiologist, and so forth, with a resident secretary who should combine these duties with those of resident medical officer. Or this team work might be confined to cases of a medical or surgical character —for example, those of obscure illness requiring metabolic and chemical examination, and patients with nervous or gastro-intestinal disorders.

As to the clientèle of such a unit, the patients might be merely those of members of the team who have united their forces and practices so as to economise time and obtain more satisfactory results; or such a team work organisation might receive patients from outside practitioners for purposes of diagnosis, and return the patients with a report much in the same way as the Clinical Research Association reports on blood and other examinations. In large cities there would be room for both these forms of institutions; the private arrangement would perhaps be better suited for large than for small towns; for in a small town a private team might act injuriously on practitioners not members of the team and tend to freeze them out, thereby damping down healthy competition and engendering cliqueism.

Team work in an organised form is certain to come, if indeed it has not already arrived, but in this discussion its uses and possible abuses should be considered, and these may be briefly referred to under the following heads:—

1. From the patient's point of view, there can be no doubt that a systematic examination by all available methods of the laboratory, X rays, and so forth, will be a great advantage and will economise time. Financially, although the initial outlay may appear considerable, the ultimate gain may compensate; it is perhaps reasonable to believe that with the arrangements concentrated in one establishment the inclusive charge would be less than the amount of the fees now necessitated by examinations made as occasions seems to demand. It might be suggested that, although more extensively analysed, the patient might suffer from a multitude of counsellors, inasmuch as he would be regarded more as a machine out of order than as a human being who is out of health.

---

[1] Barker, L.: New York Med. Jour., 1918, cviii., 489–493, 577–582.

2. From the point of view of the medical profession it is obvious that by having the facilities of an up-to-date hospital and of expert advice from his fellow team workers, the medical man would get through his work in a much more satisfactory fashion and with a minimum loss of time. Medical men who are not attached to a team, on the other hand, would be left out in the cold unless the team work was so far available to them that they could send their patients there for expert opinion and if necessary treatment; and even then they would to some extent suffer in prestige.

The financial aspects of team work will require careful consideration both as regards the relations of the individual members of the teams and as regards the reputation of the profession as a whole. The question whether an individual shall be, so to speak, a whole or part-time member of a team is a matter of private arrangement, but obviously of considerable importance from the point of view of a consultant in active practice who joins a firm. If he be a whole-time member all the fees that he earns—e.g., for long journeys—would go into the common fund, and this would be justified on the assumption that his reputation may be derived from the team of which he is known to be a member.

From a financial aspect a team of consultants and experts would be in the same position as a firm of general practitioners, and the members of the team might be regarded as shareholders in a company trading in medicine for profit.

POINT OF VIEW OF THE GENERAL PRACTITIONER.

DR. **DRURY PENNINGTON** said: I have spent nearly two years trying to discover why there should be any objection to any body of men grouping themselves together for their mutual benefit both financially and scientifically. Individually, men of all branches of medical work will agree readily enough that some scheme is needed whereby their work should be better coördinated with that of others. Collectively, the various medical bodies have seemed curiously shy, and the most concrete objection that I have thus far been able to extract is that "the time is not yet ripe."

In my view the late world-war has ripened a good many fruits, at least it has forced mere flowery speculation into fruitful action in many walks of life. Politicians at the end of 1918 were preaching a new heaven and a new earth! Look around for the fulfilment of this flippant prophecy and you find only one outstanding change from the days before the war. This change is summed up in the word "combination." Banks have grouped themselves into a few huge machines. Trade in all directions is seeking larger and larger combinations in order to exist at all, and by no means least, labour has so grouped itself that at present we are experiencing the worst economic crisis within living memory—an instance perhaps of faulty organisation due to false ideals.

Can we alone as a profession smugly continue to plough our lonely little furrows, and say, "Thank God we are not as these others." If such complacency ever really existed in fact, the last three months in Harley-street must have brought an unpleasant awakening.

Therefore I say with all the emphasis at my command: The time is over-ripe. We need a fresh adjustment to new conditions and for two main reasons:—

(1) The rapidly decreasing power of the public to pay the old dues, and

(2) The formidable increase in the cost of diagnosis during the last 15 years.

These two considerations alone would justify such a meeting as we are holding to-night, but there is yet another aspect, one of even greater importance, and that is the scientific rather than the merely commercial development of our craft.

Now thus far I have doubtless merely paraphrased the opinions of previous speakers this evening, but I am anxious to focus attention more especially on the position and needs of the general practitioner in relation to present-day difficulties.

Speaking as a general practitioner myself I have found the following main problems arising in the course of a fairly varied practice. Time and again I am confronted with the chronic case with a multiplicity of symptoms which in the nature of things probably arise from some fundamental cause or causes, and before I can assure either my patient or myself of the accuracy of my diagnosis, I find it necessary to apply to a bacteriologist or radiologist—often both—to give me some of the missing links in the chain of evidence. This course may be exhaustive and thus scientifically desirable, but what of the patient's pocket? Here we arrive at my second frequently encountered difficulty, often only surmounted by my either going round begging for gratuitous service or, as often, of converting my fee into a payment on account for the patient.

More strictly on the scientific side I am faced with a difficulty of a rather different order. When as a country practitioner I was in the habit of regularly reading medical journals in an endeavour to keep abreast of affairs, I often found a most plausible article dealing with a problem that concerned me at the time. The writer was an entire stranger to me, and despite the usual advertisement of degrees in the superscription, I was wholly unable to estimate the accuracy of a single statement made. The only practical solution lay in the empirical application of the advice to the next likely patient—a wholly unmoral proceeding unless the patient is told that he is being subjected to a clinical experiment, and that if no success attends the effort no charge will be made. I do not think my experience in this respect is in any way unique. I may say it is a common practice among others similarly situated.

Surely it would be of infinitely greater value to all concerned were it known that an article written by John Smith had been submitted to the scrutiny and criticism of several colleagues who had seen the same cases upon which the article had been based. And here let me add from a general practitioner's point of view it is not enough that a number of surgeons should pronounce favourably upon a suggested panacea; we are quite as concerned to know what the psychologists have to say in opposition or agreement on the same subject.

The Practitioner as Assessor.

No one could more appreciate the value of the advice and technique of the specialist than myself, but while I am a convinced advocate of all forms of specialism, it is my concern to get results in the individual rather than in the mass, so that I become very conscious that specialism tends sooner or later to mental myopia and that the whole is apt to be lost in the part. It is therefore not wholly surprising that I find myself more and more being forced out of the position of being the mere hack of consultant autocracy into the far more difficult rôle of arbiter between the oft-times conflicting opinions of rival specialists. I conceive it to be my duty to keep a watchful eye upon the whole individuality of the patient in regard to any advice that may be offered as to any one portion of his anatomy—in short, I find difficulty in adequately discharging the office of assessor to opinions of consultants as they are now given.

You may argue that my difficulty in this respect is of my own making, that it serves me right for arrogating to myself functions for which I was never intended, and that I should have been content with the subordinate rôle of a general practitioner. I submit in reply that the status of the general practitioner has changed very considerably during the last 20 years. He can now actually be trusted to make an accurate diagnosis of an acute appendix or pneumonia! And I venture to add with all deference that while there has been a perceptible rise in the general level of intelligence among the hack workers in medicine, there has been a corresponding falling off of the need for the general consultant physician for the purposes of diagnosis and therefore also of treatment.

And here I may perhaps indulge a human weakness and prophesy that before many years pass the general consultant physician will cease to exist but will find his regeneration in the rôle of an assessor to a team, to his very great content and profit.

What, then, of the general practitioner in this scheme of things? As I see it, the success of any group will largely depend upon the acumen and personality of the assessor. I use the word acumen designedly because it does not exclude the man with experience of men, the man of common-sense and therefore the type not always found among the ranks of academic successes. In less veiled language, a man's diplomas or degrees will cease to be the only criterion. For that matter the public is realising more and more that the man of many degrees is by no means deified by reason of such degrees, and until the time arises when someone invents a system whereby personality and common-sense may be estimated in terms of marks, degrees per se will be less and less the hall-marks of efficiency.

Thus team-work by no means excludes the employment of the general practitioner in the rôle of assessor, for it is certain that unless the general practitioner is up to his work his colleagues will find reason not to collaborate with him.

Conclusion.

To sum up my various points:—

1. The time is ripe for the adaptation of medical practice to the needs of modern science and modern economics.

2. The formation of teams all over the country—each adapted to meet local requirements—should supersede the present system of individualism.

3. Evils which exist here and there in private practice would tend to disappear when the individual has no longer only himself to consider.

4. Any evils which team-work might be thought to engender would be far more easily detected and corrected than is the case now.

Professional Feeling in the Matter of Private Clinics.

Mr. **Bishop Harman** said that as chairman of the Hospitals Committee of the B.M.A. he felt honoured in being asked to contribute to this discussion, but he wished to make it clear that he had no authoritative information to give. There were certain points, however, that might throw light on professional feeling in the matter of these private clinics. The idea of professional combinations was not new. During the war the Central Medical War Committee urged private practitioners to combine (*a*) to foster subdivision of their work, to promote economy, and to achieve higher attainment in special branches of the profession; (*b*) to facilitate continuity during periods of illness, holidays, and study. The recommendation was well received and had been acted upon with success. A similar combination for in-patient work in a private hospital in the provinces had also been under review and no exception had been taken to the idea. Mr. Harman thought that in general no objection could be made to the principle of combination, either for domiciliary treatment or clinic work. It was the necessary outcome of the growing complexity of medicine, and the logical corollary of the established principle of hospital practice. It was now desired to extend those benefits which patients at a charity obtained as a matter of course, to private patients who were able to pay their way.

In practice certain difficulties might arise. The cost of establishing an efficient private clinic might be so high as to prevent a combine of capable doctors from establishing a clinic on their own resources. They might be tempted to accept lay finance, which might mean lay control or direction; the lay element would desire financial success, and the temptation to some form of advertising would be difficult to combat. Some difficulties akin to this had arisen with regard to establishments, originally founded as quasi-medical institutions, which now combined medical work with facilities for legitimate entertainment. A risk such as this could be guarded against by a proper legal deed of constitution for each clinic before it was set up. Again, if powerful combinations became numerous they might exert an inhibitory influence on the careers of younger members of the profession, who could not or would not seek admission into existing combinations. Existing combinations might become powerful enough to prevent the establishment of new combinations and thereby act detrimentally on the development of professional knowledge and skill. Possibilities such as these foreshadowed a risk of professional competition far more serious than anything now existing between individual practitioners or partnerships, and it was difficult to see how these dangers could be guarded against. Lastly, there was a thought of risk in some minds that the commercial aspect which a costly clinic would introduce might lead to patients being exploited for profit to the combine and not treated primarily for the benefit of the patient. This was a risk present in any form of practice, individual or combined, and there was no safeguard against it other than that of the high standard of integrity of the several members of the profession. So long as that standard was as high as it is to-day the risk was minimal, and there was no reason why we should fail to maintain that standard. In conclusion, Mr. Harman cited some actual expressions of experience made to him by intelligent patients, which showed with what favour these patients viewed such arrangements as were suggested for their benefit.

The Surgeon's Point of View.

Mr. **W. H. Clayton-Greene** said that as the main subject had been exhaustively dealt with by previous speakers he proposed to touch only on that aspect which affected him as a surgeon. In a discussion on any proposals for change the adequacy or inadequacy of the present system must not escape consideration. To Mr. Clayton-Greene the existing system appeared most unsatisfactory. Before coming to the meeting he had looked up the distance between London and Banff and had ascertained that the distance between London and the only resident establishment where diseases of the alimentary tract could be thoroughly investigated was 587¼ miles! In trying to estimate the advantage of the private clinic system, the surgeon had to consider what help he would be likely to receive from close association with his colleagues (1) in diagnosis; (2) from an operative point of view. Mistakes in diagnosis were made by every surgeon, and radiologists, bacteriologists, and pathologists were at least as fallible when working without clinical evidence, but in Mr. Clayton-Greene's opinion mistakes would be less likely to occur if patients were consulted over by surgeons and physicians jointly with the additional help of the specialists. The system of *sending* the patient to the specialist was wrong, and the habit of sending a piece of the patient still more reprehensible. The dangers of this latter method were exemplified in a case in which Mr. Clayton-Greene had recently been associated. A digital tumour had been sent to a pathological laboratory as ? sarcoma, and since the tumour showed numerous round cells, the suggested diagnosis was confirmed. The true nature of the condition—a granuloma due to syphilis—was elicited in a consultation which, had it taken place earlier, might have saved the patient from the loss of a useful part of his arm. This was the diagnostic aspect of the question. As to the operative side, the work done in most nursing homes contrasted unfavourably with that done in hospitals, which was essentially team-work. Even in the best nursing homes the same standard of efficiency would hardly be reached. Operations in private houses were even more difficult to arrange. For all these reasons private clinics appeared desirable. It had been said that the clinic system was foreign to British ideas, but if this system did its job well the British public would march to the door of the clinic, even if to reach it they had to travel 587¼ miles.

The Business Side.

Mr. W. S. DICKIE said that the problem had to be considered from the point of view of the patient, of the medical practitioner—using the term in its widest sense—and of the credit and reputation of British medicine. With regard to the patient, his interest consisted in getting the best possible treatment, attention, and environment at the lowest reasonable cost. The general public was becoming much more critical than formerly with regard to the accommodation available, and comparisons between British and foreign provision for the treatment of private patients were much to our disadvantage. As to the medical practitioner, it was obviously to his interest to have at his command facilities for examination, diagnosis, and treatment of his private patients at least equal to those existing in well-equipped general hospitals.

If we assumed that existing conditions were unsatisfactory, how were they to be remedied? Provision might be made at existing voluntary institutions for receiving a certain proportion of paying patients, and this plan, on a limited scale, was already in operation in various places. The plan had certain obvious advantages. There was no need for any initial capital expenditure; existing buildings and administrative machinery were utilised, and already installed technical plant—probably not running at full capacity—was available. The disadvantages were that (1) in some, perhaps in many institutions, any such provision would be outside the scope of the original trust foundation and the present constitution; (2) without important structural alterations or extensions any provision made by existing institutions would be insufficient to meet the needs; (3) provision made by a voluntary hospital could hardly be made available for the use of medical men other than the members of the honorary staff of the institution; (4) a bureaucratic and institutional element between the practitioner and his private patient would almost inevitably be introduced; (5) evidence from America and the continent of Europe showed that the combination of paying and non-paying patients in the same institution worked badly.

Another suggestion was that the necessary provision might be made in or additional to existing rate-supported institutions, but in Mr. Dickie's opinion all the arguments against the provision of the desired accommodation in voluntary institutions applied here even more strongly. Again, special provision might be made by local authorities for building and equipping hospitals for private patients, these institutions being available to the general public at rates to be fixed on an economic basis, so that the hospital should not only pay its way but provide a fund for redemption. The professional service might be open to all registered practitioners, fees being a matter of private arrangement between doctor and patient. Mr. Dickie said that though this plan at first sight appeared to provide a reasonable solution of the problem, the ultimate development would be uncertain, and it might lead to rate control not only of the hospital, but also of the financial and other relations between doctor and patient. Mr. Dickie believed the best solution would be reached by private enterprise, working on business lines untrammelled by association with existing charitable or voluntary or other public bodies. The question arose whether the income could be expected to meet current working expenses, pay reasonable interest on invested capital, and provide adequate sums for upkeep and depreciation. As regards capital cost, no institution for the treatment of private patients could be considered satisfactory if it had not been specially designed, built, and equipped for the work in view. The converted building was difficult to work and costly in upkeep. Capital expenditure was commonly expressed in terms of cost per bed (though this was not in all respects a satisfactory basis), and Mr. Dickie had calculated that the cost of a complete private hospital need not exceed £500 per bed, and in some districts could be less. He uttered a strong protest against elaboration and luxury, which were no more necessary in the treatment of the wealthy than of the poor, and gave his grounds for believing that an adequate private clinic could be constructed at about 1s. 6d. per cubic foot. As to running expenses, Mr. Dickie claimed that the housekeeping costs need not be greater than those of general hospitals. The medical and surgical expenses were also comparable, since the private patient used no more drugs and dressings than the patient in a public institution; surgical instruments, catgut, and gloves, would be provided by the surgeon, and though wages and salaries might be a proportionately larger item in the private institution, Mr. Dickie expressed his confidence that the running costs of an efficient private hospital need not exceed, and ought not to exceed, the comparable expenses of the voluntary hospital, especially as the private hospital had no costly out-patient department. He therefore used the figures of voluntary hospitals as the basis of calculations. Running costs of voluntary hospitals were at the present time about £3 per patient per week, and he estimated that an income of £7 a week per bed would keep a hospital of, say, 50 beds on a sound financial basis. As to the source of the capital required, Mr. Dickie deprecated the old idea that it was improper and unprofessional for a medical man to have a financial interest in the institution to which he sent his patients. Conditions had changed, and nowadays it was the duty of the practitioner—medical, surgical, obstetrical or general—to be financially interested in the establishment to which he sent his patient if he wished to safeguard that patient's interests. The professional man's active interest would be the element which would lift an institution from the level of a dividend-producing factory to that of an actively beneficent social factor.

Mr. Dickie considered that the medical man should be financially interested in such an institution openly and in association with non-medical shareholders. If a score of medical men combined, put down £500 to £1000 each, and then went to their business friends with a scheme there would be no difficulty in raising an equivalent sum from these friends, who would recognise the need for an institution and its prospects of success. Mr. Dickie warned his colleagues that if they did not themselves proceed to the organisation of a private clinic system it would be done for them by cosmopolitan financiers, who would do it well but would be concerned only with the fees they could obtain and the dividends they could draw.

Some Practical Suggestions.

Dr. G. C. ANDERSON said that he was sure that any move on the lines of the private clinic system would be welcomed by the general practitioner. A general practitioner, anxious to have a second opinion upon a particular case, might be doubtful whether the opinion ought to be that of a physician, a surgeon, or a specialist in some other branch. If the case belonged to the poorer class and could be sent to a hospital it would not matter to whom the patient were directed in the first instance. If, however, the patient could afford to pay, the general practitioner might direct the patient to a surgeon, only to be told that the case was purely a medical one or that an X ray was required before a surgical opinion could be expressed. From a private clinic he could obtain a comprehensive report, most probably accompanied by a clinical diagnosis confirmed by X rays and bacteriological examinations. From the point of view of the public, also, the advantages were apparent. Modern diagnosis was now growing so formidable that very often patients had not sufficient means left for treatment after an accurate diagnosis had been established. The fees charged at a private clinic could be made more moderate than the present fees charged by individual consultants, because by combination the expenses would be materially decreased, and in this way also the receipts of the medical men associated with the clinic would tend to be increased. The general practitioner would be able to attend with his patient, and in this way he would tend to become more proficient in his own work.

There were several ways in which a private clinic might be worked. The team should consist of a number of practitioners or consultants of equal status, chosen in such a way as to represent all the different branches of medicine, with the possible addition of a medical assessor. A possible scheme of work might be that each member of the team would carry on all his own private work at the clinic. The second opinion available in an adjacent room would be an obvious advantage, both to the practitioner and to the patient. Entire freedom of choice could be left to the patient, by providing that if desired he might equally well consult for a second opinion a doctor who did not form part of the team. Each member of the team would draw his own fees from private patients seen at the clinic, but fees from patients sent by outside practitioners to the clinic for general diagnosis only would go into a central pool, upon which would fall the burden of the upkeep of the establishment. The expenses necessary for the conduct of the clinic would be met out of the central fund, the practitioners being thereby enabled to carry on their private practice without any expense at all, and any surplus from the pool could be divided annually. The team of practitioners would not get individual payment for general diagnostic work, but would gain indirectly owing to the diminution of their private expenses. The general practitioner who sent up the case for diagnosis would receive a comprehensive report, and would be free to adopt any line of treatment within his own competence that seemed best.

Arrangements for treatment at such a clinic might be provided, but the privilege of a patient to choose his own specialist should be preserved. The charges of a nursing home attached to the clinic would go towards the upkeep of the home, whilst professional fees would be paid direct to the surgeon or physician who had undertaken the treatment. All patients, other than those who wished to see a particular member of the team, would in the first instance be directed to a medical assessor, who should be a practitioner or consultant of great experience, who would make a thorough routine examination before referring the patient to any specialist. A pooling system for fees could only be made applicable to diagnostic work, fees for treatment being arranged privately between the practitioner concerned and the patient. Dr. Anderson did not think it would be in the interests of either the patients or of those practitioners if diagnostic work alone were done at the clinic. Observation wards would anyhow be necessary, and additional beds for treatment would probably follow as a matter of course. However, arrangements for treatment would lead to greater difficulties in connexion with finance. The expenses of establishing a diagnostic clinic could be provided by the team of medical men, but it was doubtful whether sufficient money would be forthcoming from this source for a nursing home as well. Once outside financial help was contemplated difficulties arise. From his experience as an official of the British Medical Association, Dr. Anderson realised that once the public was asked to aid in any way the financing of a nursing home the question of advertising would sooner or later be raised, and it was for this reason that he felt strongly that the control of private clinics, whether for diagnostic or treatment purposes, should be entirely in the hands of the medical profession.

Financial Benefit to the Patient.

Dr. A. F. HURST said that he had long felt that his work at Guy's Hospital was more thorough than his private work, and so, within the last few months, he had started a private clinic about 20 miles from London. Already he had found it infinitely more pleasant and satisfactory to work in private with a team. In his opinion the financial aspect of such a clinic ought to be entirely independent of the medical officers, who should, however, have control, and should not allow advertising. His own clinic was entirely removed from the idea of financial gain. It was financed by two members of the lay public. The services of an old regular R.A.M.C. quartermaster had been secured to do the administrative side of the work. From the patient's point of view there was a distinct gain, since the total fees he often had to pay to one specialist after another would be much bigger than the fee payable to the clinic. This fee was the same, however many investigations were done, save where the patient's means suggested some reduction. In private practice it was often doubtful whether an additional test would throw light on the condition, and the patient's means had to be considered; at a clinic this question did not arise, an exhaustive investigation was made as a matter of routine, and unexpected diagnoses not infrequently ensued. As to patients of moderate means, in Dr. Hurst's opinion these should benefit at the expense of those better off, and therefore some cases were admitted to his clinic at greatly reduced fees. The clinic should be regarded as a place where a prolonged consultation takes place. The saving of time to the medical officers was enormous, and, from the patient's point of view, though diagnosis might take a week, it was then probably as definite as it ever could be. A resident medical officer was an enormous help in relieving the senior men of routine work, and also in getting the initial history typed ready for his visit. Dr. Hurst gave a few examples of difficult cases which had recently been diagnosed at his clinic. The resident medical officer was in a position to examine a patient at any time of day or night when an attack of pain or other symptom manifested itself, and this fact alone was of incalculable diagnostic advantage. As to treatment, Dr. Hurst mentioned gastric cases as exemplifying the advantages of a consultation between surgeon and physician. In his experience twice as many patients presented themselves suffering from after-effects of gastro-enterostomy as from primary gastric symptoms. He did not suggest that this was not a good operation, but most people would agree that it is done too often, and with adequate medical treatment the patients would often recover without such drastic measures being resorted to.

On the motion of Dr. A. LAPTHORN SMITH, seconded by Sir THOMAS HORDER, the discussion was adjourned to a day which will be announced later.

New Inventions.

ALL-GLASS INHALER.

THE inhaler shown in the illustration is so constructed that on nasal or oral inspiration air is drawn into the main body of the bottle-like apparatus through a small opening in the "neck," passes down the central tube, bubbles through the inhalant, and becomes saturated. The medicated air then, through a by-pass, enters into the upper chamber or nozzle, and thence through the nose or mouth. The apparatus gives a highly saturated vapour with volatile drugs. It has been found beneficial in phthisis, laryngeal tuberculosis, nasal catarrh, and as a preventive of influenza; in rhinitis and suppuration of accessory sinuses—antrum or frontal—various forms of naso-pharyngeal catarrh, asthma, and bronchial trouble. The inhaler can be sterilised by boiling, and by a quarter turn of the stopper it can be safely sealed and packed for travelling with inhalant in it, ready for instant use. It can be obtained for nasal or oral inhalation or the nasal appliance can be used for either. Messrs. Allen and Hanburys, Ltd., 48, Wigmore-street, London, W., are the makers.

Reviews and Notices of Books.

ANNALS OF THE MIDDLESEX HOSPITAL AT CLACTON-ON-SEA DURING THE GREAT WAR, 1914-1919.

By COMYNS BERKELEY and VICTOR BONNEY. London: W. J. Clark and Co. 1921. Pp. 128. 10*s.* 6*d.*

THE branch of the Middlesex Hospital at Clacton-on-Sea was offered to the War Office on the outbreak of war as a complete surgical unit for 115 men and 15 officers. The offer was accepted and the hospital was employed as a First Clearing Hospital throughout the war. Owing to the fact that all the other members of the surgical staff were already employed on war work, the two gynæcological surgeons, Mr. Comyns Berkeley and Mr. Victor Bonney, volunteered to do the work at Clacton as resident surgeons, each living there and carrying out the whole work of the hospital for part of the week. The book before us gives a readable and interesting account of the work at Clacton. During the 4½ years, 9242 patients passed through the wards and were thus under the care of the two surgeons, who were personally responsible for all the medical and surgical work of the hospital except that some assistance was given in the matter of anæsthetics. The analysis of the cases given in Chapter IV. shows how varied they were and gives some idea of the labour involved. No less than 874 operations were performed, and all the X ray examinations were carried out by the two surgeons themselves, after a little coaching from the late Mr. Cecil Lyster. It is impossible to withhold a tribute of admiration for the patience, resource, and versatility shown by Mr. Berkeley and Mr. Bonney in the work here recorded. Many hospitals with an equal or smaller number of beds had a large staff to carry out the work, which was here done with high efficiency by two men. They have the satisfaction of knowing that the personal sacrifices they made in a time of national need set free other men for work abroad. The proceeds of the sale of the book are to be devoted to the funds of the hospital. The book is well written and contains humorous details of life in a war hospital. It is illustrated by photographs and a few sketches and caricatures, and we feel sure that it will appeal to a wide circle of readers.

DICTIONARY OF APPLIED CHEMISTRY.

Vol. I. By Sir EDWARD THORPE, C.B., LL.D., F.R.S. London: Longmans, Green and Co. 1921. Pp. 752. 60*s.*

IT is rightly pointed out in the preface to this volume that the war has exercised a great influence on applied chemistry, for it has led to an enormous expansion, more or less permanent, of certain branches both in this country and abroad. As there now appears to be some likelihood of a really stable chemical industry being established in Great Britain, the appearance of a revised and enlarged edition of this well-known work is opportune. The chemical manufacturer who proposes to make high-grade products, involving large capital outlay and technical skill, naturally hopes to sell his goods at a reasonable profit. In many, if not in most cases he cannot do so at the present time and, if the industry is to be kept going, some assistance, such as has been outlined by the Government, is an absolute necessity. The interdependence of chemical warfare and chemical industry is so well known that it would appear that Government aid to the industry is at least prudent from a national insurance standpoint.

The arrangement of the work is alphabetical. Vol. I. starts at A and ends with Calcium. Special articles are contributed by experts whose professional standing shows that Sir Edward Thorpe has done his best to make the Dictionary a true record of the present relations of chemistry to the arts and sciences

The medical man will find much which is interesting in this volume. Professor Barger writes on alkaloids, aconitine, adrenaline, and aloes, Professor Halliburton on bile, blood, and bone, and Dr. H. Robinson on anæsthetics. There appears to be little room for constructive criticism in the compilation and mistakes and misprints are rare. References to the literature are numerous, but some contributors adopt the rather irritating fashion of quoting the number of the volume and page but not the year: in the forthcoming volumes the year of the references should be added.

ANATOMY.

Anatomy of the Nervous System. By STEPHEN W. RANSON. London and Philadelphia: W. B. Saunders Company. 1921. Pp. 395. 32*s.* 6*d.*

Professor Ranson has produced a work intended for the use of the student of medicine, and has written with this object ever in mind. He begins with a short but clear exposition of the nervous system in invertebrates and lower vertebrates, and thus leads on to the study of the mammalian and human system. The descriptions of the various parts which make up the whole complicated system are good and excellently clear, but we confess to being left with an indefinite feeling of confusion, which is probably connected with the arrangement of the descriptions. The illustrations are instructive, but we would recommend more careful editing of the figures in future editions: for example, the trochlear nerve is wrongly labelled in Fig. 8, and a similar fault appears to affect the mesencephalon in Fig. 11. Such inaccuracies are the more regrettable as the author makes such good use of his figures in his text. The book contains also a short outline of a laboratory course for students of neurology, and ends with a full and excellent bibliography.

Manual of Surgical Anatomy. Third edition. By C. R. WHITTAKER. Edinburgh: E. and S. Livingstone. 1921. Pp. 429. 15*s.*

THIS third edition of a book which has a considerable vogue among students shows some enlargement and several new figures. Mr. Whittaker purports only to give outlines of the subject, and his book is a good example of a student's handbook of its kind. The diagrams serve their purpose, and we especially note one or two of the skiagrams as unusually good. Fig. 46, however, would perhaps give a more natural colour to the retina with better registering, and there is an evident gap in Fig. 2, which ought to contain lines indicating the contributory fibres to the outer cord. The text is readable and clear, but we think it would be as well to omit developmental descriptions where no direct reference is made to their bearing on pathological or clinical problems. We are glad to see that this is one of the few English books wherein Professor Marie's objections to the conventional teaching of the schools regarding aphasia receives mention, although no further details are given. A short appendix, giving Macewen's results in study of bone formation, epiphyseal junctions, and pelvic measurements, closes a good little manual.

ELECTRICAL METHODS IN UROLOGY.

Notions Pratiques d'Electrothérapie Appliquée à l'Urologie. Second edition. By Dr. DENIS COURTADE. With a Preface by *Prof.* LEGUEU. Paris: E. Le Francois. 1921. Pp. 241. Fr. 18.

As it title implies, this book deals with the uses of electrical methods for the treatment of diseases of the urinary tract. In addition, the physiology and pathology of the tract are described in so far as they are relevant, and also the properties and means of production of the various currents used for treatment. The subject is presented in the form of a series of lessons. The first four of these are devoted to physics and electro-technics and the remaining six to those diseases of the urinary tract which can be successfully treated by electrical methods These diseases are divided into two classes, of which one includes disorders of function, unattended by organic change, and the other those in which organic changes are present. In the fifth lesson the connexions of the urinary tract with the nervous system are described, and then the various neuralgias—renal, vesical, urethral, prostatic, and testicular—with their symptoms, diagnosis, and appropriate electrical treatment. In the sixth and seventh lessons functional disorders of the urethral and vesical muscle, such as paralysis and spasm, are considered, also nocturnal incontinence, spermatorrhœa, and a condition termed "pollakiurie" (frequency of micturition without increase of the total daily quantity). The remaining three lessons deal with diseases of the urinary tract accompanied by organic changes. These include inflammation and new growths of the bladder and prostate, urethritis, stricture, and polypi of the urethra. The author speaks of the value of ionisation, and 13 pages are occupied by a description of this method and its advantages. By means of ionisation drugs can be made to penetrate the mucosa of the bladder and urethra, while the epithelium of these passages is impenetrable by the process of simple diffusion. The treatment of strictures by electrolysis is described, and the method termed "electrolytic dilatation" (a combination of simple dilatation and electrolysis) is recommended by Dr. Courtade, who claims that it acts more quickly than simple dilatation, and that the benefits are permanent. If the stricture is composed of very dense scar-tissue, the method is slow, but good results are finally obtained.

The book is a clear exposition of the powers of electricity for the treatment of diseases of the urinary tract, and is based on the experience gained by Dr. Courtade at the Hôpital Necker during the past 30 years. He insists on the importance of knowledge of physiology and pathology for successful treatment, as well as familiarity with physics and electrotechnics. The first 99 pages contain an account of these subjects that can be clearly understood by anyone who is acquainted with the commonest electrical terms.

The English reader is left in some doubt regarding the method of action of high-frequency currents—other than by the production of heat, and elsewhere when more than one method of treatment is described, the reader is not always given sufficient indication of their relative values. The book is attractively written and is a valuable addition to the literature of medical electrology.

SIDELIGHTS ON THE EVOLUTION OF MAN.

By KARL PEARSON, F.R.S. University of London Eugenics Lecture Series. XIII. Cambridge University Press. 1921. Pp. 27 + 7 plates. 3*s.*

THE intention of this lecture is to set forth what evidence can be adduced from the study of a single bone—the femur—to support the contention that the line of man's evolution followed that of the fiercer of the Primate series, rather than that of the arboreal or more timorous group; that he is more nearly related to ancestors which produced the modern anthropoid apes than to those from which the gibbons have arisen. The point on the evolutionary tree from which the gibbons started, and certain alleged resemblances between Trinil femur and those of Dryopithecus, a fossil gibbon of great size, have for years been in dispute. Professor Karl Pearson is in agreement with Sir Arthur Keith in believing that the modern anthropoids—the chimpanzee, orang, and gorilla—left the direct simio-human stem at a more recent date than the gibbons. He regards the features of the Trinil femur as substantially those of modern man, and dismisses Dubois's view that the convexity of the popliteal space is evidence of near relationship to the gibbons, by showing that the same condition is not uncommon in modern human femora.

The author discusses in particular certain anomalies or deviations from the accepted anatomical description of this bone, the lateral protrusion, the degree of bowing, the hypotrochanteric fossa, "pilasters," and the third trochanter. He gives statistics and measurements of these features which strongly support his contention, although those relating to the third trochanter are not convincing. The significance of pilasters—occurring chiefly in bones showing excessive bowing—seems to be questionable. Professor Pearson says, "I doubt very much whether man ever stood upright until he had developed a pilaster," and the same might be said of the possessors of the rickety bones with which all are familiar. The causation of the pilaster in both cases must lie in the nature of the muscular pull in a curved bone.

So far as the femur alone is concerned the case is a strong one, and the use made of the numerous indices deserves further study. When applied to a single bone in this manner physical anthropology recalls the methods employed by Mr. Sherlock Holmes, in a case in which his client had left his hat behind him, to deduce the type of man he was.

PERSPECTIVE: THE OLD AND THE NEW METHOD.

By A. S. PERCIVAL. London: Longmans, Green and Co. 1921. Pp. 42. 4*s.* 6*d.*

MR. PERCIVAL, well known for his work as ophthalmologist and mathematician, has essayed the difficult task of writing a book on perspective that shall be both brief and lucid. The medical interest of the book is slight, and Mr. Percival has not thought it necessary to include the preliminary remarks on optics which, in other treatises, have mystified many art students. He comes straight to his subject and he sets out the rules of perspective dogmatically and comprehensively. What teachers at drawing classes, as well as their pupils, may thank the author in particular for is the opening section in which the field of view is explained. It is quite usual in books on perspective of far greater ambition than this treatise for the authors to make such muddling remarks on "distance," "station," "point of view," and "vanishing points," that the whole subject of artistic perspective, which requires a clear mind for its understanding, becomes involved in mystery from the start. So much information has never before been given in so small a compass, but knowledge packed closely by an author has always to be unpacked slowly by a reader. An art student to benefit by this small book must read slowly, pencil in hand, and be resolved not to read one line ahead of perfect understanding.

There are several misprints, which should be corrected in any future issues.

JOURNALS.

IN the *Military Surgeon* for May, Colonel A. N. Stark, who was medical officer at headquarters of the American Army in the St. Mihiel and Argonne operations ("Army Surgeon"), discusses the preparation by the surgeon of an army for the medical service of a battle. He stresses the need for full information of what is intended, observing that it is only relatively inexpert staffs which fail to give the senior medical officer information as soon as a movement is decided upon. The same thought is, by apt coincidence, expressed in the May *R.A.M.C. Journal*, where Major A. C. Osburn mentions it was only "after 1916, when brigade staffs became more inexperienced," that he had to find out for himself what his field ambulance was wanted to do. Colonel Stark goes on to say that after the chief surgeon has prepared the perfect battle scheme and has arranged therein for everything that can be foreseen, emergencies will still arise that can only be met by what he terms "esprit," developed in a spirit of mutual confidence and in friendly rivalry.—Major A. Parker Hichens, of the U.S. Army Medical School at Washington, speaking of anaphylactic collapse, recommends small doses of epinephrin and of atropin, though his 1100 gr. of atropin sulphate seems rather a large dose, 0·5 mgm. being the suggested metric alternative. He also recommends epinephrin for the urticaria which may arise after serum injections.

THE LANCET.

LONDON: SATURDAY, JUNE 25, 1921.

Notification of Measles.

MEASLES is a potent cause of preventable infant mortality. Usually the annual deaths from this disease are, roughly, equal to the total deaths from all other notifiable infectious diseases. Two articles in the present issue of THE LANCET, by responsible public health officers, discuss some aspects of the compulsory notification of measles, Dr. R. DUDFIELD, representing an essentially urban community and Dr. R. M. F. PICKEN, a suburban and rural area. In the light of these articles it may be well in the first instance to review the history of notification. Up to Jan. 1st, 1916, measles was compulsorily notifiable in the areas of a few sanitary authorities only who had obtained the permission of the Local Government Board to add it to the list of diseases notifiable under the Act of 1889. During the war serious outbreaks of the disease occurred among troops, which, as noted by Dr. PICKEN in the case of the Highland Regiment at Bedford, were sometimes accompanied by a very heavy mortality. It was therefore important that troops should not be billeted upon or located near, a population among which measles existed. An Order was therefore made by the Local Government Board requiring compulsory notification of the disease all over England and Wales from Jan. 1st, 1916. At the same time an attempt was made to induce sanitary authorities to take steps to reduce mortality from this disease among the civilian population by the provision of home visiting and nursing, and by medical assistance for cases of measles. Grants were promised to assist expenditure for this purpose. In 1918 an account of the administrative measures taken against measles by Dr. S. W. WHEATON, and a report on the prevention of mortality and disablement due to measles and pneumonia by Dr. A. S. MACNALTY, were published by the Local Government Board.[1] In the four years 1916 to 1919, 1,565,380 cases of measles had been notified, and 29,567 deaths had occurred from measles. On the termination of the war the position had to be reviewed. It was found that the country as a whole was not ready for action for the prevention of mortality from measles; and the Ministry of Health, which had succeeded the Local Government Board, decided that the continuance of the Order was not the best method of dealing with the problem. Accordingly the Order was rescinded, and from Dec. 31st, 1919, measles was no longer compulsorily notifiable throughout England and Wales.

The reasons that influenced the Ministry in taking this course are set out in the report of the Chief Medical Officer for the year 1919-20, p. 50. It is there stated that (1) notification of the first case in a house attended by a medical practitioner, and of each case in a household by the parents of the patient, is not an essential factor in a practical scheme for reducing mortality from measles; (2) that the sanitary authorities most active in this work have still to rely in large measure on other means than notification for finding out cases of the disease—e.g., through reports of health visitors and from schools, with the result that notification was redundant; (3) that on the other hand, in certain districts nothing followed notification, and it was difficult to justify the expenditure on notification fees. Grants in aid of measles prevention work were continued. The Ministry were willing, in any case where the sanitary authority had made suitable arrangements for reducing the mortality from measles, to make an Order on the lines of the rescinded Order of 1915 to apply to their district. This course was followed at Paddington, as related by Dr. DUDFIELD, where compulsory notification has been continued up to the present time without a break. The absence of compulsory notification need not prevent any sanitary authority from taking action for reducing the mortality from measles. All other available machinery must be called upon for reporting cases of the disease in children, such as inquiries by health visitors and school nurses in the course of their ordinary duties, the reporting of cases by school teachers, school attendance officers, and by parents. Measures should be devised for speeding up this information, so that it may reach the medical officer of health promptly, and the delay in receipt of the information, referred to by Dr. DUDFIELD, must be removed, that nursing assistance can come into operation sufficiently early in the course of the disease. It is noteworthy that the Registrar-General states the mortality from measles for the year 1919, the fourth year of general compulsory notification, to be 326 per million, which is by far the lowest ever recorded. It is to be hoped that all medical officers of health will give details of measures taken for preventing mortality from measles in their annual reports, and for securing notification without compulsion.

◆

Antimalarial Measures in India.

ALL who read on page 1393 of this issue of THE LANCET our review of the Report of the Sanitary Commissioner with the Government of India for 1918, the most recent Report yet issued, will feel that the well worn tag—"If preventable, why not prevented," has a special application to the incidence of many diseases, and in particular of malaria, in the Empire. In 1918 the death-rate from all causes in the general population of India was no less than 62·42 per mille. Much of the excess over the average rates in previous years was due to a huge influenza epidemic, and it must be admitted that preventive medicine was as powerless elsewhere as in India to deal with the scourge. No less than 11,134,441 deaths were registered as due to "fevers," against a decennial mean of 4,308,356. But in each 4½ million deaths registered under this term in India, it has long been officially conceded that not less than one million are due to malaria, and that the cases of sickness from this cause which do not end fatally amount to one hundred millions per annum. Were malaria contracted solely by the families of the labouring classes, and without taking into account capital vested in the producer, such figures would imply annually an unproductive expenditure of from £17,000,000 to £20,000,000, by reason of loss of wages, expenditure during sickness, and concomitant circumstances. The calculation, though a rough one, enables us to see how much money and how many lives are wasted and to what an extent industrial production is handicapped, because the preventable disease of malaria is not prevented. The carrying out of measures must fall to local governments, but the responsibility for legislation rests with the Government of India, whose rarely-exercised right of suggesting sanitary measures has been abrogated; and it is to the Government of India that the medical profession looks for active remedy. The principles which have guided the Government hitherto, in respect of the incidence of malaria, account for the lack of success in making a reduction of the disease in any area sufficiently large to appreciably diminish the loss of lives. As man after man has succeeded to office in the Government, he has inherited files from his predecessor which have taught that, in dealing with a tropical people, possessed of, or obsessed by, caste and religious prejudices, to go slowly is the only sound procedure. It would be well that some more active policy were adopted, although, broadly speaking, when dealing with 450 millions of people we cannot go faster than they want. It is first needful to create the demand for better things.

---

[1] Reports by the Local Government Board on Public Health and Medical Subjects. (New Series, No. 115.)

At the instance of the Royal Commission on the Sanitary State of the Army in India, which issued its Report nearly 60 years ago, namely, in 1863, there was established in each Presidency a Sanitary Commission in direct communication with the local government concerned—that of Bengal being also the advising body of the Government of India. During the short period these Commissions were allowed to exist, they gave an earnest of excellent work. But they were too far in advance of medical knowledge, and slowly but surely their functions were whittled away; first the members, then the president, and lastly the secretary, were got rid of. A single Sanitary Commissioner with the rank and pay of a Deputy Surgeon-General, corresponding to the rank of Colonel at the present day, then represented what had been a powerful body, supported by the Secretary of State, with which the Government of India had to reckon. But even this solitary officer was found to be an awkward factor if he ignored the time-honoured habits of procrastination or inertia in sanitary affairs, so reduction in pay and rank followed. In 1864–65 the Sanitary Commission of Bengal urged the appointment of municipal and sanitary services in all districts. Later the Secretary of State required the attention of the Government of India to the same subject for India generally. Successive Sanitary Commissioners of the other Provinces have urged similar reforms. But 1921 finds necessary action far from complete. Nor has the Government of India exhibited any more virile attitude in respect to measures more directly connected with malaria. Ross commenced his efforts to solve the malaria carrier problem in May, 1895. In December, 1896, the Government of Madras, recognising the importance of this research, urged the Government of India to place him on "special duty," so that full time might be at his disposal. This meant the grant of an acting allowance for the medical officer of a regiment to supply the vacancy, and a small percentage on the normal pay of the incumbent of the appointment. The Government of India, however, pleaded financial inability to meet the expenditure till February, 1898, and we seem to have heard that Ross personally received no thanks or recognition of any description for the work he had done in this connexion. The heritage of files in the offices of the Government of India still dictates that it is cheaper to place quinine on sale than to inaugurate with a whole heart large antimalarial measures in fever-stricken areas. The Government of India would seem still to regard drainage as of dubious utility, yet, and without the knowledge that we now possess of the causation of malaria, the members of the Royal Commission were able in 1863 to give the following definite opinion:—"One of the earliest discoveries of these facts was that intermittent fevers disappeared from places which were formerly ravaged after drainage of the soil and improved cultivation." In 1921 the effect of drainage is a matter of experiment in India with the aid of the Research Fund. Are conditions as to soil and water so very different to those found in other countries as to demand a waiting policy? It may be admitted that agricultural drainage may often be a better antimalarial measure than a mere ad hoc scheme. The prosperous and well-fed native becomes remarkably tolerant of the malarial virus. The problem, too, is different in every Presidency and often in every district. In Lower Bengal, where certain land is slowly rising above flood level, it is a geological-agricultural problem; in the cities the wells and water cisterns are to blame; in the Terai it is usually clear streams that drain the country perfectly; in some places it is railway borrowpits; in others dense jungle; in others again salt pools along the edge of the sea.

In view of all this it is satisfactory to find from the Sanitary Commissioner's last Report that at Secunderabad, as a result of abolition of wet cultivation and drainage of a tank, *commenced in 1917*, a decrease in malaria prevalence has occurred. This is the result of advice which has been offered by successive medical officers concerned since and probably before 1882, but with no result. And retrospect takes us back much further than 1882. Advice was tendered by a Special Committee on which DEMPSTER, of spleen fame, sat in 1845 in respect to Peshawar which was, and is, exactly to the point, but it remains, if not lost sight of, still "under consideration." This advice was as follows: "According to almost universal experience, there is no more ready way of generating malaria in such a climate as this than by profusely irrigating a stiff retentive soil, and therefore we believe it imperative not only to prohibit all canal irrigation within one mile of the Cantonment Pillars, but to take steps for securing the perfect drainage of the space included within this line." That important sanitary works have been completed in India none would wish to deny, but the fact remains that, notably in sanitary organisation and in major antimalaria efforts, the Government of India has failed to adapt its policy with changing times. Of this fact the annual recurrence of one million deaths from the preventable disease of malaria is evidence in the light of recent knowledge.

Hæmoglobin.

INTERESTING letters in *Nature* from Sir RAY LANKESTER have raised again some curious questions with regard to the occurrence of hæmoglobin in the animal series. For the original statements he was himself mostly responsible, nearly 50 years ago, and not much has been added since to the facts which he gave in the Proceedings of the Royal Society in 1872. All vertebrates have acquired the trick of having a rapidly moving circulating fluid carrying large quantities of hæmoglobin which is packed inside special corpuscles. It may be presumed that this method of arranging the supply of oxygen has been developed in adaptation to the increasing complexities of a delicate nervous system, and, in warm-blooded animals, to the immense rise in the activities of the tissues generally. The plan used by insects, which alone among invertebrates show a rate of metabolism comparable to that of mammals, of a system of air-tubes conveying air, as such, directly to the tissues, has not been pursued further in evolution.

Scattered about among invertebrates there are a number of instances of the occurrence of hæmoglobin, either inside cells or free in the body fluids. There are considerable quantities of it in such familiar objects as the blood of the larva of the fly *Chironomus* and the flat pond snail *Planorbis*, in the muscles about the tongue in the pointed pond snail *Limnæa*, in the nervous system of the sea-mouse *Aphrodite*, in the blood of earth-worms, and so forth. It seems to have developed in a haphazard way in species or genera in a variety of groups, and it is difficult to indicate precisely its utility. It is certainly not necessary for life, since the whole of it may be put out of action by carbon monoxide without any immediate ill-effects. The various species of *Planorbis* and *Limnæa* live together in the same ponds and rivers; both normally obtain their oxygen by coming to the surface and gulping in air; yet in the former hæmoglobin occurs in large quantities in the blood, while in the latter there is merely a trace in its masticatory muscles. It has been shown that the hæmoglobin of *Planorbis* is of advantage when the oxygen supply is very deficient, but the animal must seldom find itself in such situations, and its near relations and neighbours get on quite well without. Such advantage as hæmoglobin must carry with it would seem to be a very small one. Of the remote origin of hæmoglobin we have no information beyond a chemical relationship to chlorophyll and the pigments of red and blue-green algæ. The blue copper-containing proteid found in the blood of the larger mollusca and crustacea indicates another line of development but not a promising one, for the oxygen-carrying powers of this hæmocyanin are small compared to those of hæmoglobin. The odd cases where invertebrates are known to accumulate lead, zinc, and manganese are also perhaps worth consideration. The chemical intermediates which evolution theory postulates are as unknown as their morphological analogues: perhaps because they are colourless and have not been looked for very thoroughly.

For there is no doubt that "hæmoglobin" connotes to everyone its gorgeous colour: whole arterial blood is decorative enough, and when it is laked it is magnificent. As RICHARD OWEN remarks in one of his profounder moments, "Man is naked, and is the only terrestrial mammal in that predicament," which has incited him to exercise his æsthetic instincts and make that singular secondary decorative use of his respiratory pigment which could serve as an introduction to a consideration of the best part of human conduct. It is an accident that hæmoglobin is red, but it is an accident on which is founded the homœopathic magic of the virtues of red wine and pink pills and all sorts of curious beliefs and practices. Is it possible after all that some of the invertebrates are more emotional than we suppose?

CONFERENCE ON PHYSICALLY DEFECTIVE CHILDREN.—A Conference under the joint auspices of the Central Committee for the Care of Cripples, 10, Berkeley-street, London, W. 1, and the Newcastle Invalid Children's Aid Association, 17, Ellison-place, Newcastle-upon-Tyne, will be held at Newcastle on July 19th. The subjects for discussion will be the treatment and education of physically defective children and the best methods of administration and coördination to procure the same. Programmes will be issued shortly.

Annotations.

"Ne quid nimis."

"BACK-PRESSURE" AND HEART FAILURE.

IN this issue of THE LANCET we print the concluding section of Sir James Mackenzie's important dissertation upon the whole subject of Heart Disease and Pregnancy. These chapters will, we feel sure, have appealed to a wide circle of readers, coming as they do from the pen of one who writes with the authority derived from a lifetime of careful observation at the bedside. For many years Sir James Mackenzie has taken every opportunity of insisting, both by written and spoken words, that the heart muscle is the vital factor in the production of the phenomena of heart failure. The same notion can be found here and there in the writings of an earlier generation, but it appears only sporadically and without insistence. In the main, until recent years, there had been a tendency to ignore the heart muscle, and to focus attention on the heart valves. This undoubtedly resulted from the introduction of the stethoscope—an instrument which Sir James Mackenzie regards as a not unmixed blessing so far as the heart is concerned—for the discovery of cardiac murmurs, and their relation to valves found damaged at the post-mortem examination, led to the conclusion that the embarrassment of the circulation was due to the damaged valves. There followed the gradual evolvement of the back-pressure theory to explain heart failure. It was assumed that the damming back of the blood in the chamber behind the damaged valve—for instance, in the left auricle when the mitral valve is stenosed, caused that chamber to dilate and fail; the consequent congestion of the lungs led to failure of the right ventricle, which in turn brought about failure of the right auricle, tricuspid incompetence, general œdema, and finally failure of the left ventricle.

In his book on "Diseases of the Heart" (third edition, p. 6), Sir James Mackenzie points out that the back-pressure theory did not arise from the careful observation of individual cases passing through the different stages of failure, but from attempts to describe the process by arguing backwards from the evidence present in advanced conditions of failure. He further states that the theory has done much harm to individual patients and has hampered the advance of medical science. It is interesting to note in this connexion that in the second section of the present article, Sir James Mackenzie now considers that back-pressure does play some part in the production of heart failure in certain cases, especially in mitral stenosis. But the theory fails to account for a very large number of cases, and conspicuously in that common group in which, with the onset of an abnormal rhythm such as auricular fibrillation, failure with general congestion is abrupt in its origin. Nor is the new and abnormal rhythm in these cases itself the cause of the failure, for it is by no means uncommon to meet with cases of auricular fibrillation with little evidence of circulatory embarrassment. We are led to the conclusion that the determining factor is the degree of integrity of the heart muscle. The complete story of heart failure is not yet unfolded. The remaining chapters will assuredly be written, and much may be hoped in the future from that method of accurate clinical observation of which Sir James Mackenzie is a past master.

THE DENTISTS BILL.

THE Bill, as amended, remedies the failure of the Dentists Act of 1878 in many directions, though it does not give general satisfaction. We think that the Dentists' Committee may be congratulated on the general moderation of their demands. And having conceded the major claims of the Bill, is it really of much value to have a "special list."

or a special term such as "Dental Practitioner," to distinguish the new-comers from the men at present registered? After all, it is not the profession who have to select the dentist but the general public, and when we allow the 4000 men carrying on practice under the protection of the present Register to be watered by the inrush of some 10,000 unqualified practitioners, how can we expect the public to recognise the distinction afforded by a duplicate list? After all, it is to the Dental Directory rather than to the Register that the small proportion of the public who makes inquiry as to the qualifications of a dentist will go, and there a man's professional record will be fully set out. And even now the 14,000 dentists of the new official list will not suffice for the great mass of the public. Of dentistry more than of any other calling may it be said "the harvest truly is plenteous, but the labourers are few." It is, therefore, to be regretted that the Bill omits or waters down important recommendations such as the provision of maintenance scholarships for one-half of the entrants to the profession in the next five years; a complete scheme of dental inspection and treatment of school children, and children under 5 years, and expectant and nursing mothers; the setting up of a public dental service in populous areas; and finally, the granting to public health authorities of powers in regard to dental disease similar to those contained in regard to tuberculosis in Section 3 of the Public Health (Prevention and Treatment of Disease) Act, 1913. These measures are the positive steps which must be taken if we wish to destroy quack practice. Prohibitions are well as far as they go, but provision is better, and in this respect the Bill before Parliament is lamentably wanting. The Bill has passed the second reading in the House of Lords, and if various interests are affected it is well for all parties to remember that we are living in an age of great reconstruction, and patience as well as boldness is required of us all.

NO NECK.

IT is a constant feature of mammalian anatomy to have seven vertebræ in the neck and seven only; the constancy is almost comic, for the supply is more than adequate for the walrus or dolphin, and much less than adequate for the giraffe. Man may well be content with seven. In a recent issue of *La Presse Médicale* is a description by Dubreuil-Chambardel of a rare condition associated with a developmental defect of the cervical vertebræ. Although medical literature contains many references to an analogous defect in the lumbar region, variations in the number of the cervical vertebræ are much more rarely met with, and have received correspondingly scanty attention. The writer in the paper under notice has collected the published observations relating to 12 cases of "les hommes sans cou" with the idea of presenting a complete clinical picture, the symptoms of which he designates as the syndrome of Klippel-Feil after the two men who first described it in 1912. From the anatomical standpoint the main characteristic of the syndrome is the partial or complete fusion of the cervical vertebræ. It is difficult to distinguish clearly the vertebral bodies in this fused mass—although usually the rudiments of three or four deformed vertebræ may be made out—the atlas and the axis often being so small and indistinguishable in the mass as to appear to be absent altogether. Another characteristic is the presence of a triangular opening on the posterior aspect of the vertebræ which may reach from the cranium to the thoracic region, constituting a true spina bifida. This condition, although not constant, was present in eight of the 12 cited cases. The third anatomical characteristic to which the author draws attention is the displacement upwards of the chest—the "cervical thorax"—owing to atrophy of the cervical column and elevation of the thoracic vertebræ and ribs. The three main clinical signs of the condition are: the absence of the neck, more noticeable from the posterior view; the limitation of head movements, more especially rotary and lateral movements; and the level of the base of the hairy scalp, usually below the biacromial line. To these signs may be added an associated scoliosis, with or without kyphosis, and the lowering of the mammary areolæ together with the elevation of the scapulæ. The ætiology of the dystrophy is obscure, the author preferring not to commit himself to an opinion as to whether the association of spina bifida is post hoc or propter hoc. Finally, the writer discusses the differential diagnosis of the condition, which was mistaken for Pott's disease in five out of the series of 12 cases, and for a simple torticollis in several other cases, in two of which section of the sterno-cleidomastoid was done, without, of course, any effect. The diagnosis rests mainly on the congenital character of the deformity, the absence of pain and swelling, the persistence and painlessness of nodding movements, while lateral and rotary movement is limited or absent, and the abnormally low level of hair growth posteriorly. An X ray photograph, however, settles the diagnosis conclusively. The deformity, which is not incompatible with a long life, appears to be commoner in men than in women, the proportion in the cases cited being 9 to 3.

POST-GRADUATE MEDICAL EDUCATION.

IN January last a Committee was appointed by Dr. Addison, as Minister of Health, to investigate the needs of medical practitioners and other graduates for further education in medicine in London, and to submit proposals for a practicable scheme of post-graduate medical education. The Committee, composed of the following members, Dr. H. J. Cardale, Sir Wilmot Herringham, Sir George Makins, Sir George Newman, Sir Robert Newman, M.P., Sir Edward Penton, Sir E. Cooper Perry, Mr. J. Dill Russell, and Dr. T. W. Shore, with Lord Athlone as chairman, has just issued its report.[1] The chief recommendation made is the establishment of a Central Post-Graduate Hospital and School to be devoted solely to post-graduate work. The hospital should contain at least 300 beds and its equipment should be complete and modern, and a fully developed out-patient department would be an essential. The allotment of beds is suggested as follows: medical 100, surgical 100, ophthalmology 12, skin diseases 12, gynæcology 24, children's diseases 12, venereal diseases 6, neurology 12, laryngo-oto-rhinology 12, observation and septic cases 12. Associated with this Central Hospital and School would be the great special hospitals of the metropolis. It is suggested that one of the existing under-graduate schools might be converted into such a centre, and the building of a new hospital for this special purpose is not recommended. The institution of a central office to link up post-graduate study in the United Kingdom with that of the continent of Europe and America is suggested. This central office should be in the charge of a whole-time principal officer and its committee of management should be responsible for the organisation of the system as a whole. Social facilities in the shape of reading rooms, a restaurant, and a library of periodicals should be attached to this central office, and a hostel for the convenience of doctors attending the courses from a distance would also, in the opinion of the Committee, be a desirable addition.

Another important recommendation is the establishment of an institute of State medicine whereat public health post-graduate work should be concentrated. Such an institute might be under the administration of the University of London, in a position analogous to that held by the Institute of Historical Research, and would provide instruction in public health, forensic medicine, toxicology, and industrial medicine to students from the United Kingdom, from overseas, and from foreign countries. The whole scheme as outlined in the report would involve an annual charge of approximately £28,000. As constituent parts of the University of London, the school and institute would be eligible for inclusion in the list of institutions subsidised by the Treasury through the University Grants Committee. Fees from students would raise a certain amount, and from whatever source the balance, if any, is to be procured, it is not proposed to ask for support from local rates. These are the main conclusions of the Committee, which includes in its report some account of the history of the attempts to procure post-graduate facilities in London, with special reference to the efforts of Sir Jonathan Hutchinson and, more recently, of the Fellowship of Medicine. We trust that prompt action will be taken on the lines suggested by the Committee.

---

[1] Report of the Post-Graduate Medical Committee. H.M. Stationery Office. 8d.

INJECTION OF ANTITOXIC SERUM AND SUDDEN DEATH.

FROM time to time cases of sudden death following the injection of antitoxic serum are recorded, sometimes even in healthy persons to whom the serum is given for prophylaxis. The prevalent view is that these distressing tragedies are due to anaphylaxis. In the *Journal of the American Medical Association* Dr. J. H. Lewis has advanced very cogently a new explanation. He points out that it should be impossible to produce death by subcutaneous injection of serum in ordinary doses. To produce acute anaphylactic death experimentally the antigen must get into the circulation rapidly. Paul Lewis found that from 6 to 10 c.cm. of serum injected into a sensitised guinea-pig (the most sensitive animal to anaphylaxis known) did not kill; from 12 to 20 c.cm. were necessary. But taking 6 c.cm. as the dose that will kill a 250 gm. guinea-pig, nearly two litres would be necessary to kill a 70 kg. man, if he were as sensitive as the guinea-pig, which he is believed not to be. Practically all the fatal cases are similar. A few minutes after injection the patient is seized with intense dyspnœa, followed by œdema and urticaria. The respiration ceases, but the heart continues to beat and death occurs within ten minutes. The sooner the reaction appears the more intense it is. These cases are inconsistent with the rate of absorption of serum from the subcutaneous tissue. This has been shown experimentally to be very slow by testing by complement-fixation the time of appearance in the circulation of horse serum in an animal subcutaneously injected. In a dog, injected with 10 c.cm., serum was first detected in the circulation 1½ hours after injection and was found present for 24 hours. To account for the presence in the circulation of serum in sufficient quantity to prove fatal in a few minutes, Dr. Lewis suggests that the injection was accidentally made into a vein. The subcutaneous tissue contains numerous vessels of good size and it is possible for the point of the needle to enter one. Then only a small amount of serum could be fatal to a sensitised person. A case of fatal intravenous injection of only one minim of horse serum into a man the subject of horse asthma has been recorded. The possibility of accidental intravenous injection is supported by experience of subcutaneous injection of oils and fat. Moller reported fat embolism 43 times in 315 patients injected subcutaneously with oily substances 3835 times. Febriger recorded a death following subcutaneous injections of olive oil in a patient suffering from stricture of the œsophagus. He developed hemiplegia and the necropsy showed fat emboli all over the body. Embolism after paraffin injections has also been described. A point which Dr. Lewis does not make is that the danger of injecting into a vein in the case of hypodermic injection of drugs has long been recognised. To avoid the danger of intravenous injection, Dr. Lewis recommends care before injecting to ascertain whether a blood-vessel has been injured. Aspiration should be performed to see whether blood can be drawn into the syringe. Another way in which serum may rapidly enter the circulation after hypodermic injection is on massaging the swelling produced, which Dr. Lewis says is a common practice; but whatever be done in America we have not heard of the practice in this country. He found that a dose of serum not big enough to kill a sensitised guinea-pig quickly proved fatal when the site of injection was massaged. This should be warning against the practice.

THE CORONERS (REMUNERATION) BILL.

A BILL has been amended in Standing Committee and read a third time in the House of Commons which has for its object the raising of the emoluments of coroners, who are now paid at a rate not changed since 1887. In view of present conditions, and of the importance and responsibility of the coroner's office, it would appear to be in the public interest that the remuneration offered should be such as to attract well-qualified men, and the qualifications necessary for a coroner are a knowledge of medicine and of law. In other words, the ideal coroner should have undergone the training and seen something of the practice of two learned professions. Nevertheless there were several members of the House of Commons who were evidently opposed to the Bill. One of these expressed disapproval of the fact that it was moved by a Member of Parliament, Sir T. Bramsdon, who was himself a coroner, and he contended that whether this was within the strict letter of the orders of the House, or not, it was utterly wrong. As a matter of fact, the Speaker had been consulted by Sir T. Bramsdon, and had ruled that his association with the Bill was perfectly in order. We fail to see that it can be "utterly wrong," as a matter of general principle, for a Member of Parliament, who has in some sense a personal interest in a particular piece of legislation, to abstain from furthering it or from impeding it. It is true that Members of Parliament are returned by their constituencies and that they have to consider the interests of their constituencies as well as those of the country at large. They are, however, if they are members of a particular profession or trade, experts with regard to it, and if without any concealment they take part in legislation directly or indirectly affecting it, their fellow members are well able to determine whether they act honestly in the general interest, or whether professional feeling is corrupting their judgments in a matter of public policy. There were members of the bar among the adverse critics of Sir T. Bramsdon, but it has never been urged that barristers should have nothing to do with legislation which provides remunerative posts for their profession. Nor has any consideration of the fact of their being personally interested prevented members of the House of Commons from providing themselves with salaries.

CHANCRE OF THE GUM.

IN a review of the literature of the subject, including the description of a personal case, Dr. Joseph Victor Klauder,[1] Assistant Professor of Dermatology and Syphilology in the Graduate School of the University of Pennsylvania, remarks that chancre of the gum is one of the rarest of extragenital chancres. Scheuer, in his work on "Syphilis of the Innocent," published in 1910, out of a total of 14,590 extragenital chancres recorded up to that date, states that only 97, or 0·66 per cent., were gum chancres. Since the appearance of Scheuer's book 15 cases of chancre of the gum have been reported up to 1919, making a total of 112 cases. The greater frequency of buccal chancres in some countries than in others is attributed by Dr. Klauder to the manner of eating and customs of different races and to racial customs of nursing and feeding children, and not, as might be supposed, to perversion of the sexual act. The chief source of infection is accidental contamination by various objects, especially toothbrushes, toothpicks, and dental instruments. In all the reported cases the lesion on the gum has been single, though in one of Fournier's cases there was an associated chancre of the hard palate, and in Frossard's case a lingual chancre as well. The anterior part of the gum is involved almost exclusively, and the upper gum is more frequently affected than the lower, the usual site of the chancre being opposite one or more incisor teeth, sometimes the median incisors but more frequently the left lateral. There are usually two types of chancre of the gums. The first or erosive type varies in size from that of a split pea to that of an almond, and is sharply demarcated from the surrounding tissue. The surface is smooth and of a carmine colour. Although in exceptional cases the lesion may remain unchanged, it usually becomes infected, the surface being covered with a false membrane and the centre showing ulceration and necrosis. The second type of gum chancre appears from the first as a sharply circumscribed ulcer of variable size and shape. Infection of the periosteum not infrequently occurs, the symptoms of which make the diagnosis more difficult. The conditions from which chancre of the gum is to be distinguished are inflammation and ulceration due to various causes, as well as tumours such as fibroma, epithelioma, and sarcoma. The early appearance and extreme degree of the adenopathy are characteristic of chancre, and the diagnosis is confirmed by the Wassermann reaction and dark-field examination.

THE EXAMINATION OF GASTRIC AND DUODENAL CONTENTS.

THE introduction of fractional methods of gastric analysis has given a fresh impetus to the study of the secretions of the alimentary canal. Few gastro-enterologists are now content with the information given by analysis of a test-meal which has been withdrawn after an hour's gastric digestion. The main shortcoming of the old method was the indefinite indication which it supplied as to the actual degree of pyloric obstruction and gastric stasis present in any particular case. At the same time the technical difficulties of fractional analysis have delayed its universal adoption, and it is accordingly of interest to find the original devisers of the fractional technique now devoting especial attention to the examination of the "resting-juice," or "gastric residuum," as a means of clinical diagnosis. This has been the form of gastric analysis advocated for a considerable time by many of the French physicians, notably by Loeper, Pron, and Labbé, and there can be little doubt that it frequently yields information of the utmost value. In their latest communication,[1] Rehfuss and his co-workers in Philadelphia draw special attention to the conclusions which may be derived from knowledge of the volume of the fasting stomach content, and to the significance of the presence of food retention, altered acidity, pus, blood, and mucus. Especially do they point out the importance of septic conditions of the nose and throat as sources of the muco-pus frequently found in the stomach. The extraction and analysis of duodenal contents must necessarily present far greater difficulties than those attending gastric investigation; but in this field also advances continue to be made. Following the technique of Einhorn, an inquiry into the whole subject has recently been made by Mauban, of Vichy; his work[2] deals chiefly with technical methods for the passage of the duodenal tube, the quantitative estimation of the ferments and other constituents of the duodenal secretions, &c. It is to be expected that these and similar methods will, during the coming decade, yield information which will help to dispel the obscurity which at present veils so many of the problems of gastro-intestinal disease.

INDUSTRIAL CATARACT.

IMPORTANT evidence as to the causation of certain forms of cataract will be found in the May issue of the *British Journal of Ophthalmology*. The observation that glass-workers in this country were especially prone to the disease was first made by Mr. W. Robinson, of Sunderland, who published papers on the subject in 1903 and 1907. Afterwards bottle-makers' cataract was placed by the Home Office upon the schedule of diseases under the Workmen's Compensation Act. At the same time a committee of the Royal Society was appointed to investigate the causation of the disease, and researches were conducted upon the absorption of various radiations by the media of the eye. In 1915 a paper was published in the Proceedings of the Royal Society by Prof. A. V. Hill and Dr. G. Hartridge tending to prove that the heat factor was of primary importance, but up till that date, with the exception of cases occurring among the glass-makers, there was a lack of clinical evidence to support that view. This evidence, however, has since been forthcoming. Some cases have been published by Mr. B. Cridland, of Wolverhampton, in which men who work at iron-smelting furnaces have developed a form of cataract identical with that observed among the glass-workers. Mr. St. Clair Roberts, of Dudley, has collected 25 similar cases among the chain-makers, men who spend the whole of the working day either gazing into the fire to judge when the links are hot enough to weld, or at the white hot metal while hammering it on the anvil. Still more remarkable evidence is supplied by Mr. James J. Healy, who, after having had the opportunity of seeing the cases among the bottle-makers of Sunderland, has made special investigations among the tinplate millmen of Llanelly. "The work is unusually heavy," he says, "and the heat is very great, so much so that a person unaccustomed to the work could not stand in the centre of a mill for longer than about five minutes without feeling somewhat overcome." "All the men in the mills are exposed to infra-red rays from the red hot tinplates . . . the ultra-violet rays are negligible." Cases occurring in men who had been working under 15 years in the mill were rare, but of 354 men of 35 years or over, who had been at work in the mill for as much as 15 years, 144 were found to have lenticular opacities, which could be detected without dilatation of the pupils. On the face of it the evidence appears to be irrefutable that continuous exposure to excessive heat over a long period is an efficient cause of cataract. Prevention is not easy, for although, as Mr. Healy remarks, the wearing of suitably prepared triplex standardised goggles would keep back the heat rays from entering the eyes, some additional preparation would have to be found to prevent the otherwise inevitable collection of moisture and dust on the glasses. It is to be hoped that this may be done before long. Meantime it seems very unfair that although glass-workers are entitled to receive compensation by law for the development of cataract, other workers whose eyes are exposed to excessive heat are not. To quote from the *British Journal of Ophthalmology*: "The evidence adduced by Messrs. Cridland, Roberts, and Healy is so conclusive that there is every reason to hope that the Home Office will take steps to remove this anomaly." The Glass-workers' Cataract Committee of the Royal Society, we understand, are taking steps to this end.

CONGENITAL ATRESIA OF THE ŒSOPHAGUS.

ACCORDING to Dr. I. Seth Hirsch,[1] director of the Roentgen Ray Department, Bellevue Hospital, New York, who reports two illustrative cases, 146 verified cases of congenital atresia of the œsophagus have been reported up to July 1st, 1920, the first having been observed by Thomas Gibson in 1696. The commonest type which is met with in 70 per cent. of the cases is a blind upper sac measuring from 1 to 9 cm. in length with a lower sac opening into the trachea at or above the bifurcation. The two portions may or may not be connected by a thin strand of tissue composed of muscle fibre or fibrous tissue. Associated anomalies are frequent, being present in 59 out of 94 cases. The commonest is atresia ani, which was present in 24 cases. The period of survival which was noted in 120 cases has ranged from 1 to 14 days, five of the infants being stillborn and 15 dying on the first day of life. As regards the pathogenesis it is now generally conceded that the anomaly is due to a developmental error rather than to an inflammatory process as was once supposed, the condition being due to failure of closure of the tracheo-œsophageal septum.

THE I.M.S. DINNER.

THE annual dinner of the Indian Medical Service, held on June 15th at the Trocadero Restaurant, is a domestic gathering at which the Editor of the *British Medical Journal* and the Editor of *The Lancet*, and they alone, are invited to share the salt. Leave is scarce in the Service at present and passages still scarcer, and it therefore comes about that the dinner is representative of those who have seen ten years or more of the official practice of medicine in a country which contains a sprinkling of Europeans and 450 millions of other races. In the nature of things there is no possibility of a similar gathering in India itself. Hence the occasion is one of unique importance and the time that might have been wasted upon formal toasts and set speeches is free for the informal discussion of domestic policy. No one present asserted that the Medical Service is now a great reconciling influence in Indian life, for no one doubted it; nor was any hesitation felt in mentioning the colour difficulty, for senior native officers were present as an integral part of the Service. All agreed that as long as Britain was charged with the Government of India, so long would British medicine find a worthy place there and nothing but the best possible service could be offered. Sir Dawson Williams in a few wise words spoke of the support given to the Indian Medical Service in the past by the medical press of this country and of their community of interest for the future. To say more might be to transgress the sacred law of hospitality. But we should like to commend the Dinner Fund to those members of the Service who do not yet subscribe to it.

SIR THOMAS WRIGHTSON.

THE death of Sir Thomas Wrightson, at the age of 82, removes a figure notable alike in science and industry. Born near Darlington in 1839, Wrightson completed his education at King's College, London, and took up engineering as his profession, serving his articles with his cousin, Lord Armstrong, at Elswick. After a period of civil engineering work at Westminster, he took employment at the Teesdale Ironworks of Messrs. Head, Ashby and Co., later joining the firm, which then became Head, Wrightson and Co., Ltd. For many years he was vice-chairman, and later chairman, of this great business, being also a director of other companies and a prominent figure in the public life of the Stockton district. His political career was not marked with the uniform success which attended him in other directions, but his services won him a baronetcy in 1900. Wrightson's great contribution to physiology and physics, his "Enquiry into the Analytical Mechanism of the Internal Ear," was published in 1918,[1] when he was in his 78th year. In this work were combined the results of many years of study of aerial wave-form, with an engineer's survey of the cochlea considered as a machine. The comparative anatomy of the cochlea formed the subject of a luminous appendix by Prof. Arthur Keith; by means of his own ingenious "ohmograph" Wrightson had recorded a large number of compound sound curves of varying complexity, which he analysed by application of the "four stimulus" theory—i.e., the theory that a sound wave is a pressure variation implying a stimulus in hearing of four phases of the curve at maximum and minimum, and at the crossing of the zero lines, at each of which points the direction of change is reversed. Briefly, the authors showed the cochlea to be a mechanism capable of registering every complexity of the compounded wave and of passing it on to the sensorium in accurate record as nerve impulses, the final process of appreciation of these impulses (simple or compound) being, of course, central. Wrightson's work therefore gave to science an intelligible account of the genesis and nature of the peripheral stimulus concerned in the sense of hearing.

CONGRESS OF MEDICAL HISTORY.

A CONGRESS on the history of medicine, initiated by Prof. Domenico Baduzzi of Siena, was held at Rome from Oct. 11th-14th, 1912, when the agenda paper included addresses on prehistoric medicine and mediæval anatomy. Last year a congress was summoned at Antwerp and next week, from July 1st to 6th, the Second Congrès d'Histoire de la Médecine will be held in Paris under the patronage of the Minister of Public Instruction and on the initiative of the Société Française d'Histoire de la Médecine. Prof. E. Jeanselme and Prof. W. Menetrier will preside at the meetings, which begin at 9 A.M. on July 1st in the historical museum of the Faculty of Medicine. An "exposition rétrospective médicale" is being put together to include books, manuscripts, engravings, statuettes, instruments, or other objects of historical value. A number of visits and excursions have been arranged to places of historical interest. The general secretary of the Congress is Dr. Laignel-Lavastine, 12 bis, place de Laborde, Paris.

THE annual meeting of the National Council for Combating Venereal Diseases will be held next Tuesday, June 28th, in the Morley Hall, Hanover-square, at 4.15 P.M. The annual report, the draft of which is now being settled, brings the proceedings up to May 31st.

WE are glad to print in full on page 1377 an interim report of the X Ray and Radium Protection Committee, for it is well that safeguards and precautions, wherever they have been found useful, should receive immediate and wide publicity. London is fortunate in having a sufficient number of recognised experts to constitute a representative committee which can meet frequently to confer and compare notes. Distance alone has stood in the way of choosing the committee from other centres of radiology. Liverpool and Manchester have been well to the fore in precautionary measures, and the London committee has profited by their experience.

THE last of the series of lectures delivered by authorities on different aspects of pathological research in its relation to medicine at the Institute of Pathology and Research, St. Mary's Hospital, was given on June 16th by Prof. W. Bulloch, F.R.S. His subject was the Use and Abuse of Scientific Medical Literature, and among entertaining anecdotes and criticism, destructive and constructive, of current medical journals Prof. Bulloch found opportunities to plead for a reduction in the mass of work published and an improvement in its quality. The course of lectures has been much appreciated by large and representative audiences.

THE SEMON LECTURE.—The Semon Lecture, a foundation of the University of London, will be delivered on Tuesday, July 5th, at 5 P.M., by Dr. Jobson Horne, President of the Laryngological Section of the Royal Society of Medicine, in the house of the Society.

MODERN ARTIFICIAL LIMBS.

THE WORK OF THE ARM-TRAINING CENTRE AT ROEHAMPTON.

BY C. JENNINGS MARSHALL, M.D., M.S. LOND.,
ASSISTANT SURGEON AND JUNIOR ORTHOPÆDIC SURGEON TO KING'S COLLEGE HOSPITAL.

WHILE the function of a lost lower limb has for centuries been capable of replacement with a fair degree of success, the achievements with the arm have remained on a very much less satisfactory basis—occasionally, as with the immortal Captain Cuttle, a lost hand has been replaced by some elementary instrument, but any instance in which even the simplest function has been restored has appeared as something remarkable. The rule has been that a lost arm has meant a sleeve as empty as Nelson's.

The recent advances in the structure of the artificial limb—advances confined to a mere score of years—have attracted a great deal of attention of late, particularly in the lay press. The publicity thus gained has, of course, had some beneficial effects, notably in inspiring confidence, both among the general public and those directly or indirectly concerned, in the means that are being taken to repair the most distressing wreckage of the war. One fact, however, does not seem to have emerged in its true perspective, some accounts read almost as if the limb were in itself endowed with a mysterious motive power, readily attached and placed under the control of the amputee. It would appear as if the fitting of the limb in itself restored the function that had been lost. The results must have been particularly deplorable in cases where the sufferer acquired such ideas, was fitted with the limb (perhaps not quite so efficient as the most modern, but still capable of very good work), and has gone forth expecting the advertised miracle. Disillusionment must come, demoralisation, despair, and resentment, the suspicion that the best limb has not been given and that there has been shabby, parsimonious dealing. The limb has been discarded and the man who should once more have become a self-reliant, self-supporting member of the community, turns into a drifting, discontented, and demoralised unit. This is history in hundreds of instances—history that happily is not only no longer being made, but is also being unmade.

It is history that need never have been made at all, for fairly obvious reasons. Comparatively little trouble is necessary to attain a decent degree of ease and function in the case of the lower limb prosthesis, for weight-bearing and locomotion are relatively simple questions; but to attach to a stump something that will handle, hold, swing, lift, and half a hundred other things is very different. The importance of instruction in the use of the new complicated appliance must be clear.

Necessity of Education in Use of Artificial Arm.

The fact that up to about three years ago some three-quarters of the men who had lost arms in the war had discarded their prosthesis as useless or as too much trouble cannot be more than slightly attributable to the defects of the limbs themselves, although considerable progress has been made since then in the construction of artificial limbs.

The small classes of case may first be eliminated—those of surgical unfitness to wear a limb, and the somewhat larger number of those with inefficient and unsuitable limbs. The remedies here are obvious. The remainder, the great majority, are cases where a man, physically capable, has simply not been educated in the use of a mechanically efficient limb. It is particularly necessary to note that such education must not be merely technical. The recovery of loss of function depends to a very great degree on the mentality of the patient, and the old admonition to "treat the patient as well as the disease" is nowhere more applicable than in the case we have under consideration; there is a liability to neglect the mental make-up of organic disease—(apart from which fact one has the suspicion that the phrase is made responsible for a great deal of humbug!)

In war injuries we have to deal with three kinds of mental attitude. First comes what can be termed the sympathetic or coöperative type—those in this class will actively aid and participate in the attempts at restoration. Next is the antagonistic—those who do not wish for recovery, do not believe that it can be attained, and suspect and resist the treatment given (this attitude may be conscious, subconscious, or both). The third and worst group is that of entire indifference to recovery or non-recovery—the apathetic.

It will be obvious that to obtain results in the first group will be a comparatively simple matter if reasonable attention is given and the physical disability is at all capable of being surmounted. In the second there will be the necessity for the most open, frank treatment, the willingness to examine all alleged grievances, to reason, and to persuade. In the third direct argument and persuasion may be of use, but the best stimulant by far of the desired interest is the "atmosphere of recovery."

The work of the arm-training centre at Roehampton is an object-lesson in successful methods of overcoming such problems.

The Modern Artificial Limb.

Before giving a description of this work it will be useful to interpose a brief account of the modern artificial arm, although naturally it will be impossible to go into the details of the various types. This is all the easier inasmuch as, while there is a wide range of arms officially sanctioned by the Ministry for fitting, it may be said that there is a tendency to standardisation of principles of construction. It must not be thought that this means that the official policy is towards the stereotyped—on the contrary, it is strongly progressive. Suggestions for improvements are welcomed, and are sure to receive the fullest possible consideration; every facility is given to inventors, and inventions are constantly being brought forward by armless men—who, indeed, have been almost entirely responsible for the efficiency of the modern arm. New improvements are constantly and promptly added to the official list, and become available to all armless pensioners. One actually witnessed the encouraging reception given to an inventor by the Chief Instructor, himself an armless ex-officer and inventor; the appliance was appraised, suggestions were offered for further slight improvements, and a full account of the procedure to obtain recognition was given. The manufacture of limbs entirely by private firms further prevents stagnation (it is to be noted that the industry provides constant employment for a large number of limbless men).

Function of the Artificial Arm.

The complex functions of the upper limb can, of course, be reproduced only to a limited extent by any prosthesis. In particular, it is only the simpler of the hand movements that can be replaced. The joints will be considered seriatim; joints surgically preserved will obviously retain their function if adequate leverage and articulating stump be provided beyond them for the artificial limb.

1. *Shoulder-joint.*—The artificial shoulder remains passive and may permit abduction, flexion, and extension, or all of these. Rotation is not needed, being supplied at the "wrist." The limb swings at this joint actuated by power transmitted through the objects gripped from the other limb, which is holding the object at the same time. Nevertheless, anterior and posterior movements are to some extent produced when the elbow is actively moved by transmission cords.

2. *Elbow-joint.*—A variety of possibilities exist for the elbow-joint. It may be simply adjustable mechanically by the other hand; there are numerous forms of hinges

and catches permitting fixation at any desired angle. In other cases an active movement of flexion terminates in an automatic lock released either by another transmitted movement or by the sound hand. Again it is permitted in other instances to let the elbow swing freely by grip-transmitted power, as at the shoulder.

3. *Pronation and Supination.*—In no artificial limb does the forearm stump activate voluntary rotation—i.e., the stump acts merely as a lever. It seems to have proved impracticable so far to utilise the freedom of the radius, a fact which emphasises the difficulties in the way of the making of artificial limbs, for it might appear on the surface that this could fairly easily be done. In many limbs the "wrist" is fixed in the mid-prone-supine position; in some it is adjustable by the sound hand, but in the majority the appliance attached to the forearm is free to rotate at the wrist, being controlled by the grip of the sound side—as, for instance, where both hands hold a spade. In a few, however, rotation with locking by active movement is provided.

4. *Wrist Movements.*—Here again the joint, where a "hand" is fitted, may be either fixed in moderate extension, adjustable by the sound hand in the desired position in some cases, or be capable of movement by active, transmitted power, a mechanical lock operating at the end of such a movement where desired. In most instances the forearm terminates for working purposes in a tool whose attachment may be either "free wheel," adjustable, or fixed.

Photographs showing the very active rôle of which the artificial limb is capable. The standard "harness" is not being worn.

5. *The Grip.*—For æsthetic purposes it is desirable that the limb should terminate in some semblance of a gloved hand. The dress arm always provides this, and in some forms of limb a hand is fitted which is capable of performing light or even moderately heavy work. In most instances, as already stated, a tool is attached where moderate or heavy work is to be performed. As regards the production of the grip sustained hold on an object is always obtained mechanically—e.g., by springs, lock, or rack. Release of the grip may be by an active movement as in most forms of "hand" or by a device operated by the sound hand. Spring and release attachments are also fitted for the thumb on the same principles.

6. *Tools.*—It is in the appliances or tools attached to arms that probably the greatest advance has recently been made; of them again there is infinite variety, and one was greatly impressed by their ingenuity. Some of their qualities were particularly striking—strength, lightness, wide range of usefulness, and above all, ready and quick interchangeability. As an example might be quoted the "Mechanical C Hook," in whose invention the Arm Training School played a great part. This provides for gripping large or small objects, loose hold of large objects, and pressing down either large or small objects. The grip is released by transmitted power and is maintained by a spring. This is relatively a very wide range for such appliances. It might be stated here that most of the modern tools are the direct outcome of the work of the School at Roehampton, a fact which speaks volumes for the way in which its task is carried out.

With regard to the structure of the limb, those officially sanctioned show a great variety in material. Wood, leather, and metal, fibre and metal, duralumin, are most commonly used; a new substance, certalmid, is being more and more used in the making of buckets, being akin in its range of applicability to celluloid-acetone, but superior in cheapness, absolute non-inflammability, rigidity, and ease of application. This material is the result of much patient labour in the Ministry Research Laboratory attached to the hospital. One ventures to predict for it a great field of usefulness in orthopædic work.

Production of Movements in Artificial Arms.

It is perhaps necessary to point out that the armless man has to educate his remaining arm as a right arm—e.g., a left-handed amputee has to educate a remaining right arm to replace the function of the lost left arm.

Voluntary Movements.—These are produced on a very simple principle. The prosthesis is attached to the body firstly by a moulded segment appropriate to the site of amputation and secondly by a standard harness. This is made of a series of bands of broad webbing fixed to the segment applied to the body, converging somewhat usually at the middle of the back, and then expanding again to embrace the root of the opposite limb, the pressure being taken chiefly by the anterior axillary wall and the clavicle. No straps pass, in the most modern harnesses, in front of the chest—this permits a surprising degree of freedom of shoulder movement, and the harness and limb can be attached in a very few seconds and with great ease.

Motive Power.—From the sound side, which acts as the fixed (not as commonly supposed, the activating) point, two or three leather bands or Bowden wires pass in various relations to the affected shoulder through pulleys and thence to appropriate points of attachment on the artificial limb; leaving no slack. It follows then that if the sound shoulder remains fixed and the cord be put on tension by a movement of the affected shoulder, a pull will be transmitted to the insertion of the cord or wire. Roughly speaking, vertical, anterior, and posterior movements of the shoulder are available for transmutation into energy to reproduce the active functions of the limb. In addition others may be utilised—flexion of the humeral stump, even flexion of the elbow.

The function of the artificial arm will therefore be seen to depend on the following: active movements, rarely more than three in number, are derived from certain educated actions of the shoulder muscles; they are employed in altering the position or attitude of a part of the limb, or in releasing springs or catches; very uncommonly are they used in a sustained effort; springs, &c., are used for maintaining hold on an object; joints other than those selected for active movement may be either fixed, adjustable to various positions by the sound hand, or left freely mobile.

We are now in a position to see, first, the obvious need of the amputee for training, and the utter futility of sending him forth without such instruction in the use of this really elaborate tool. Further, it is clear that great benefit will be derived from the advice of those experienced in the selection of limbs for particular occupations; there is a great deal in the actual selection of the limb and of the tools. The staff at the limbless hospital possess unique experience in such matters, and it would be the greatest pity were any policy of short-sighted economy to disperse and waste it.

Procedure at the Training Centre.

We can now appreciate the way in which the armless man is dealt with at Roehampton. He is admitted for a while as an in-patient at the limbless hospital in beautiful and healthy surroundings. He mingles with numbers of others with the same kind of disablement, hears them talk of their progress, sees what they can do. He begins to understand that restoration of function is taken for granted, as a thing beyond doubt. He is able to go freely anywhere, seeing armless men at work—digging, hoeing, using a pitchfork, wheeling a barrow even up an acute slope, swinging heavy hammers in driving for instance a pile—and doing all these things without effort or discomfort. He sees that the limb is no mere toy, but a very practical and strong working proposition. He will find that even a very high arm amputation is no bar to an efficient prosthesis; he may see a man disarticulated at the right shoulder, but doing all the above things. This man habitually does gardening solidly for eight hours a day, is no more tired than he used to be before the war, and finds practically no limit to his usefulness. A visit to the workshops will show him all branches of carpentry in progress; there are fellow armless men using plane, hammer, spokeshave, chisel, and the like. He will see that the work can be done cleanly and quickly. He finds that delicate work, too, can be done in spite of the loss of an arm. He begins to compare notes with the workers as to site of amputation, and as to individual experiences with different types of arms. He forms an opinion as to the limb that will be most useful in the occupation he proposes to adopt. With all this at the back of his mind he comes before the medical officer, who after a discussion of the case, and consideration of the surgical aspect, gives instruction for fitting. The man is offered in every case a choice or a large say in the ultimate selection of the limb, for surgically two or three limbs may be applicable; the advice of the staff is always available if he is in the slightest doubt as to which limb to select. Similarly, the tools attached to the limb are decided upon. The benefits of such a system will be apparent, for its great assumption is that the patient is treated throughout as a responsible and free agent. Fitting having been completed (this may take a considerable while for a cast of the stump has to be obtained as a preliminary to the making of a perfectly fitting bucket) the man begins his training. First, a short course of instruction is given in the elementary principles of carpentry, and then the man proceeds to work from simple to more and more complicated actions. It must be understood that the teaching of carpentry is undertaken merely as a means of instruction in the use of the limb, as is also the use of the spade, hammer, hoe, wheelbarrow, and the like. Each involves the learning of a different kind of action, and is studied for this purpose alone. It might be pointed out, however, that many men, both skilled and otherwise, have, as a result of their training at the centre, decided to adopt woodwork, metal work, and the other things used as methods of instruction as their means of gaining a livelihood. In such cases, after the period of arm-training, the man goes to the schools of the Ministry of Labour for a course of technical instruction. Many have thus come into a better status in the labour market than they enjoyed before the loss of the arm.

It is not long, as a rule, before the man begins to take a keen interest in his progress and to compete healthily against those starting with him in the use of the limb. He will become often inordinately proud of some little trick that no one else seems to have acquired. Practice with the limb needs no urging, and it is remarkable to note that the majority of men show a very complete degree of proficiency in from two to three weeks.

While most of the men have a chief preoccupation—their means of livelihood—and pay most attention to the factors bearing on this, there is another and most heartening aspect of the centre. This is in the world of sport and play. It will not be long before the athlete will find that there is no need for the armless man to forgo the pleasures he formerly derived from sport. He can see men who handle a cricket bat with the best, drive a golf ball, and play billiards—instances could easily be multiplied. Perhaps the most interesting of all was the man who fiddled, bowing with a limb fitted high in the arm. Nothing could be more stimulating than to learn that active participation in games is still open—the arm is gone, but the man can still work and play!

This, then, is the atmosphere which envelopes the armless man from the time of his entrance to the hospital. Most of the difficulties that stand in the way of the utmost possible recovery of function are met and conquered by it. While this applies chiefly to the cases newly becoming fit for a limb, it must be remembered that these are still much the largest proportion of the men in the hospital. There is, of course, a big out-patient attendance comprising cases with stump complications, and those requiring repairs or alterations in the artificial limb.

With regard to results, it remains to record an investigation carried out by Colonel MacLeod, medical superintendent, with a view to finding out to what extent the modern artificial limb was satisfactory. Four hundred and fourteen consecutive cases were questioned, the men were invited to make criticisms without reserve, and all such complaints were thoroughly investigated. It was found that of these 414 only 34 were not in good permanent employment, and that in almost every case of criticism the complaints were due to remediable causes in connexion largely with further changes in the stump since fitting.

The Research Laboratory.

This account of the work of the training centre would be very incomplete without a reference to the Research Laboratory attached to the hospital for the purpose of investigating the problems that constantly crop up with regard to the function, manufacture, and details of construction of artificial limbs. Here, again, each difficulty is squarely faced, and there is no rest until some solution is reached. As an instance of the resources of the department, one quotes the use of the Ultrarapid Kinematograph in the analysis of the relative movements of the lower limb and of the phases of the flexion of the knee in walking; a considerable improvement in the gait in thigh amputations has resulted from this investigation. Reference has already been made to certalmid, the valuable qualities of which material were clearly demonstrated.

The whole hospital gives one the impression of an institution strikingly akin to the orthopædic workshop, in which there is a "live" staff, thoroughly experienced in the work of which each member does his utmost to get results, leaving no factor neglected in order to make good as far as possible the disability of the limbless.

ROYAL SOCIETY OF MEDICINE.—The recently established Gold Medal of the Society was awarded to Sir Almroth Wright on Nov. 11th last when he delivered an address, but as it was not possible to have the medal ready for presentation it will be presented to him at the annual general meeting on Wednesday, July 6th, at 5 o'clock.

The meeting of the Dermatological Section in July will not take place.

X RAY AND RADIUM PROTECTION COMMITTEE.

A PRELIMINARY REPORT.

THE X Ray and Radium Protection Committee, representing the various radiological and other scientific bodies with their headquarters in the metropolis, after deliberating for some weeks, has issued a preliminary and admittedly tentative report. The document states present knowledge in regard to equipment, ventilation, and working conditions of X ray and radium departments, and undoubtedly there is a constant demand for guidance, both from individuals and institutions, upon such points.

The preliminary part of its work, the Committee states, will lead up to more extensive objects, entailing research, and offers of personal or other assistance are invited by the Committee and should be sent to the hon. secretaries, from whom the preliminary document may be had on application.

PRELIMINARY REPORT.

Introduction.

The danger of over-exposure to X rays and radium can be avoided by the provision of efficient protection and suitable working conditions. The known effects on the operator to be guarded against are: (1) Visible injuries to the superficial tissues which may result in permanent damage. (2) Derangements of internal organs and changes in the blood. These are especially important, as their early manifestation is often unrecognised.

General Recommendations.

It is the duty of those in charge of X ray and radium departments to ensure efficient protection and suitable working conditions for the personnel. The following precautions are recommended: (1) Not more than seven working hours a day. (2) Sundays and two half-days off duty each week, to be spent as much as possible out of doors. (3) An annual holiday of one month or two separate fortnights. Sisters and nurses, employed as whole-time workers in X ray and radium departments, should not be called upon for any other hospital service.

Protective Measures.

It cannot be insisted upon too strongly that a primary precaution in all X ray work is to surround the X ray bulb itself as completely as possible with adequate protective material, except for an aperture as small as possible for the work in hand.

The protective measures recommended are dealt with under the following sections: (I.) X rays for diagnostic purposes. (II.) X rays for superficial therapy. (III.) X rays for deep therapy. (IV.) X rays for industrial and research purposes. (V.) Electrical precautions in X ray departments. (VI.) Ventilation of X ray departments. (VII.) Radium therapy.

It must be clearly understood that the protective measures recommended for these various purposes are not necessarily interchangeable; for instance, to use for deep therapy the measures intended for superficial therapy would probably subject the worker to serious injury.

(I.) X Rays for Diagnostic Purposes.

1. *Screen examinations.*—(*a*) The X ray bulb to be enclosed as completely as possible with protective material equivalent to not less than 2 mm. of lead. The material of the diaphragm to be equivalent to not less than 2 mm. of lead. (*b*) The fluorescent screen to be fitted with lead glass equivalent to not less than 1 mm. of lead, and to be large enough to cover the area irradiated when the diaphragm is opened to its widest. Practical difficulties militate at present against the recommendation of a greater degree of protection. (*c*) A travelling protective screen, of material equivalent to not less than 2 mm. of lead, should be employed between the operator and the X ray box. (*d*) Protective gloves to be of lead rubber (or the like) equivalent to not less than ½ mm. of lead and to be lined with leather or other suitable material. (As practical difficulties militate at present against the recommendation of a greater degree of protection, all manipulations during screen examination should be reduced to a minimum.) (*e*) A minimum output of radiation should be used, with the bulb as far from the screen as is consistent with the efficiency of the work in hand. Screen work to be as expeditious as possible.

2. *Radiographic examinations ("overhead" equipment).*—(*a*) The X ray bulb to be enclosed as completely as possible with protective material equivalent to not less than 2 mm. of lead. (*b*) The operator to stand behind a protective screen of material equivalent to not less than 2 mm. of lead.

(II.) X Rays for Superficial Therapy.

It is difficult to define the line of demarcation between superficial and deep therapy. For this reason it is recommended that, in the reorganisation of existing, or the equipment of new, X ray departments, small cubicles should not be adopted, but that the precautionary measures suggested for deep therapy should be followed. The definition of superficial therapy is considered to cover sets of apparatus giving a maximum of 100,000 volts (15 cm. spark-gap between points; 5 cm. spark-gap between spheres of diameter 5 cm.).

Cubicle System.

Where the cubicle system is already in existence it is recommended that: (1) The cubicle should be well lighted and ventilated, preferably provided with an exhaust electric fan in an outside wall or ventilation shaft. The controls of the X ray apparatus to be outside the cubicle. (2) The walls of the cubicle to be of material equivalent to not less than 2 mm. of lead. Windows to be of lead glass of equivalent thickness. (3) The X ray bulb to be enclosed as completely as possible with protective material equivalent to not less than 2 mm. of lead.

(III.) X Rays for Deep Therapy.

This section refers to sets of apparatus giving voltages above 100,000. (1) Small cubicles are not recommended. (2) A large, lofty, well ventilated and lighted room to be provided. (3) The X ray bulb to be enclosed as completely as possible with protective material equivalent to not less than 3 mm. of lead. (4) A separate enclosure to be provided for the operator, situated as far as possible from the X ray bulb. All controls to be within this enclosure, the walls and windows of which to be of material equivalent to not less than 3 mm. of lead.

(IV.) X Rays for Industrial and Research Purposes.

The preceding recommendations for voltages above and below 100,000 will probably apply to the majority of conditions under which X rays are used for industrial and research purposes.

(V.) Electrical Precautions in X Ray Departments.

The following recommendations are made: (1) Wooden, cork, or rubber floors should be provided; existing concrete floors should be covered with one of the above materials. (2) Stout metal tubes or rods should, wherever possible, be used instead of wires for conductors. Thickly insulated wire is preferable to bare wire. Slack or looped wires are to be avoided. (3) All metal parts of the apparatus and room to be efficiently earthed. (4) All main and supply switches should be very distinctly indicated. Wherever possible double-pole switches should be used in preference to single-pole. Fuses no heavier than necessary for the purpose in hand should be used. Unemployed leads to the high tension generator should not be permitted.

(VI.) Ventilation of X Ray Departments.

(1) It is strongly recommended that the X ray department should not be below the ground level. (2) The importance of adequate ventilation in both operating and dark rooms is supreme. Artificial ventilation is recommended in most cases. With very high potentials coronal discharges are difficult to avoid and these produce ozone and nitrous fumes, both of which are prejudicial to the operator. Dark rooms should be capable of being readily opened up to sunshine and fresh air when not in use. The walls and ceilings of dark rooms are best painted some more cheerful hue than black.

(VII.) Radium Therapy.

The following protective measures are recommended for the handling of quantities of radium up to one gramme: (1) In order to avoid injury to the fingers the radium, whether in the form of applicators of radium salt or of emanation tubes, should always be manipulated with forceps or similar instruments, and it should be carried from place to place in long-handled boxes lined on all sides with 1 cm. of lead. (2) In order to avoid the penetrating rays of radium all manipulations should be carried out as rapidly as possible, and the operator should not remain in the vicinity of radium for longer than is necessary. The radium when not in use should be stored in an enclosure, the wall thickness of which should be equivalent to not less than 8 cm. of lead. (3) The handling of emanation should, as far as possible, be carried out during its relatively inactive state. In manipulations where emanation is likely to come into direct contact with the fingers thin rubber gloves should be worn. The escape of emanation should be very carefully guarded against, and the room in which it is prepared should be provided with an exhaust electric fan.

Existing Facilities for Ensuring Safety of Operators.

The governing bodies of many institutions where radiological work is carried on may wish to have further guarantees of the general safety of the conditions under which their personnel work. (1) Although the Committee believe that an adequate degree of safety would result if the recommendations now put forward were acted upon, they would point out that this is entirely dependent upon the loyal coöperation of the personnel in following the precautionary measures outlined for the benefit. (2) The Committee would also point out that the National Physical Laboratory, Teddington, is prepared to carry out exact measurements upon X ray protective materials and to arrange for periodic inspection of existing installations on the lines of the present recommendations. (3) Further, in view of the varying susceptibilities of workers to radiation, the Committee recommend that wherever possible periodic tests—e.g., every three months—be made upon the blood of the personnel, so that any changes which occur may be recognised at an early stage. In the present state of our knowledge it is difficult to decide when small variations from the normal blood-count become significant.

The Committee is constituted as follows:—

Chairman: Sir Humphry Rolleston, K.C.B. Members: Sir Archibald Reid, K.B.E., C.M.G., St. Thomas's Hospital; Dr. Robert Knox, King's College Hospital; Dr. G. Harrison Orton, St. Mary's Hospital; Dr. S. Gilbert Scott, London Hospital; Dr. J. C. Mottram, pathologist, Radium Institute; Dr. G. W. C. Kaye, O.B.E., National Physical Laboratory; Mr. Cuthbert Andrews. Hon. Secretaries: Dr. Stanley Melville, St. George's Hospital; Prof. S. Russ, the Middlesex Hospital. Address: care of Royal Society of Medicine, 1, Wimpole-street, W. 1.

THE CAVENDISH LECTURE.

Dr. Christopher Addison delivered the Cavendish Lecture before the West London Medico-Chirurgical Society in the Council Chamber of the Kensington Town Hall, London, on June 17th. Dr. F. J. McCann, who presided, said that it had been given to few men in the course of a single lifetime to rise to eminence in two professions. Dr. Addison after being a distinguished teacher of anatomy had become an important Minister of the Crown, and had filled the posts of President of the Local Government Board, Minister of Munitions, Minister of Reconstruction, and Minister of Health with conspicuous ability.

The Part of the State in the Prevention of Disease.

During the last century, said Dr. Addison, the country had become an industrial, as distinct from an agricultural, nation, and in the past the short-sighted policy had been adopted of practising the doctrine of individual effort and the survival of the fittest in its most unthinking form. Whatever that system might mean to the individual it was not "good business" to run up habitations anyhow, on any spare spot of ground, to bring young children into factory life, to have factories and industries so organised that they were prejudicial to the lives of those engaged in them. Our statute books were crammed with expedients adopted from time to time in the endeavour to prevent the effects of this kind of scramble. Among the legacies bequeathed to us by this condition of things it would be interesting to know what our slums had cost in Poor-law expenditure, in provision of sanatoriums and convalescent homes, in amelioration of physical disabilities, and in industrial inefficiency and unemployment resulting from those disabilities. The sum might even challenge comparison with our war debt. The best available knowledge and professional advice were needed to undo the evils of the past, but there was an opponent to be reckoned with in the shape of a certain type of latter-day economist who would readily spend millions on armaments, but would question every item spent on a system of preventive services.

The Need for Preventive Medicine.

Knowledge was naturally always in advance of its application. The average medical practitioner did what he could in the cause of preventive medicine by advising his patients, but most of his time was spent in attending to the sick and bringing them back to health. There was, however, a serious deficiency in regard to the teaching of preventive medicine in our present scheme of medical education. When an attempt was made to deal with causes which might affect in bulk avoidable disabilities, difficulties arose which were beyond the bound of individual effort, and to deal adequately with these causes public education was needed. Voluntary aid was most useful, as the report of Lord Cave's Committee had shown, in regard to hospitals, but the action of public bodies, with the power of the State behind them was also required. A State medical service was no panacea, and it was certain that large categories of the work to be undertaken in the combat against disease and disablement could only be dealt with by civil or lay authorities. Dr. Addison then described in some detail the various municipal bodies who shared in the administration of health matters, and referred to the waste and muddle that resulted from incoördination of the work of these bodies. In 1919 the public funds expended on direct health service and in payments to those who were sick amounted in England and Wales alone to nearly £46,000,000. At a time of national stringency and when the disastrous records of the war, with its multitude of men classified as unfit, were still fresh in our minds, it behoved all men of patriotic goodwill to examine the mass of sickness indicated by this expenditure, to inquire to what extent it was preventable, and to frame the measure of policy accordingly. We were now at the commencement of a new period of revelation and inquiry, and, though our information was as yet scanty and imperfect, the importance of acquiring it was being clearly appreciated both generally and in industry. An examination of the ailments for which insured persons sought medical advice in 1916 showed that, excluding influenza, tuberculosis, pneumonia, malignant and other defined diseases, nearly 1 in 3 of the people required medical attention because of colds, nasal and bronchial catarrh, and digestive disorders. Here was presented an opportunity for common-sense instruction and for further research of well-nigh incalculable value. The difficulty was to devise ways and means of disseminating reliable information. It was of little use to give advice upon which the majority of the people could not act, and it was necessary to guard against the reactions which followed on advice which proved to be unavailing. There were many voluntary organisations which were exceedingly helpful though difficulties were presented by their multiplicity. Beyond these medical research on sound lines must be encouraged, for it was one of the most economical and rewarding directions of effort open to the community. Over and over again during the war, at the Ministry of Munitions and in the armies, it was found that small expenditure upon research under the superintendence of the Medical Research Committee produced saving which not only repaid the expenditure incurred, but more than paid the whole cost of all the Committee's efforts for a whole year, and in some cases for the whole time of its existence since 1912. There was also need for improvement in the home and in domestic habits and conditions. The medical schools might with great advantage pay more attention to instruction in the beginnings of disease and to the importance of those so-called minor ailments which were among the most disabling in so far as the mass of the community was concerned.

Summary of the Present Situation.

In concluding his lecture Dr. Addison said that well-considered effort was required in at least five directions: the spread of useful information and instruction, steady progress in the provision of better home conditions, encouragement of research and inquiry—not only into the more strictly scientific aspects of medical problems but extending beyond this into the field of employment and industrial conditions—improvement of facilities for early diagnosis and treatment, and a better organisation and direction of agencies charged with responsibility in health matters. At a time of national and world impoverishment we were confronted with a mass of physical disablement, much of which was realised, even with the knowledge now available, to be preventable. Tens of millions a year were poured out in an endeavour to mitigate its ill-effects, while towards the removal of the causes of these effects our efforts by comparison were insignificant and disconnected. There was work here for more than one generation, but recent experience gave good ground for encouragement.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Medical Meetings.

WE are in the midst of a series of meetings of medical societies. The ninety-third annual meeting of the Swiss Medical Federation was held in Basle on May 28th and 29th. Several hundred practitioners were present. The opening paper on the first day, on Methods for the Extraction of Foreign Bodies in the Œsophagus, was read by Prof. Oppikoper of Basle. At a social gathering following, the production of a play entitled "Steinach" by medical amateur actors caused great amusement. The author is a leading Swiss neurologist, and I only mention the play to show that the medical world here has not much use for the Steinach operation and its propaganda. The morning session of the second day of the meeting was devoted to demonstrations in the various clinics and medical institutes of the town. Prof. Doerr of Basle read a paper on "Idiosyncrasies," followed by a discussion in which Profs. Sahli of Berne and Bruno Bloch of Zurich took a prominent part. The latter emphasised the great importance of idiosyncrasies as a cause of eczema, idiosyncrasy being probably the clue for the solution of the eczema problem.—The nineteenth annual conference of the Swiss Neurological Society took place in Fribourg on June 4th and 5th under the presidency of Prof. Robert Bing of Basle. The subject for discussion was Regeneration in the Nervous System. Prof. Bing approached it from the clinical point of view, Dr. Perret of Montreux as a surgeon and Prof. Hedinger of Basle contributed a valuable paper from the pathological and anatomical side.—The Swiss Society of Surgeons is meeting in Aarau on June 25th and 26th. Surgery of the Gall Ducts will be the subject for a general discussion.

Small-pox near Basle.

In Basle and in Oerlikon near Zurich there is at present an outbreak of small-pox. The disease was brought to Basle by a German railway official. So far we have in Basle 10 cases with one death. At Oerlikon there are 97 cases; none of these had ever been vaccinated except one lady aged 65, who had been vaccinated when 5 years old, and one other patient who was vaccinated 30 years ago. These two epidemics should be a warning signal to our country, which has no compulsory vaccination. Compulsion was rejected some 20 years ago by a people's referendum. There is now a great rush to the vaccination stations and a movement is afoot to re-introduce compulsion by an appeal to a better-informed electorate.

Imitations of Salvarsan.

There was never a time when imitations and sophistications of drugs was so frequent. During the war nearly all countries placed embargoes on the import of medicaments, and owing to this the supply became scanty. The drugs rose in price and in consequence became a popular object of smuggling. Switzerland, with its high exchange rate, soon attracted the smugglers. In the back restaurants of Basle morphine, cocaine, and salvarsan were bought, sold, and re-sold. The fact that many persons engaged in the speculative trade of drugs had no knowledge whatever of their pharmacology enabled certain unscrupulous vendors to profit and to sell their customers imitations. The most prominent of the drugs imitated was salvarsan. Dr. Hunziker, director of the health office of Basle, who investigated the question, at a recent meeting of the Basle Medical Society gave a description of some samples of counterfeited salvarsan. A very clumsy substitute was contained in a bottle of green glass, roughly sealed, bearing the inscription: "Original package for Oversea Trade. Neo-Salvarsan 0·3. Contents 500 g." Chemical analysis showed that the yellow powder consisted of sulphate of barium and chromate of lead. A bricklayer of Basle had brought this bottle from a German plasterer for 6000 marks (400 francs) The contents of a similar bottle were found to consist of dust of silicates and rye flour. Three bottles, each containing 500 g. of a yellowish powder, had a label similar to those on the small original packages. The inscription, "500 g. Neo-Salvarsan and 0·4 g. Salvarsan" was sufficient to rouse suspicion. The contents were sulphate of barium, chromate of lead, and a yellow aniline dye-stuff, probably naphthol yellow S. In the trade of these bottles were engaged a hairdresser, a beer retail merchant, and a baker. But the most dangerous imitations of all were those resembling the small, much used salvarsan packages. A parcel with several hundred samples was found by the Basle police at a short distance from the German frontier. The labels closely resembled the original ones, but showed several slips; the name Höchst a. M. was spelled Höchs, in the English text the word "prohibited" ran "prohibitet," and the name of the firm Brüning was wrongly spelt. The contents, a yellow powder, looked very much like the original salvarsan, but consisted only of dust and of salt stained with yellow ochre. The dangers to the public health of this illegitimate trade are obvious, but quite apart from the spurious products the rough handling of the authentic salvarsan by the smugglers is apt to produce oxidisation, when the arsenic components may become more toxic.

BRITISH PHARMACEUTICAL CONFERENCE.

THE 58th annual general meeting was held in Scarborough last week. The President, Major E. Saville Peck, gave an address upon British Pharmacy and its Possibilities. He drew attention to the addresses delivered in recent years on the need for the representation of pharmacists upon the Pharmacopœia Revision Committee, on the institution of an Army Pharmaceutical Corps, on the advisability of the separation of prescribing and dispensing of medicines and the necessity for pharmaceutical research. The President outlined the present unsatisfactory position of the practice of pharmacy, and urged members to work for the establishment of a distinct profession of pharmacy on the lines of that which obtains upon the continent and is suggested in the United States of America. He advocated a wider preliminary education for all those entering the calling, and pointed out the advantage to be gained by insisting that apprentices or students of the Pharmaceutical Society should pass one of the School Leaving Certificate Examinations before registration. Major Peck also advocated the establishment of a university degree in science with pharmaceutics as one of the final subjects, and strongly urged the institution of a Fellowship Examination to include biochemistry and bacteriology with clinical microscopy. Such an examination, and the training required therefor, would enable students to carry out clinical analyses and so assist in diagnosis of disease. It would train men for the work of clinical assistants to medical men in the primary and secondary health centres contemplated by the Ministry of Health. Such men are also required by wholesale houses for the purposes of preparing vaccines and for research upon new drugs and remedies. He urged that the professional spirit should be reawakened in the rank and file of pharmacists and that the local associations should be stimulated to discuss pharmaceutical professional matters. These associations should send delegates to an annual conference so that the considered opinion of members might be focussed and handed on to the council of the society. He advocated the formation of an association of teachers from the various schools of pharmacy recently instituted, the associates to meet annually to discuss subjects in furtherance of pharmaceutical education. He looked forward to the time when a central unifying body should be formed to coördinate and combine all these forces—education, qualification, professional conduct, and research. This would work for the evolution of a profession of pharmacy, which coexistent and interdependent with that of medicine, would assist in the combating of disease and in the improvement of the health of the nation.

Correspondence.

PERMANGANATE OF POTASH AS A STYPTIC FOR SEROUS SURFACES.

To the Editor of THE LANCET.

SIR,—Every surgeon knows the difficulties happening during the separation of adhesions between the intestines and other organs in the abdomen, particularly the often serious hæmorrhage from the separated surfaces. To arrest this various measures have been applied, such as pressure by means of tents or tampons, thermo-cauterisation, or suture. All of these demand much time and are not without danger in themselves. In cases of hæmorrhages from superficial wounds of the serosa after separation of adhesions, I have, since 1901, used kalium hypermanganicum cryst. with the best and quickest results. I lay hold of one or more crystals of the salt with a pair of dissection forceps and apply them to the bleeding points. On contact with this substance the blood coagulates, a clot forms, and in place of the hæmorrhage there is to be found a black, dry, aseptic scab. The bleeding stops immediately. After some seconds the scabs are cautiously removed with fine blunt forceps, and on the wounded surface of the serosa there remain only smooth black spots.

The moment that permanganate of potash touches the blood, oxygen is set free in a nascent state and an exceedingly powerful aseptic effect results. If the bleeding surface is large, a pinch of permanganate crystals is folded in a piece of lint and applied continuously to the wound for a few seconds. I have employed this styptic method for nearly 20 years without any complications.

I am, Sir, yours faithfully,
JOHN DSIRNE, M.D.,
Late Chief of the Surgical and Urological Clinics of the University of Moscow.
Constantinople, May 24th, 1921.

X RAY LESIONS AND MEDICINAL WATERS:

A SUGGESTION.

To the Editor of THE LANCET.

SIR,—The losses, amongst radiologists, which we all deplore, may well lead us to ask whether we have sufficiently recognised the resources of treatment. An expectant attitude has sometimes prevailed amongst medical men in the treatment of chronic affections and those of which the origin is still obscure. But there are in nature powerful remedial forces which have often given good results in just those chronic and toxic maladies in which other means have failed. We refer to air, climate, medicinal waters. The retarding as well as the exciting action of some of these forces in the evolution of disease—catarrh, rheumatism, syphilis and tuberculosis—is well known. With regard to cancer, there is evidence that the ingestion of certain bicarbonated waters stimulates the development of malignant growths of the stomach and liver, and accelerates the fatal issue. As the bicarbonate of sodium in ordinary doses produces no such effects, we are led to conclude that these waters, in which, as we know, the salts are *ionised*, have properties different from those of the pharmaceutical preparations. Are there not then, perhaps, waters that, combined with climatic treatment, may delay or even prevent the cancerous process? Within the last 20 years the science of medical hydrology has advanced by experimental methods, and something more than clinical experience entitles us to consider such an hypothesis. We propose to compare certain effects of X rays and radium with those of medicinal (and especially arsenical) waters. And we suggest that there are sufficient grounds to make it advisable that those radiologists who are liable to blood and tissue changes as a result of exposure to X rays should submit themselves to courses of climatic and hydrological treatment.

1. *Blood and Tissue Changes after Exposure to X Rays.*—Heinecke first noticed after the exposure of an animal to X rays a diminution of the circulating lymphocytes and a selective destruction of lymphogenic tissues. A maximum loss of red and white cells has been noticed about 48 hours after exposure, and five to six weeks may be required for the re-establishment of the blood.[1] Cases have been recorded in which after a single treatment for cancer the alteration of the blood was such that it became irreparable, the patient dying cachectic, in spite of the cure of the local lesion. Certain observers have stated[2] that the "resistance to cancer and tuberculosis in animals is attended by an increase in number of the circulating lymphocytes, and that the resistance as well as the lymphocytosis may be destroyed by X rays in proper dosage."

The action of radium and X rays upon the tissues is described as: in minimum doses stimulative, and in larger doses destructive and toxic, the nucleus of cells being especially affected.[3] There is reason to think that a definite and continuous dosage may be capable of producing a "habit of growth" in sensitive tissues. It has been shown that whilst radium may bring about the destruction of cells in lymphosarcoma, with toxic symptoms and rise of temperature, the same agency, in a different dosage, may stimulate the growth of malignant tumours. The effect of radium and X rays upon the skin is: erythema, brownish discoloration, branny desquamation, with pain and dryness; later, a deeper red coloration, slight blistering, and the swelling and ulceration which constitute radio-dermatitis. The skin is ultimately replaced by scar tissue, without glands or hairs, and with characteristic pigmentation. The chronic stage shows keratinisation with papular growth, forming and shedding scales, and going on towards epithelioma.

2. *Effects of Arsenic and Arsenical Waters.*—Arsenic and sulphur are two elements existing in the colloidal state in natural medicinal waters, and visible under the ultra-microscope as particles in rapid motion. Both have specific actions upon the skin and upon deeper tissues. We are now concerned with arsenic. When it is taken internally, the following changes in the skin have been observed: a short phase of epithelial proliferation; followed by hyper-keratinisation; an atrophic phase, affecting principally the interpapillary processes, the skin becoming planiform with partial destruction and detachment of the epidermal cells. In chronic arsenical poisoning a variety of exanthemata are observed. In small repeated doses arsenic is believed to cause increase of assimilation and to stimulate the formation of hæmoglobin or red cells. In massive doses, arsenic resembles X rays in causing destruction of the cells of the liver, kidneys, capillaries, and blood. Cases of aplastic anæmia following the administration of salvarsan have been recorded.[4] Certain pathological tissues (malignant lymphoma, syphilis) appear to be especially susceptible to the dissimilative action of arsenic.

The European arsenical waters are represented by La Bourboule and Levico. Clinical experience has for many years proved the value of waters of this class in anæmia, "lymphatic affections" and chronic dermatoses. The La Bourboule water, of which one litre is chemically equivalent to 21 drops of Fowler's solution, forms what may be called an isotonic arsenical serum. Certain doses were injected into the veins of animals after extreme venesection, and the process of recovery watched.[5] These and further experiments by one of us have shown the superiority of this water to artificial serums, both from the point of view of the restoration of the red and white cells and of the hæmoglobin.[6]

Some recent writers[7] hold that in cancer the normal lipoid equilibrium of the tissue cells is disturbed, causing a change in the permeability of the cellular envelope, and that this disturbance of the lipoid equilibrium is increased by bicarbonated waters. Dr. Jacques Loeb has shown that the fertilising action of spermatozoa can be reproduced in all its details by exposing the ovum for one minute in sea water, to which has been added a certain quantity of monobasic fatty acid, and thereafter for about half an hour in sea water, of a certain determined saline proportion. In this process soaps are formed and break down the lipoid equilibrium of the cell. The negative electrolytic ions of the mineral water pass through the cell membrane and precipitate the colloidal substance. Loeb has emphasised the essential part played by electrolytes in many of the phenomena of life. What could, on a priori grounds, be more capable of modifying the equilibrium of the cell and the permeability of the cell wall than natural waters with their complex and varied electrolytic elements? The observation of colloid disturbance, and also of anti-anaphylaxis, provoked by the injection of the Bourboule water, appears to show a marked action of these waters on cellular permeability. When we reflect that the majority of chronic diseases are in their nature toxæmic, with anaphylactic phases, is it not reasonable to hope to find elements amongst natural waters which have a selective action upon particular cells and in particular toxæmias? Arsenic is *par excellence* a selective remedy.

3. *Interaction of Remedies.*—An association and interaction of remedies appear to be necessary for the process of recovery. According to this principle, exemplified in hydrological medicine, waters, in natural alliance with climate, modify various predispositions to premature degeneration and functional failure. But it is necessary to select the climatic and other influences, so that they will contribute to hydrological treatment—that is, will augment and not lessen its effect. In the case of the X rays worker a moderate degree of altitude and the action of cold and of the sun (frigotherapy, hydrotherapy, heliotherapy), as on the mountain slopes of Auvergne or Tyrol, or in the north-east of Scotland, should definitely assist the action of waters. One of us has observed during many summers in the district last mentioned the prevention and retardation of degenerative processes and recovery from anæmia and toxic conditions, especially among brain workers, who made a habit of spending a certain number of weeks annually in the north country. The recovery of strength and colour resulted sometimes from the northern climate alone, but more often from climate associated with waters. Dr. Robert Knox, and in France Dr. Bélot, insist upon the necessity of prolonged change of air for radiologists. The latter has made a habit, since the introduction of X rays, of absenting himself for three months in each year, and has had as yet no lesions of the skin, and the blood has remained normal. (Many operators, as we know, have lesions of the hand with a normal blood.) We venture to go one step further, and to suggest that in combined climatic and hydrological treatment, carried on from year to year, may be found an effective means of preventing and retarding the serious changes, both in the blood and tissues, to which some of our colleagues are liable.

We desire to express our acknowledgments to Prof. W. S. Lazarus-Barlow and to Dr. Stanley Melville for valuable data.

We are, Sir, yours faithfully,
R. Fortescue Fox.
Paul Ferreyrolles.

THE DIAGNOSIS OF DYSENTERY BY THE SIGMOIDOSCOPE.

To the Editor of The Lancet.

Sir,—Dr. P. Manson-Bahr and Dr. A. L. Gregg in your issue of May 28th and Dr. A. F. Hurst on June 4th deal with the sigmoidoscopic diagnosis of dysentery. Fifteen years ago I pointed out the importance of a sigmoidoscopic examination in all cases of ulcerative colitis, and since the war this has become the recognised means of diagnosis in chronic dysentery. Without such an examination it is impossible to be certain what kind of ulceration is present, what stage it has reached, or how extensive the area involved. No doctor would be willing to treat an ulcerated throat without first looking at it, and yet one frequently sees cases of ulcerative colitis that have been under treatment for months without an examination of the inside of the bowel having been made.

I agree with Dr. Hurst that it is easy to distinguish between the ulceration of amœbic dysentery and that of bacillary dysentery, although their symptomatology may be similar. Several other types of ulceration of the colon can be distinguished. When cases of chronic dysentery are systematically examined with the sigmoidoscope it is found that both amœbic and bacillary dysentery are frequently followed by an ulcerative colitis of a different type from the original infection and due no doubt to secondary infection, usually with a streptococcus. This secondary infection is much more chronic than the original disease, and has often little tendency to get well. It is the cause of many of the cases of chronic dysentery sent back to this country from the East, and is similar, if not identical, to the form of ulcerative colitis which is indigenous as a primary condition in this country. It does not react to emetin injections or to antidysenteric serums.

It is important that when this secondary type of ulceration has developed it should be recognised, and this can only be done by sigmoidoscopic examination. I believe it to be essential that all cases of dysentery which do not clear up in reasonable time under proper treatment should be examined to see what type of ulceration is present in the colon. These severe secondary ulcerations of the colon clear up very satisfactorily after an appendicostomy, and it is our experience at St. Mark's Hospital, where we have to treat a considerable number of such cases, that when an appendicostomy is performed in time complete recovery is the rule. Too often, however, a surgeon is only called in as a last resort, and when the patient has little or no recuperative power left. When treated at a stage before the general health is seriously damaged the rapidity of recovery is often astonishing.

I feel sure that when a systematic examination of the colon with the sigmoidoscope in all cases of dysentery and ulcerative colitis becomes the rule, we shall have far fewer deaths from these conditions than is the case at present. As Dr. Hurst points out in his letter, the sigmoidoscope is also the only satisfactory check to treatment in these cases, and no case can be considered cured until an examination shows that the mucosa is normal.

I am, Sir, yours faithfully,
J. P. Lockhart-Mummery, F.R.C.S.

Hyde Park-place, W., June 17th, 1921.

CONTROL OF VENEREAL DISEASE: THE RED CROSS REGIONAL CONFERENCE.

To the Editor of The Lancet.

Sir,—Your report of this Conference, appearing in your issue of June 18th, quotes the Secretary of the National Council for Combating Venereal Diseases as saying: "A noteworthy point is the fact that the question of self-disinfection, which has appeared such an important and vexed factor in the campaign in England, provoked very little interest at this Conference of experts." The reason is not far to seek, and was due to the fact that the National Council for Combating Venereal Diseases (who had been adopted by the League of Red Cross Societies in Geneva as the recognised channel in this country for communication on these subjects) had selected as delegates Colonel L. W. Harrison, Dr. F. N. Kay Menzies, and Mrs. C. Neville Rolfe (Mrs. Gotto), who are well-known opponents to the immediate self-disinfection policy.

The Society for the Prevention of Venereal Disease, in reply to a request that they might be represented at the Conference, received a most courteous reply from the Secretary of the Danish Red Cross, intimating that he would be pleased to welcome delegates from our Society, but that the selection of delegates was entirely in the hands of the British Red Cross. Upon my communicating with the British Red Cross, I was told that the Society for the Prevention of Venereal Disease could not be represented, as the above-mentioned delegates had already been selected. The views of that very large section of the people in this country, who support the policy of immediate self-disinfection advocated by the Society for the Prevention of Venereal Disease, had therefore no opportunity of being presented to the Conference, and this important aspect of venereal disease prevention was largely neglected, mainly through the action of the National Council for Combating Venereal Diseases.

I am, Sir, yours faithfully,
H. WANSEY BAYLY,
Harley-street, W., June 17th, 1921. Hon. Sec., S.P.V.D.

THE PROPERTIES AND COMPOSITION OF ETHANESAL.

To the Editor of THE LANCET.

SIR,—I have administered the new general anæsthetic, described under the name ethanesal in your issue of June 4th by Dr. R. L. M. Wallis and Dr. C. L. Hewer, to 32 patients (15 male and 17 female). In three cases a little ether was used in the induction stage. In all but two the apparatus used was the warm ether "bomb." By this short trial a favourable impression has been formed; the narcosis has been at least as good as with ether, and the after-effects unusually trifling, except that one woman developed on the next morning a mild bronchitis which lasted for several days; she had, however, caught cold just before the day of operation. 28 oz. used in the bomb for maintenance only lasted for 307 minutes, or 5·47 oz. per hour, as compared with 4·7 oz. per hour of ether under similar conditions.

Several factors probably combine to make the difference greater than should be—chiefly the general length of the operations, which were, perhaps, twice as long in the ether cases. It would be of interest to know from the manufacturers precisely what quantity of ketones, and how much CO_2 and ethylene, are added to the ether in this new anæsthetic.

I am, Sir, yours faithfully,
K. B. PINSON,
Anæsthetist, Manchester Royal Infirmary.
June 19th, 1921.

DIGITALIS AND THE PERIPHERAL CIRCULATION.

To the Editor of THE LANCET.

SIR,—I readily admit that I have not grasped the "principles" upon which Dr. I. Harris in his paper of your issue of May 21st bases his conclusions on the pharmacology of digitalis. First, it is impossible to agree with the primary assumption that a large systolic output will necessarily give rise to a correspondingly large pulse pressure and vice versâ. In the presence of an increased systolic output the degree of pulse pressure will depend wholly upon the degree of vaso-dilatation or constriction present. Pulse pressure may even be lessened in the presence of increased systolic output. Again, it is impossible to agree that, if under the influence of digitalis the pressure in the veins is not increased, these will be able to pass a greater amount of blood per time-unit into the heart at the increased pressure necessary to cause the rise of intra-cardiac pressure depicted by Dr. Harris. Finally, simple considerations of physics prevent agreement with the statement that a force acting *a tergo* can propel in a given time-unit through a system of elastic tubes, such as the arterial, a greater volume of fluid in the absence both of increased intratubal pressure or tubal dilatation. In view of the fact that his "principles" are based on such errors and disregard of elementary physical laws Dr. Harris need feel no surprise if one is unable to grasp them.

I am, Sir, yours faithfully,
Eltham, June 20th, 1921. W. J. GRANT.

THE FEDERATION OF MEDICAL AND ALLIED SOCIETIES.

To the Editor of THE LANCET.

SIR,—A memorandum issued by the Council of the British Medical Association on Jan. 29th, 1921, and reprinted in its Annual Report of April 30th, contradicts statements in Dr. R. Fothergill's letter published in your last issue, and at the same time answers his questions. Dealing with the qualifications of a body to represent the profession as a whole, that memorandum states: "The body must not profess to promote the interests of the community rather than those of doctors"; "Bodies exclusively or mainly scientific have no concern with medical politics"; "They must be trained in expressing opinions on such matters" and, speaking of the Association, that "Its members are trained, both locally and centrally in dealing with medical politics."

I am, Sir, yours faithfully,
N. HOWARD MUMMERY.
Vere-street, W., June 17th, 1921.

THE TREATMENT OF DIABETES.

To the Editor of THE LANCET.

SIR,—In your issue of June 18th Dr. Ph. Horowitz has disagreed with a statement which I made in the review of his book. I stated that sodium nitro-prusside test was a better test for aceto-acetic acid than for acetone. I based that statement on the work of Dr. W. H. Hurtley (THE LANCET, 1913, i., 1160). Aceto-acetic acid can be detected in a dilution of 1 in 400,000, whereas acetone can only be detected in a dilution of 1 in 20,000. With the ferric chloride test, aceto-acetic acid can be detected in a dilution of 1 in 100,000 if it is dissolved in water, but in urine the test is much less sensitive because the pigments of the urine interfere with the reaction. It follows, therefore, that the nitro-prusside test for aceto-acetic acid will often be positive when the ferric chloride test is negative. It has also been shown by Folin and Emden independently that acetone is present in very small amounts in diabetic urine when it has been freshly passed. When the urine has stood for a little time, the acetone increases in amount owing to the decomposition of the aceto-acetic acid into acetone. Hence, if the nitro-prusside test is positive in fresh urine, it means that aceto-acetic acid is present in the urine.

I am, Sir, yours faithfully,
June 17th, 1921. THE WRITER OF THE REVIEW.

EARLY DIAGNOSIS IN DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—May I add a few words to the discussion on this subject. I should like to emphasise the great value of antitoxin in non-diphtheritic tonsillitis. Fifteen to twenty years ago I saw a large number of severe septic throats. I always gave antitoxin before swabbing, and found that it was just as useful in those throats that were streptococcic, as in the diphtheritic, and the results just as rapid and striking. Indeed, after a short experience, I was able to assure the boy that within 12 hours he would feel well, and this was almost invariably the case; the actual physical signs took rather longer to clear up, about 24 hours. I never tried normal horse serum, and so cannot be sure as to the exact curative agent. Of the cures themselves I had and have no doubt; of recent years I have no experience, as (owing to a new drainage system) I have no sore throats.

I am, Sir, yours faithfully,
MEDICAL OFFICER TO A BIG PUBLIC SCHOOL.
June 19th, 1921.

Public Health Services.

THE OXFORD CONTRIBUTORY HOSPITAL SCHEME.

THE final report of the Voluntary Hospitals Committee commends the system of weekly contributions, carried further than elsewhere by the Radcliffe Infirmary and County Hospital at Oxford, as an admirable instance both of the benefits of a system of collections from wage earners and of the advantages of hospital coördination. The Radcliffe, which is the only large hospital in the northern part of Oxfordshire and is connected with the medical school of the University, appears to perform the functions both of a "secondary health centre" and of a "teaching hospital" as defined in the Dawson report. It takes all the active cases from the Poor-law infirmaries in its district, and has succeeded in linking up with its work the primary and cottage hospitals as well as, to some extent, the district nursing service within its radius. The hospital has recently organised with conspicuous success a scheme for obtaining weekly contributions, not only from workmen, but from the whole wage-earning population of the towns and villages in its area. The conditions of this scheme are stated as follows:—

1. A contributor of 2*d.* a week is entitled to free treatment.
2. In the case of married people, when the husband and wife each subscribe 2*d.* a week, their children are also entitled to free treatment up to wage-earning age, and from then until they are earning adult's wage, each child pays 1*d.* a week. The children of a widow or widower are also entitled to free treatment up to wage-earning age on the 2*d.* contributions of their parent.
3. Non-contributors will in future be expected to contribute towards their maintenance in the hospital, but no payment is required from old-age pensioners.
4. Every case must be accepted by a doctor or surgeon as suitable for hospital treatment.
5. No supporter will in future require a "turn."

Although the scheme was only established in September last, there are already 35,000 contributors from 288 firms and 165 village aid associations. The aid committees are represented on the board of governors and it is proposed that they shall appoint one-third of the management committee. The scheme is expected to yield something like £25,000 of "new" money.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

City of Carlisle.

Dr. J. Beard's annual health report for the year 1920 is a very complete one. As in other towns a marked increase took place in the number of births, and for 1920 the birth-rate was 24·7, the highest recorded since 1906. The death-rate was 12·5, and the infant mortality rate 80, the same as that recorded for England and Wales. "About 130 privies still exist in the outlying parts of the city, which were added in 1912, most of which will be replaced by water-closets when the proposed extensions to the sewers are completed." There are no cesspools or ashpits in the city; portable receptacles for house refuse have been in use for the last 20 years. Most of the refuse is tipped into old claypits or on low-lying land near the river. "The tips are covered with soil, and no nuisance arises from this method of disposal." A small destructor deals with offal from the slaughter-house and refuse which might cause a nuisance. An unusual arrangement is in operation by which all cows purchased by city cowkeepers are purchased subject to examination by the veterinary inspector, and any found to be unsatisfactory are returned to the sellers. Of 221 new cows purchased under this system in 1920, 10 were found by the veterinary inspector to be unsound and were returned to the sellers. Eight samples of milk were examined for tubercle bacilli with a negative result. During May and June there was a return of the influenza, 20 deaths being registered from this cause and 13 from acute influenzal pneumonia during the period mentioned. (Several towns, e.g., Sheffield, Blackburn, Halifax, and Sunderland, had similar attacks somewhat earlier in the year.) Otherwise the prevalence of ordinary infectious diseases was low, there being two deaths from diphtheria, one from enteric fever, and four from measles in an estimated population of 57,697. In Carlisle, as in other towns, there was an increased mortality from pulmonary tuberculosis during the war. A decline in this mortality began in 1918, and in 1920 the deaths were 36, making a rate of 0·63 per 1000 of the population, the lowest ever recorded in the city. The corporation have no residential institution of their own, but reserve 20 beds in the Blencathra Sanatorium for early and intermediate cases of pulmonary tuberculosis. There is no provision for advanced cases. During the year Coledale Hall was purchased for the purpose, but, owing to opposition inspired by unreasonable fear of the spread of infection to the neighbourhood, the project was given up, and the hall handed over to the education committee for an open-air school. The school nurses also act as tuberculosis nurses—a very satisfactory arrangement. Encouraging results have been obtained from the treatment by tuberculin of specially selected cases, mostly children.

A treatment centre for venereal diseases has been established jointly by the corporation and the county council at the Cumberland Infirmary, and during the year 112 male and 51 female patients were treated for these diseases. Midwives attended 821 out of the 1425 births—about 57 per cent.—and sent for medical help in 92 cases. In 65 cases a notification was received of the intention to substitute artificial for breast-feeding. Dr. Beard gives a list of the reasons put forward to justify artificial feeding, and comments as follows:—

> "An examination of the above figures suggests that in a number of instances the midwife should have refused to countenance the substitution of artificial feeding of the infants. This would have avoided the many risks connected with artificial feeding, and secured the only food natural to infants, which is cheaper, cleaner, safer, and more easily digested. It is difficult to believe that any mother would withhold her milk from her infant on purely personal grounds if the advantages of breast-feeding and the risk attending artificial feeding were put sufficiently strongly before her by a midwife during the time she is in attendance. It should also be remembered by the midwife that in this connexion her duty to the mother commences at the time she is engaged to attend upon her, and not merely with the commencement of labour."

Thirty-six cases were admitted to the Corporation Maternity Hospital (opened in May, 1920) during the year. No cases occurred of maternal death, puerperal sepsis, or ophthalmia neonatorum. Three mothers were unable to breast-feed owing to albuminuria with general anasarca, cardiac disease, and profound anæmia respectively. An antenatal clinic is held at the hospital (attended by 46 expectant mothers since its opening), and also an infant consultation clinic. There are four voluntary infant welfare centres and a day nursery, with an average attendance of about 12, all linked up with the corporation scheme, by the corporation maternity and child welfare medical officer acting as medical supervisor. Dr. Beard thinks the infant mortality could be still further reduced were it not for unnecessary artificial feeding, and points out that the debility caused by artificial feeding continues long after infancy, as "proved by the fact that 50 per cent. of the children dying between the age of 1 and 5 years were artificially fed." Complete information is given as to the result of all the 56 notified cases of *ophthalmia neonatorum*. Both eyes were affected in 43 cases, one eye in 13, and all the cases resulted in recovery except two, in which the sight of one eye will be slightly impaired owing to damage to the cornea. There were 11 deaths from whooping-cough, which Dr. Beard points out is regarded by parents as a minor ailment, and says:

"I am not sanguine enough to hope for much alteration in the apathy and callousness of certain parents unless and until whooping-cough is made compulsorily notifiable."

Carlisle, like other towns, is suffering from overcrowding. We learn from the report that, owing to the lack of building enterprise, only 218 houses have been erected since 1906. No action can be taken with regard to overcrowding, "as it is impossible, until new houses are built, to displace families from their present dwellings." For the same reason "difficulty has been experienced in remedying more serious defects found in houses," and action with regard to the Crown-street and Caldewgate unhealthy areas will have to be delayed. Lowther House, one of the two common lodging-houses, is now owned by the corporation, and the second has been closed as from Dec. 31st as being "totally unfit." The chief sanitary inspector is of opinion that there is unnecessary smoke from factory chimneys, but no action has been taken beyond warnings. It is now well recognised that black smoke from chimneys serving boiler furnaces is unnecessary, and it is to be hoped that the national experience of purer air, as the result of the unfortunate coal dispute, may lead ultimately to a crusade in the matter. The inspector also reports a reluctance on the part of the managers of some milk shops to provide covers for milk storage vessels, and that the present method of disposing of the slaughter-house refuse at the tips is very wasteful.

County Borough of Eastbourne.

The annual health report for 1920 submitted by Dr. W. G. Willoughby is very satisfactory. The temporary rise in death-rates which occurred during the war has subsided. The death-rate was 10·5 per 1000 of the Registrar-General's estimate of the population. The infant mortality rate was 59·8 per 1000 births, 20 less than the rate for England and Wales. The death-rate from pulmonary tuberculosis, 0·56 per 1000, was the lowest ever recorded, and the death-rate from infectious diseases was very low. Other signs of progress are the opening of an open-air school in June, and of a maternity and infant hospital in March. Fifty-eight of the new municipal houses have been opened during the year, but Eastbourne, like other towns, is suffering from overcrowding. This is not surprising when we consider that the population of Eastbourne increased from 34,960 in 1891 to 52,542 in 1911; that the inhabited houses in the same period increased from 5190 to 8967, and that during the war there was a cessation of house-building. The yearly average of houses built during the five years before the war was 103, and during the preceding quinquennium was 132; 138 hut tenements are temporarily occupied, and it is estimated that 150 houses are definitely required over and above the present scheme of municipal building. There are about two males to three females in the population of Eastbourne, and 50 per cent. of the working female population are domestic servants. During 1920 the death-rate among the males was 10·75 per 1000, and among the females 7·20. With a population of this constitution one can hardly attribute the change in the infant mortality rate to anything but increased knowledge and more intelligent care. Thus during the three closing years of last century the infant mortality rates were 139, 145, and 121 respectively, while during the last three years the infant mortality rates have been 74, 57, and 59·8. This is a wonderful record. From the table on p. 39 of the report we note that vaccination in Eastbourne has been almost given up. During 1920 the vaccination officer received 709 certificates of conscientious objection. The births in the vaccination district during 1919 were 750. During the last decade the yearly average of births has been 871, and the yearly average of successful vaccinations 165. During the year 52 cases of venereal diseases were treated at the clinic (opened in September, 1919). Eastbourne has its own tuberculosis hospital of 24 beds, but, in addition to this, 88 patients were sent away to various sanatoriums and hospitals. One of the needs is a hospital for non-pulmonary tuberculosis. Dr. Willoughby mentions that tentative proposals have been made for a joint Sussex arrangement, but have so far come to nothing. The results achieved at Alton have been so good that one cannot help being surprised at the slow progress of this movement for converting cripples into useful citizens.

We congratulate Eastbourne on having a very complete maternity and child welfare scheme, including, as it does, a well-attended antenatal clinic, a hostel for unmarried mothers, a maternity home, an infants' home, and a municipal home-help. There is also a dental clinic for the mothers, and arrangements have been made during the year for boarding out illegitimate infants, some of them at their own homes. The council subsidise a creche, which accommodates 16 children, and one wonders why it is necessary to have a creche in Eastbourne, and whether, with a population of a constitution such as that of Eastbourne, it would not be a sounder policy and more economical to "board out" the babies at their own homes, as has been done for some of the illegitimate babies. The proportion of births attended by midwives is only 27·4 per cent., a very different state of things to that obtaining in industrial towns. Eleven cases of ophthalmia neonatorium were notified during the year without any resulting blindness, though it is not mentioned if any damage to the eyes occurred. The report concludes with a housing survey, to which some reference has already been made.

SCHOOL MEDICAL SERVICE.

Hull.

The service here comprises, besides the school medical officer, two whole-time assistants and five part-time officers, along with two part-time ophthalmic and orthopædic surgeons and a school dentist. The department works in coöperation with the public health, the tuberculosis, and the infant welfare departments. During 1920, 17,799 children underwent routine medical inspection, and 1472 were re-examined. The school dentist found among 4411 children between 6 and 7 years of age, 2550 requiring treatment. In 1917 only 9·2 per cent. of the children had sound teeth, as against 20·5 per cent. in 1920. The number with clean mouths has been increasing steadily each year. It is difficult to believe that any public benefit can result from the high price of milk, yet we are told, "The rapid rise in price and greatly diminished consumption of milk may have called into play more profuse salivation than hitherto, and food instead of being washed down with a drink is formed into a more natural and digestible bolus."

An interesting investigation into the visual and auditory capacity of 4695 children between 6 and 7 years of age was made; 950 having vision of less than 6/12 in both eyes were submitted to a test of refraction, and in the case of 250 glasses were found to be necessary. Unfortunately, the scheme for a large open-air camp school and a residential open-air school has had to be abandoned on account of the expense involved, and so far there are no schools with open-air class-rooms, though the teachers are encouraged to develop playground classes. The organiser of physical training reports a steady improvement in the results obtained from physical exercises, which is noticeable in the carriage and the movement of the children, and we are told that the introduction of the new syllabus into the schools has been responsible for a large amount of this improvement.

Bootle.

There have been certain changes in the administrative staff during the past year, Dr. F. T. H. Wood succeeding Dr. W. H. Daley as school medical officer and medical officer of health, and Dr. Kate M. Cowe succeeding Dr. J. M. Taylor as assistant school medical inspector. Dr. Cowe gives part of her time *to maternity* and child welfare work, thus coördinating these two branches.

There was an average attendance of 11,424 children out of 12,928 on roll, and 39,073 routine and 12,002 special inspections, while 35,863 re-examinations were made. *The number found* at routine inspections without any physical defect totals 27·4 per cent., as compared with 27·3 per cent. last year, 19·9 per cent. in 1918, and 16·5 per cent. in 1917. The more important percentages of physical defects this year are malnutrition, 6·6 per cent; *defective vision*, 13·1 per cent.; enlarged tonsils, 7·5 per cent.; lung disease, 8·7 per cent. These figures correspond closely to those of last year. The number of children referred for further observation or treatment was 62·5 per cent., as compared with 57·6 per cent. in 1919, both high percentages. The scheme for establishing an *open-air residential school* has unfortunately been deferred, and as there is no *provision for open-air education* in Bootle, Dr. Wood suggests the establishment of playground classes wherever possible. Comment is made on the wide variations in the methods employed in the physical training of the children, and it is suggested that the appointment of *an organiser* of *this* department would do much to systematise and coördinate the instruction. Bootle has *three* evening play centres, which are a great attraction, and which have been well attended throughout the year. These centres have done much to promote the social and physical welfare of the children. Examination of children *attending* secondary schools revealed such children to be better in physique. nutrition, and *cleanliness than* the ordinary *average* elementary school child. Of 69 children of school age who *died during the* year, 18 *died from tuberculosis*, 11 from diphtheria, 7 from pneumonia, 5 from heart disease and rheumatic fever, 5 from accidents, 4 from scarlet fever, and 3 from measles. The incidence of tuberculosis here revealed is very striking

Leamington.

The average school attendance here is 1927; 879 routine and 802 special inspections were carried out. The number of children re-examined was 381. No child suffered from malnutrition, and only three cases of definite pulmonary disease were found. *Out of 5787 children inspected by* the nurse, 791 were found to be unclean. The anthropometrical work done by Dr. W. L. Goldie is interesting: In estimating the cephalic index he found on examining 200 boys and 218 girls that 10 boys and 16 girls were dolichocephalic, or had cephalic indices below 75; 127 boys and 151 girls were *mesaticephalic, or had cephalic* indices from 75 to 80; and 63 boys and 51 girls were brachycephalic, where the cephalic index was above 80. *He has* also made investigation into the colour of the eyes and the comparative lengths of the index and ring fingers, and found among other things that an index finger longer than the ring finger is nearly twice as *common amongst* boys as amongst girls.

RONTGEN SOCIETY.—The annual general meeting was held on Thursday, June 16th, *at the rooms of the* Royal Photographic Society, 35, Russell-square, London, W.C. The following officers and *members of council* were elected for the ensuing year. President: Prof. J. W. Nicholson, F.R.S. *Vice-Presidents: Dr.* G. H. Rodman, Sir Ernest Rutherford, F.R.S., and Sir William Bragg, F.R.S. Hon. *Treasurer:* Mr. Geoffrey Pearce. Hon. Secretaries: Mr. E. A. Owen, D.Sc., and Dr. J. Russell *Reynolds. Hon. Editor:* Major G. W. C. Kaye, D.Sc., and 12 members of council. A discussion on "The Physics *of the X Ray Tube*" was opened by Major Kaye. An Exhibition of Modern X *ray Tubes, and a demonstration of the* New Portable Coolidge Outfit—British Thomson-Houston Co., Ltd.—was given. The attention of *members is* called to the exhibition of Radiographic Prints arranged by the Rontgen Society in the rooms of the Royal Photographic Society, which will be open daily (Sundays excepted), during June from 10 A.M. to 5 P.M.

Medical News.

UNIVERSITY OF CAMBRIDGE: *Diploma in Hygiene.*—The University of Cambridge, in response to a communication from the League of Red Cross Societies at Geneva, has established a new Diploma in Hygiene. In order that the scheme may assume an international aspect, it is hoped to bring together men representing the views of different countries—that is to say, candidates from advanced countries, such as America and Scandinavia, as well as those from the more recently reorganised nations of Eastern Europe, may avail themselves of the facilities provided in these classes. The training is primarily intended to benefit those who wish to familiarise themselves with English methods of sanitary science and practice and to return to their own countries *holding* an official certificate that they are qualified to act as officers of health. The diploma is open to candidates from all countries outside the British Dominions who possess a qualification to practise medicine or surgery *which, though not registrable in Great Britain*, is recognised by the authority of the country in which the candidate *practises.* The diploma is not registrable by the General Medical Council of Great Britain and Ireland. The full *course must extend over a* period of nine calendar months, and all candidates must have matriculated and resided in *the university for not less than two terms* or for one term and during a long vacation course. The examination is *divided into two parts and the requirements for* each part are similar to those demanded for the Diploma in Public *Health with the exception that no detailed* knowledge of English public health laws and statutes will be called for. It *appears to be more important that candidates should* become acquainted with the general principles of the *English code of sanitary legislation than that they should* possess a detailed knowledge of the legal duties and responsibilities *of our* sanitary authorities. *Arrangements are now* being completed to ensure lodging accommodation not only for D.P.H. *students*, but for the students who intend to take the diploma in hygiene.

The Secretary to the State Medicine Syndicate is Mr. J. E. Purvis, Public Health Laboratory, Cambridge.

MEDICO-LEGAL SOCIETY.—The annual general meeting will be held at 11, Chandos-street, Cavendish-square, London, W., on Thursday, July 7th (not Tuesday, June 28th, as previously announced), at 8.15 P.M. At 8.30 P.M. a paper will be read by Prof. A. Louise McIlroy on "Some Factors in the Control of the Birth-rate," which will be followed by a discussion. Lord Justice Atkin has been nominated by the Council of the Society as President.

FEDERATION OF MEDICAL AND ALLIED SOCIETIES.—The annual general meeting of the Federation will be held at 11, Chandos-street, London, W. 1, on Tuesday, June 28th, at 5.15 P.M., when the annual report of the Executive Council will be presented and the officers elected for the ensuing year. The President, Sir Berkeley Moynihan, will preside.

SOCIETY OF MEDICAL OFFICERS OF HEALTH: NAVAL, MILITARY, AND *AIR FORCE HYGIENE GROUP.*—A meeting of this group will be held at the house of the Society, 1, Upper *Montague-street, London*, W.C., on Thursday, June 30th, at 1.30 P.M. Colonel H. W. Grattan, Deputy *Director of Hygiene*, War Office, will read a paper on the Coöperation between Civil and Military Sanitary Authorities *during a* Grave National Emergency.

THE Research Defence Society will hold its annual general meeting on Wednesday, June 29th, at 3.30 P.M., at the *house* of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W. The chair will be *taken* by Lord Lamington. A short address will be given by Dr. H. H. Dale, F.R.S., on the work of the National Institute for Medical Research. Specimens will be shown. All interested are invited to attend.

ROYAL MEDICAL BENEVOLENT *FUND SOCIETY OF* IRELAND.—The annual meeting of this Society was held in the Royal College of Physicians on *June 15th, Sir James* Craig, the President, being in the chair. The amount given *in* grants during the year was £1201 10s., *as compared* with £1130 7s. 6d. last year. The amount received from branch treasurers showed an *increase of over* £88. There has been a marked increase in receipts from dividends and interest on investments—*£921, as compared* with £653 last year. Revenue from all sources for the year was £2915 6s. 11d., as compared with *£2530 12s. 8d.* in 1920, and the balance for this year is £1508 2s. 6d., as compared with £1275 1s. 8d. last year.

London Medical Exhibition.—The eleventh exhibition is arranged to be held in the Central Hall, Westminster, S.W., on Oct. 3rd, 4th, 5th, 6th, and 7th next.

Dr. Sidney C. Lawrence, after 15 years' tenure of the post, has resigned his appointment as Medical Officer of Health for Edmonton.

Mr. Henry P. Sturgis, upon his retirement from the post of chairman of the Royal London Ophthalmic Hospital, which he has held for the last 24 years, has been presented by members of the committee and medical staff with a handsome silver salver, as an expression of their appreciation of his services.

South London Hospital for Women.—A garden fête, pound day, and sale of work will be held to-day (Friday) from 3 p.m. Princess Helena Victoria has promised to attend and will receive purses. Tickets of admission 3 to 5 p.m. 2*s.*, after 5 p.m. 1*s.*, may be obtained at the hospital (South Side, Clapham Common, S.W.4) which will be open to inspection.

Royal College of Physicians of London.—At an extraordinary comitia held on June 15th, Sir Norman Moore in the chair, the resignation of his membership of the College by Jugalkisor Adhya was received and accepted. Sir Humphry Rolleston was appointed a representative of the College on the Court of Governors of the University of Sheffield in place of Dr. T. D. Acland. A resolution was passed to the effect that every candidate for the Conjoint Diploma should be required to produce evidence of adequate training in diseases of children and that the final examination should include examination in this subject.

Oxford Ophthalmological Congress, 1921.—The twelfth annual meeting of the Congress will take place on Thursday, Friday, and Saturday, July 7th to 9th next. The annual dinner of the Congress will take place in the Hall of Keble College at 7.45 p.m. on Thursday, July 7th. Members will meet informally at 7.45 p.m. on Wednesday, July 6th in the Hall of Keble College. The proceedings of the meeting will take place in the Department of Human Anatomy in the University Museum, kindly lent for the purpose by Prof. Arthur Thomson, and will consist of addresses, demonstrations, a scientific and a commercial museum. An outline of the programme is as follows: Thursday, July 7th: The Congress will be opened by the Master, Mr. Sydney Stephenson; at 10.5 a.m. a discussion on "The Causes of Infection after Extraction of Senile Cataract" will be opened by Dr. Victor Morax, of Paris. The following will take part in the discussion: Dr. A. Maitland Ramsay (Glasgow), Dr. T. Harrison Butler (Leamington Spa), Mr. John Hern (Darlington), Mr. E. H. E. Stack (Bristol), Mr. P. H. Adams (Oxford), Mr. Burdon-Cooper (Bath), Mr. Rayner D. Batten (London), Mr. N. C. Ridley (Leicester). The annual general meeting will be held at the conclusion of the discussion. During the afternoon the following will read papers: Mr. R. J. E. Hanson (London) "Stereoskopometry"—a suggested standard test; Mr. Arthur Greene (Norwich), Petrosal sinus sepsis; Dr. Wm. Wallace (London) Epidiascope demonstration of War Injuries of the Fundus, illustrated by water-colour drawings. On Friday, July 8th, in the Department of Human Anatomy, at 10 a.m., the Doyne Memorial lecture will be delivered by Mr. E. E. Maddox on "Heterophoria." 11 a.m., Dr. Charles Russ (London), An instrument which is set in motion by the eye—i.e., by vision, or by proximity of the human body—e.g., the hands. 12.30 p.m., Mr. John Hern (Darlington), Experiences of 606 and its substitutes in eye diseases. 2.30 p.m., at the Eye Hospital, Mr. N. C. Ridley (Leicester), the trench operation for chronic glaucoma, with account of cases: Dr. T. Harrison Butler (Leamington Spa), A plea for early diagnosis and operation in chronic glaucoma, with some remarks upon the treatment of acute glaucoma; Mr. P. H. Adams (Oxford), A modified operation for chronic glaucoma; Mr. B. Cridland (Wolverhampton), Some points in the performance of the Lagrange operation for chronic glaucoma. On Saturday, July 9th, in the Department of Human Anatomy: 10 a.m., Dr. T. Harrison Butler, Loss of vitreous during cataract extraction: 10.30 a.m., Mr. Percival J. Hay (Sheffield), Sight-testing with coloured test types; 11 a.m., Dr. Hamilton McIlroy (Glasgow), Some points of interest in the work of a school oculist. The Scientific and Commercial Museums will be open in the Department of Human Anatomy from 9.30 a.m. daily. Members who propose to be present are requested to send the attendance fee (one guinea) to the hon. secretary, Mr. Bernard Cridland, F.R.C.S. Edin., Salisbury House, Wolverhampton, at their earliest convenience, and at the same time to intimate whether they desire rooms reserved in Keble College, and their intention or otherwise to be present at the annual dinner.

Medical Golf Competitions.—*Medical Golfing Society:* The annual tournament was held on June 16th on the Walton Heath Golf Course. The day was very successful and the pleasure of the competitors was largely due to the excellent condition of the course. The results of the various competitions were as follows:—*The Lancet Cup*, open to members of the medical profession and given for the best scratch return against bogey: Winner, Mr. H. D. Gillies, 3 up. *Henry Morris Challenge Cup*, under handicap: Class A—1. Dr. C. E. Finny, 3 up: 2. Dr. J. A. Torrens, 2 up; last nine holes, Dr. Murray Thomson, 2 up. Class B—1. Dr. Eric W. Gandy, all square; 2. Sir Charles Ryall, one down; last nine holes, Dr. E. H. Shaw, 1 up. The Society will dine together at the Florence Restaurant, Rupert-street, London, on June 29th, and then discuss a proposed programme of inter-team matches. Members intending to be present should inform the hon. secretary, Dr. L. E. Creasy, 36, Weymouth-street, W.1.

Ladies' Medical Golfing Society: A most successful meeting was held on June 15th at Beaconsfield Golf Club. In the morning a medal round under handicap was played; the senior division prize was won by Miss Edith Adams after a tie, with a net score of 79, and the junior prize, presented by Mrs. W. F. Pedler, was won by Mrs. Alfred Eddowes, also after a tie, with a net score of 78. The Canny Ryall Challenge Cup for the best net return was won by Mrs. Arthur Moore with a score of 77. The prizes offered by Mrs. A. Currie for the best eclectic score sent in by a pair of competitors playing together, under half combined handicaps, were won by Mrs. de Paula and Mrs. Beatty Smyth. In the afternoon a foursomes versus bogey competition over ten holes resulted in a win for Mrs. T. Watts Eden and Dr. Joan Ross, who were one down. The success of the meeting was largely due to the efforts of the hon. secretary, Mrs. Laming Evans, to whom at the close of the meeting a hearty vote of thanks was accorded.

Prospective Candidate for the Scottish Universities.—At meetings of the Unionist Associations of the Scottish Universities held recently a letter was received from Sir Watson Cheyne, one of the members for the universities, stating that he had definitely decided not to seek re-election, and requested that a suitable prospective candidate should be selected without delay. In view of this letter Sir George Andreas Berry, LL.D., F.R.S.E., a former president of the Royal College of Surgeons, Edinburgh, and of the Ophthalmological Society of the United Kingdom, was invited to become prospective Unionist candidate, and he has agreed to place his services at the disposal of the constituency. Sir George Berry was educated at Marlborough and Edinburgh University, and also studied in London, Paris, Copenhagen, Vienna, and Giessen. He was from 1882 to 1905 ophthalmic surgeon, Edinburgh Royal Infirmary, where later he acted as one of the managers, and he has been for the past ten years a member of the University Court of the University of Edinburgh. During the war, and for one year after the war, he served as chief of the ophthalmic department of the Second General Hospital. He was knighted in 1916 in recognition of his scientific work.

Royal Medical Benevolent Fund.—At the last meeting of the Committee, held on June 14th, 27 cases were considered and £382 voted to 23 of the applicants. The following is a summary of some of the cases relieved:—

Widow, aged 50, of M.R.C.S. who practised in Clevedon and died in 1917. On the death of her husband applicant resumed her profession as a nurse, but, unfortunately, her health gave way and she cannot work continuously. Her daughter, aged 20, is apprenticed to a photographer but is not able to keep herself. Applicant receives £50 interest on War Loan and her fees for nursing amounted to £20. Rent of flat £60. Voted £10 in two instalments.

Widow, aged 42, of M.B. Dublin who practised in Plymouth and died in 1915. Applicant had nervous breakdown two years ago and sold her furniture to pay expenses, and it is only within the last few months that she was well enough to try to support herself and children. She hopes to get a house so that she can take boarders. A friend promised to share the furnished flat she now has, but owing to this arrangement falling through she has to find the whole rent—£3 3*s.* per week. Applicant managed to let one of the rooms for the last three months at 30*s.* per week including meals. She receives £25 subscribed by medical men and invested with the Public Trustee, £30 from Devon and Exeter Medical Society, and £50 from a brother-in-law. Owing to insufficient means she has had to take her daughter away from her art studies, the two younger children are at home and the boy at Epsom. Applicant earned £15 by knitting jumpers. Voted £18 in two instalments.

Daughter, aged 67, of M.R.C.S.Eng. who practised in Portsmouth and died in 1878. Three daughters were left to support themselves; one died recently who helped with the house. Their sole income is derived from letting apartments. Applicant and her sister, owing to indifferent health, find the work very trying. Mortgage and rates amount to £53 per annum, and by letting they received £3 3*s.* per week, including part board for one. In 1910 and 1911 the Fund helped this case to the extent of £22. Voted £18 in 12 instalments and a special grant of £6.

Widow, aged 63, of L.R.F.P.S.Glasg. who practised at Paignton and afterwards as a ship's doctor. When the war broke out applicant's husband went as a surgeon on transports engaged by different shipping companies, and not coming directly under the Admiralty was not entitled to a pension. Applicant is an invalid. Her son allows her £1 per month; the youngest daughter is out as a cook but unable to help her mother financially. Voted £12 in 12 instalments.

Daughter, aged 70, of M.R.C.S.Eng. who practised at Durham and died in 1860. Applicant is asking help towards increased rent and rates. Owing to limited accommodation not more than four lodgers can be taken and the rent received from them amounts to £170. Applicant also receives £25 from the Governesses Benevolent Institution. The Fund helped a sister in 1915 to the extent of £5. Voted £18 in 12 instalments.

Widow, aged 45, of L.S.A.Lond. who died in 1921. After paying funeral expenses and debts out of the insurance of £100 applicant had so little left that she applied to the Public Trustee for an advance of £20 pending the settlement of her father-in-law's estate, which is expected to realise about £60 per annum. The eldest girl is a lady-help earning 14s. per week and board, the youngest is undergoing three months' training as a shorthand-typist, the fees being paid by a neighbour. Voted £10.

Daughter, aged 36, of L.R.C.S.Edin. who practised at Hastings. Applicant has supported herself by literary work, but owing to a nervous breakdown has been unable to carry on work and was dependent on friends. She came under the notice of the C.O.S., who applied to the Fund on her behalf. She was found very ill and near starvation. Another society sent her away for six weeks to regain strength and ask for a grant towards the cost. Voted £15.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters J. Symonds, C.B., F.R.C.S., at 11, Chandos-street, Cavendish-square, London, W. 1.

Dr. D. J. Galloway has been appointed an unofficial Member of the Legislative Council of the Straits Settlements.

Hôpital St. Antoine, Paris.—A week's course on diseases of the digestive system will be given by Drs. Bensaude, Félix Ramond, and Le Noir from July 11th to 18th, at 10 A.M. and 3 P.M. Practical demonstrations will be given each day after the discussions; those attending these demonstrations must register under Dr. Le Noir, Salle Arant. Fee for the course, 100 francs.

East African Campaign Dinner.—A reunion dinner for all who took part in the East African Campaign will be held at the Holborn Restaurant on Friday, July 1st, when General Smuts will be the guest of the evening. Many who served in the R.A.M.C. in that campaign may be glad of this opportunity of meeting their late Commander-in-Chief on the occasion of his first visit to England as Prime Minister of the Union. Further particulars may be obtained from the Hon. Sec., 20, St. Thomas's Mansions, London, S.E.

Irish Medical Association.—The annual meeting of this Association was held on June 15th in the Royal College of Surgeons, Dublin, Dr. E. Magennis, the President, in the chair. The annual report of the Council stated that in the year 1920 the membership increased from 677 to 681. During the year the Treasury had agreed to the following remuneration for medical attendance on the Royal Irish Constabulary: (a) 2s. per head a month; (b) an addition of 6d. per head a month in respect of men stationed more than two miles from the doctor's house: (c) the rates to apply to the whole of Ireland from July 1st, 1920. The obligation to attend wives and children of constables has been abolished, and the new rates are therefore a substantial improvement on the old. It was noted that the Post Office had declined to increase the rate of remuneration (13s. a year) for attendance on postal servants. The Midwives Board for Ireland, as the result of the representations made by a deputation of the Council, had adopted an amended scale of fees for doctors summoned by midwives under the Midwives (Ireland) Act. The scale is as follows: (i.) Attendance at confinement in the day-time (8 o'clock, A.M., to 8 o'clock, P.M.) £2 2s. (ii.) Attendance at confinement in the night-time (8 o'clock, P.M., to 8 o'clock, A.M.) £3 3s., with the addition in each case of a mileage rate of 9d. for the portion of the outward and return journeys beyond three miles from the doctor's residence—no locomotion expenses to be allowed where the distance from the doctor's residence to the patient's house is under three miles. The annual statement of accounts shows a balance in hand of £163 19s. 6d., as against £581 3s. 10d. at the beginning of 1920. The President, in his address, alluded to the probability that the Association would be compelled to increase its subscription from one guinea perhaps to three. A discussion took place regarding the question of the fee paid for examination for life insurance. Representations had been made last year to the principal companies pointing out that the fee of one guinea was inadequate and demanding an increase. The companies, in view of their agreement with the British Medical Association that the fee should be one guinea, had declined to pay more. The Association passed a resolution asking the Irish Medical Committee to take steps to organise the profession of Dublin on the question.

The P. & O. Steamship Company has subscribed £1000 per annum for three years to Lady Minto's Indian Nursing Association towards the cost of passages for nursing sisters.

St. Thomas's Hospital Jubilee.—On June 21st the Jubilee of St. Thomas's Hospital was celebrated, the present buildings having been opened by Queen Victoria on June 21st, 1871. A jubilee appeal for £100,000 was made to clear the hospital of debt, and £2000 given or collected by the nursing staff was handed to the Duke of Connaught, President of the hospital, who presented the prizes to students of the medical school.

Committee on International Hygiene.—Following a suggestion of the Washington Conference to appoint an advisory committee of experts on industrial hygiene, the International Labour Office has invited the Governments of Belgium, France, Germany, Great Britain, Italy, Japan, the Netherlands, Spain, Sweden, and Switzerland each to nominate as a member of this advisory committee one of their health inspectors or factory inspectors.

The Children's Country Holidays Fund.—Mr. Percy Simmons, chairman of the London County Council, has issued an appeal on behalf of the above Fund. "For many years," he says, "by means of the Fund, a large number of the children attending the London elementary schools have been enabled to obtain a fortnight's holiday in the country, and this has been of the greatest value to them in every way. The position this year is particularly difficult owing to lack of funds and the increase in railway fares, while unemployment and short work make it impossible for the parents to contribute as much as they have done in past years." Cheques, &c., should be made payable to the Children's Country Holidays Fund, and should be sent direct to the Secretary at 18, Buckingham-street, London, W.C. 2.

Donations and Bequests.—The late Sir Felix Semon, K.C.V.O., M.D., F.R.C.P., bequeathed the whole of his laryngological library, except copies of his own writings, to the Royal Society of Medicine.—By will the late Mr. Daniel de Pass, of Old Court Mansions, Kensington, and Worthing, left £1000 each to the London Hospital, Dr. Barnardo's Homes, and the London Jewish Hospital, Stepney Green; £500 to the Beth Holim Hospital; and £100 each to St. Mary's Hospital, Paddington, the Jewish Deaf and Dumb Society, and the Worthing Hospital.—The late Mr. John Butt, of the Barnlands, Littlehampton, bequeathed £1000 to the Littlehampton and District Hospital; £300 to the Royal West Sussex Hospital, Chichester; £200 each to the Sussex Eye Hospital, the Sussex County Hospital, Brighton; and £100 to the Littlehampton Parish Nurses' Fund.—By will Mr. William Henry Fox, B.A., of Bradwell-grove, near Burford, left £1000 to the Burford Cottage Hospital and £2500 to the Radcliffe Infirmary.

Obituary.

WILLIAM ABRAHAM BELL, M.B. CAMB.

Dr. W. A. Bell, whose death at advanced age was recently announced, was born in April, 1841, the only son of Dr. William Bell, a well-known homœopath, of Hertford-street, London. Educated at Ipswich Grammar School and at Trinity Hall, Cambridge, he took a first class in the Natural Science Tripos, and in 1866 graduated in medicine. On his after career we have received the following interesting note from Dr. Robert Lee, who preceded him as a student by one year at St. George's Hospital. Dr. Lee writes: "As father and son could not agree on the question of medical practice, it was arranged that the son should go out to America to study. There he joined an important expedition to San Francisco, and after two years settled at Pike's Peak, Colorado, retiring from professional work. He became chief agent for development in Europe of interests in the American Railway and the lands that came under its control, and his house in Colorado was well known to Kingsley, Flower, and other scientific men who went out from our universities to explore the Western States."

Dr. Bell married in 1872 Clara Georgina Whitmore, daughter and co-heir of Whitmore Scovell, of Waddon, Surrey, by whom he had one son and three daughters.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

National Health Insurance Bill.

Sir A. MOND, Minister of Health, has introduced in the House of Commons the National Health Insurance Bill. Clauses 1 and 2 of the measure are based on the recommendations of the recent Departmental Committee on Approved Societies' Administration Allowance. No change is made in the rates of contribution or normal rates of benefit under the National Health Insurance Acts, but in order to enable the administration allowance for approved societies to be increased from 4*s.* 5*d.* to 4*s.* 10*d.* per member per annum the Bill proposes to make a small reduction in the amount retained out of each weekly contribution for the purposes of the Contingencies Fund, thus leaving a greater amount in the general funds of the societies out of which the administration allowance is provided. The proportion of two-ninths of the cost of benefits and administration to be provided by the Exchequer remains unaltered. The Exchequer is enabled to reduce or suspend its contribution of £150,000 a year to the Central Fund *pari passu* with the contribution thereto from the Societies Contingencies Funds. Clause 2 provides for the contribution from the funds of approved societies towards the administration expenses of insurance committees being increased by twopence per member per annum with a corresponding relief to the Exchequer. Clause 3 enables a reduction to be made in the membership of insurance committees in England and Wales with a consequent saving in the administration expenses of the committees while retaining so far as practicable the present proportions between the several classes of persons to be appointed. The net saving to the Exchequer under the Bill will, it is stated in the memorandum, be about £300,000 a year as from Jan. 1st last.

HOUSE OF LORDS.

THURSDAY, JUNE 16TH.

The Dentists Bill.

The Earl of ONSLOW, in moving the second reading of the Dentists Bill, explained the provisions of the measure, and said that it made no charge on the Exchequer. The expenditure would be defrayed from fees, and if there was any surplus it would be spent on dental education and research. There was only one point of substance about which there was any difference, and that was in regard to the form of the register. The admission of the unqualified practitioner had been regarded with some misgiving by Sir Frank Colyer, and a different form of register had been suggested. The matter had been discussed at considerable length and Sir Frank Colyer's points had been answered by the Chairman of the Departmental Committee, Mr. Acland. The Government supported the view of the Committee. The British Dental Association had forwarded to the Ministry of Health a memorial extensively signed by dental practitioners in favour of the Bill.

Lord GREVILLE said he did not wish their lordships to think that this was altogether an agreed Bill. There was, in fact, considerable opposition to a certain part of the measure, and on behalf of the Ivory Cross Society, of which he was at present the Chairman, he should have something to say in the Committee stage. There was no opposition to the Bill as a Bill by dental practitioners or the Society. It was, in fact, welcomed by dental practitioners and by his organisation, but there were certain features of it to which they strongly objected, principally in regard to the wholesale admittance of the unqualified practitioner.

The Marquess of SALISBURY said there was certainly an element in the Bill which would have to be carefully scrutinised in Committee. They were all in favour of the Bill and of protection for the dental profession, but there were not enough dentists to supply the population, and it was evidently proper that they should do all in their power to make the profession as attractive as possible. In order to arrive at an agreement the Committee seemed to have been led as a *quid pro quo* to the unqualified practitioners to admit the existing ones *en bloc* as fully qualified dentists. That might be good tactics from a Parliamentary point of view, but it was extremely bad from the point of view of the people who suffered from toothache, and they would have to consider closely whether they were going to allow a number of practitioners, some of whom were little better than charlatans, to be admitted by a stroke of the pen to the full advantages, privileges, and dignities of dentists in order to facilitate the passage of the Bill. There might be an answer, and if it was a good one, of course they would bow to it, but as at present advised he thought the Government should carefully consider whether a change in the Bill in this respect ought not to be made.

Viscount KNUTSFORD, a member of the Departmental Committee, said there was no suggestion that all unregistered men should be admitted *en bloc* to the register. On the contrary, they limited the admission of them to those men who had been in good practice for five years and could bring evidence of good character in that practice. Those men who had not been five years in practice, but who would submit themselves to a qualifying examination were also to be admitted. They had all received letters and circulars from a certain number of gentlemen, more noisy than wise, who wished to keep out all the unqualified men from the register. By far the greater part of the dental work in this country was done now by these unregistered men, and it would be a monstrous thing to prevent them carrying on their practice altogether. Moreover, the dental work of the country could not be done unless they were allowed to practise. It had been suggested that a special list of these men might be made. A much better plan would be that the Dental Register should show the qualifications of the dentist opposite his name, and that those who were unregistered, or were on the register without qualification, should have that fact shown opposite their names, in brackets. He ventured to think, however, that not a single member of that House had ever looked at a register to see what degrees his dentists had obtained; it mattered very little. But the fact of a dentist being on the register meant that he was obliged to obey the ethics of the profession; he was not allowed to canvass or advertise for work. The register, therefore, was not only a privilege, it was a controlling influence. Unless the Bill passed a good many men would not join the dental profession. Why should a father allow his son to join that profession when he knew that the butcher, the baker, or the candlestick maker might take a house next door and practise equally with him?

The Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 15TH.

Pre-war Disability Pensions.

Viscountess ASTOR asked the Financial Secretary to the Admiralty what conclusions had been reached with regard to increases in the pre-war disability pensions of men who served again in the war.—Mr. AMERY replied: It has been decided that the claims of pre-war disability pensioners who served during the war and were demobilised are to be dealt with under the post-war scales of pension. It is anticipated that the scales will shortly be promulgated, the final details being now in course of settlement.

Disabled Men and Unemployment Contributions.

Mr. ROBERT YOUNG asked the Minister of Labour whether an ex-Service man totally disabled was entitled to any refund of contributions paid by him into the funds governing unemployment under the National Insurance Acts.—Dr. MACNAMARA replied: An ex-Service man totally disabled is not entitled on the ground only that he is totally disabled to any refund of employment contributions correctly paid under the National Insurance Acts. The only provision for a refund to an insured contributor of contributions correctly paid is contained in Section 25 of the Act of 1920, under which a contributor may obtain a refund upon reaching the age of 60, provided that certain conditions are satisfied. A person who is in receipt of a pension of £26 or upwards, is, however, entitled under Section 3 of the Act to exemption from liability to be insured. This would relieve him, but not his employer, from payment of contributions.

Unemployment Benefit and Treatment Allowances.

Mr. TYSON WILSON asked the Minister of Labour if he was aware that, when an ex-Service man who was or had been in receipt of treatment allowance was certified by the medical referee as fit for employment, his treatment allowance ceased immediately; that if he had no employment to go to he cannot make application for unemployment benefit for at least seven days after the receipt of the last treatment allowance; and that this meant that these men were sometimes without any income for two or even three weeks; and whether he could, by regulation or otherwise, make arrangements whereby unemployment benefit could be paid them seven days after the stoppage of treatment allowance.—Dr. MACNAMARA replied: A claimant for unemployment benefit must, amongst other things, be capable of and available for work. Accordingly, an ex-Service man who has been in receipt of full treatment allowance on the ground that he was incapable of work, would not be in a position to claim benefit during the period covered by the treatment allowance. Treatment allowances are paid in advance up to Tuesdays; unemployment benefit, which is necessarily due only after proof of unemployment has been given, is paid on Fridays in respect of weeks ending Wednesdays. Accordingly there is a period of 16 days between the last day on which treatment allowance is actually paid and the first day on which benefit is received. The first seven of these days will be covered by the last payment of treatment allowance paid in advance. I may further point out that this class of man is almost invariably entitled to a pension and that payment of pension in advance, which is, of course, suspended during full treatment allowance, is, or ought to be, resumed immediately on cessation of treatment allowance.

Polluted State of the River Lee.

Major MALONE asked the Minister of Health whether he would have inquiry made by his department into the polluted and offensive state of the River Lee; whether he was aware that complaints had frequently been made to the local authorities by the inhabitants and persons using the river, and that, as late as last week, the medical officer of health for Tottenham reported to his committee that objectionable matter consisting of decomposing organic material and an oily substance entered the River Lee below the Tottenham lock, causing that reach of water to be highly polluted and offensive, and would he exercise such pressure on the Lee Conservancy Board as to compel that authority to purify the river in the interest of the health of the inhabitants and the users of the river.—Sir ALFRED MOND replied: The Lee Conservancy Board are by virtue of Section 9 of the Rivers Pollution Prevention Act, 1876, the authority for enforcing the provisions of that Act and of the Lee Conservancy Act, 1868, with regard to the River Lee, and I have no power to compel the Board to take action in the matter. I have no information as to the complaints referred to in the second part of the question.—Major MALONE: In the interests of the health of the district and in view of the complaints that have been made has not the right honourable gentleman power to compel the Board to carry out this work?—Sir ALFRED MOND: No, Sir, I have not.

Remuneration of Bramley Vaccination Officer.

Mr. ROBERT RICHARDSON asked the Minister of Health whether his attention had been directed to the case of Mr. Arthur Gaunt, vaccination officer of the Bramley Union, and the definite attempt of the Bramley guardians to deprive an official of 20 years' service of his living by taking away the bonus entirely, leaving this officer the sum of £25 9*s.* 7*d.* per quarter as his only source of income to maintain a wife and two children; and whether, under the circumstances, this was a case in which he would exercise his right of determining the amount of remuneration to be paid by the Bramley guardians.—Sir ALFRED MOND replied: I understand that the facts are as stated in the first part of the question except that as the officer in question is only a part-time officer, I am not able to say whether he has any other source of income. After full consideration of the circumstances of this case, I do not see my way to interfere with the decision of the guardians in a matter affecting the salaries of their officers.

The Criminal Law Amendment Bill.

Viscountess ASTOR asked the Lord Privy Seal whether he had received copies of two resolutions passed at a meeting held in the House of Commons in support of the Bishop of London's Criminal Law Amendment Bill, at which practically every organisation interested was represented, promising to abstain from introducing controversial amendments; and whether, under these circumstances, he would undertake to give facilities for the passage of the Bill this session.—Mr. CHAMBERLAIN replied: The answer to the first part of the question is in the affirmative. I cannot, however, at present add anything to the answer which I gave my honourable friend on April 12th last.—Viscountess ASTOR: Since that answer we have had a meeting, and as this is not a controversial question could not the right honourable gentleman really see his way to make time for it as it will cost the country nothing? It is one of those Bills which the Government could get through. It would do a great deal of good, and I would urge the right honourable gentleman to find time for it.—Mr. CHAMBERLAIN: I quite understand the importance attached to this measure by a very large section of public opinion, and I am anxious that it should be considered by the House this session, but I cannot make a pledge to find time for it at this stage, though I hope it may be possible to do so later.—Major C. LOWTHER: Is the right honourable gentleman aware that this Bill would be by no means uncontroversial and that it is likely to lead to considerable controversy?—Viscountess ASTOR: Only by a certain section.

Old Age Pensioners in Poor-law Infirmaries.

Mr. NEVILLE CHAMBERLAIN asked the Minister of Health, whether an old age pensioner ceased to be entitled to receive his pension on entering a Poor-law infirmary on the ground that the cost of his maintenance was borne by the institution so long as he was an inmate; and, if so, on what ground the pension was stopped in cases where the cost of maintenance was borne by relatives or friends of the pensioner.—Commander HILTON YOUNG (Financial Secretary to the Treasury) replied: In the former case Section 3 (1) of the Old Age Pensions Act, 1919, provides that an old age pensioner shall not be disqualified for the receipt of a pension during a period of three months from the date of entering an infirmary if he so long continues to require medical or surgical treatment. After that period he incurs disqualification. In the latter case the pensioner ceases to be entitled to a pension so soon as his means, which include the cost of maintenance borne by relatives or friends, exceed the statutory limit of £49 17*s.* 0*d.* per annum.

Pensions (Ill-health) Claims.

Sir ROBERT CLOUGH asked the Minister of Pensions whether claims were admitted on the part of soldiers who did not, on demobilisation, make complaint of ill-health, either because they did not themselves then recognise the gravity of the symptoms or because there were actually at the time no specific symptoms of the disease whose origin arose from the war, but which only developed subsequently.—Major TRYON (Parliamentary Secretary to the Ministry of Pensions) replied: The answer is in the affirmative.

Medical Referee and ex-Soldier's Claim

Lieut.-Colonel HURST asked the Minister of Pensions whether he was aware that the Appeal Board had refused to revise the case of F. J. Taylor, 55, Jenkinson-street, Manchester, and had maintained a 20 per cent. assessment; whether this refusal was in harmony with the report of the medical referee; whether he was aware that this ex-soldier still had a bullet lying immediately to the left of his heart; and if he would have the case inquired into.—Mr. MACPHERSON replied: I am having inquiries made in this case, and hope to communicate with my hon. and gallant friend in a few days.

Lunacy Act Regulations.

Colonel WEDGWOOD asked the Minister of Health how soon he proposed to have posted up in the waiting-rooms of public asylums the provisions of Section 79 of the Lunacy Act, 1890, which had hitherto been hidden from the friends and relatives of patients.—Sir ALFRED MOND replied: The Board of Control have notified all visiting committees that they propose to make a rule requiring the inclusion of the substance of this Section in the "Regulations as to Visitation" furnished by all asylums to the friends of patients. There is, however, no foundation for the suggestion contained in the last part of the question.

Certification of "Voluntary Boarders."

Colonel WEDGWOOD asked the Minister of Health whether the Lunacy Board of Control had recently issued a regulation putting a stop to the certification of voluntary boarders while inmates of licensed houses or registered hospitals; and, in view of the fact that no procedure for certification had been prescribed by the Lunacy Act of 1890 applicable to the circumstances of such boarders, would he say what had been the nature of the steps required to be taken under Section 20 of the Act of 1891, when certification had hitherto been directed by the Board.—Sir ALFRED MOND replied: The hon. and gallant Member is under a misapprehension and no such regulation has been issued. No steps have been taken by the Board and none are needed to give effect to Section 20 of the Lunacy Act, 1891. The methods of certification are laid down in the Acts.

Medical Officers and Examination of ex-Service Men.

Mr. ALFRED T. DAVIES asked the Minister of Pensions what proportion of medical men whose services were used in examining ex-Service men had had experience overseas during the war; and whether he would consider the desirability of the employment of a larger number of such medical men in the interests of those so examined from time to time.—Major TRYON replied: Approximately 60 per cent. of the medical officers employed by my department in the examination of ex-Service men have served overseas. It is the practice of the Ministry, other things being equal, to give preference to medical men possessing the qualification to which my hon. friend refers.

THURSDAY, JUNE 16TH.

Permits for Bellahouston Hospital.

Mr. NEIL MACLEAN asked the Minister of Pensions whether, although permits to enter Bellahouston Hospital and interview cases had been granted to the British Legion, the Association for the Limbless, and the New Advisory Committee by the Scottish Regional Director, a permit for a similar purpose had been refused to the representative of the International Union of Ex-Service Men; what was the reason for this refusal; and whether he would issue instructions that equal facilities given to other ex-Service men's organisations would also be granted to the International Union of Ex-Service Men.—Mr. MACPHERSON replied: The hon. Member appears to have been misinformed. No such permits have been issued to any of the bodies mentioned, and the remainder of the question, therefore, does not arise.

Pensions Administration in Glasgow Area.

Mr. Neil Maclean asked the Minister of Pensions whether he was aware of the public dissatisfaction in Glasgow in the administration of the war pensions in the Glasgow area; that there was a feeling that the regional officers were giving rulings which were at variance with the decision of the local war pensions committee, and that the local war pensions committee resigned because of the difficulties created by these rulings: and whether he was prepared to have a full inquiry into the administration of the war pensions committee for the Glasgow area.—Mr. Macpherson replied: The answer to all parts of this question is in the negative.

Local War Pensions Administration.

Mr. Lawson asked the Minister of Pensions, whether it was the policy of the Ministry to transfer the powers of local pension committees to the areas, so that the work carried out by these committees would in a short time be undertaken by permanent officials of the Ministry.—Mr. Macpherson replied: My hon. friend may remember that the working of the local committee system was specifically included in the terms of reference to the Departmental Committee of Inquiry which I appointed last November. Until the report of that Committee is in my hands I do not propose to make any statement.

Appointments of Medical Referees.

Mr. John Guest asked the Minister of Pensions (1) whether, seeing that the original appointments of medical referees were made before the completion of medical demobilisation, these appointments would now again be declared vacant and re-advertised, or whether the original appointments were the fixed and permanent appointments of the present holders; (2) whether the appointment of medical referees were now reviewed every six months as originally decided; how many of these appointments had been considered vacant on review and changed; and whether the opinion of the local pensions committee was ever asked or considered in these appointments.—Mr. Macpherson replied: In the latter part of 1919, when the demobilisation of medical men was practically complete, the then existing appointments of medical referees, to the number of 962, were declared vacant, and 1553 new appointments were made, preference being given to those men who had served overseas during the war. All the present appointments are temporary, being subject to one month's notice on either side. While the paramount consideration in making these appointments must be medical, consideration is always given to representation made by local committees.

Cost of Medical Referees.

Mr. Guest asked the Minister of Pensions what was the total number of medical referees employed locally and centrally on pensions work; what was the total cost to the country; what fees were now paid for this work; what was the average per claimant pensioner: and whether all the appointments were part-time.—Mr. Macpherson replied: The Ministry utilises the services of 1717 medical referees, whose appointments are part-time and subject to a month's notice. Payment is made at the rate of 5*s.* per case except where the examination is in connexion with a claim to alternative pension, when the fee is 10*s.* 6*d.* The amount paid in fees to medical referees during the last financial year was approximately £250,000.—Sir W. Pearce: Is there a transfer of duties formerly performed by war pensions committees to the medical referees?—Mr. Macpherson: I do not think so. They deal purely with the medical aspect of a case and the local pension committees deal mainly with the facts.

Medical View of School Camps.

Mr. Trevelyan Thomson asked the President of the Board of Education whether, notwithstanding the recommendations of the chief medical officer that school camps should be encouraged, local education authorities were handicapped in making such arrangements under Section 17 of the Education Act of 1918, owing to the rulings of his Board that attendance at lessons given in camps could not be reckoned on the register of attendances if any charge was made; and, if the Act of 1918 prohibited such charges, would he bring in an amending Bill to enable local education authorities to organise school camps for which a charge was made and where attendance at lessons might be counted on the school register.—Mr. Herbert Lewis replied: On the general question of principle I can only refer the hon. Member to the answer which was given to him on April 26th. I do not consider that local education authorities are handicapped, and I am not prepared to introduce legislation for the purpose suggested.

Death-rate among Miners.

Mr. Robert McLaren asked the Secretary for Mines whether his attention had been called to the report published by the Chief Inspector of Mines, and could he explain why the death-rate per 1000 persons employed in 1920 was 0·88 and in 1914 1·08, whereas the amount of mineral produced per death was 217,259 tons and 228,947 tons for 1920 and 1914 respectively; and whether, in the opinion of the department, the mines were safer now than in 1914.—Mr. Bridgeman replied: The explanation of the phenomenon that while the death-rate per person employed has fallen the death-rate per mineral produced has risen is, of course, that the fall in the death-rate is not proportionate to the fall in output. As regards the last part of the question, my hon. friend is aware that it is the constant endeavour of my department to bring about greater safety in mining, but it is obvious that progress cannot be tested by a comparison of the figures of two isolated years.

Ex-Service Men and Lunacy Regulations.

Mr. Frederick Roberts asked the Minister of Health whether, when an ex-Service man had been committed to an asylum on account of mental injury attributable to the war the man himself and his next-of-kin were informed that one of the privileges attached to his having been placed on a private patient footing was that, provided that he could not be proved to be dangerous and unfit to be at large, his next-of-kin had the right, in accordance with Sections 72 to 74 of the Lunacy Act, to direct his discharge.—Sir Alfred Mond replied: It is not desirable to furnish this information on admission, but when a service patient is sufficiently recovered to raise the question of his discharge he is informed of the legal position and of the steps to be taken by his relatives.

Insured Man and Sanatorium Treatment.

Mr. Grundy asked the Minister of Health if he was aware that Frederick Shoesmith, of 9, Cator-street, S.E. 15, had been an inmate of Camberwell Infirmary for several months, that he was an insured person, and as such had been recommended for sanatorium treatment; and what steps he proposed to take to obtain the benefit expected by this man.—Sir Alfred Mond replied: I understand that an application for sanatorium benefit was received by the London Insurance Committee on April 12th last from this man, who was at the time an inmate of the Camberwell Infirmary; that the case is one of advanced tuberculosis, and that Mr. Shoesmith was not therefore recommended for treatment in a sanatorium. I am informed, however, that the case may be suitable for admission to a hospital for the treatment of advanced cases of this disease. Consequent upon the termination of sanatorium benefit on April 30th last the Insurance Committee ceased on that date to provide institutional treatment for tuberculosis, and the question of the provision of such treatment is now a matter for the London County Council. There is considerable pressure upon the available accommodation for the treatment of advanced cases of tuberculosis in London at the present time, but I will communicate with the County Council with regard to this case.

MONDAY, JUNE 20TH.

Death Sentence for Infant Murder.

Mr. Henry McLaren asked the Secretary for the Home Department whether he had received representations in reference to the sentence passed on a girl named Roberts convicted of the murder of her infant child at Hinckley; and whether, in view of the feeling aroused by the passing of the death sentence in such cases, he could see his way to introduce into the House of Commons a Bill giving discretionary powers to the judge to pass a sentence other than death.—Mr. Shortt replied: The answer to the first part of the question is in the affirmative. I will send the honourable Member a draft of a Bill dealing with this matter which was agreed to by the Lord Chancellor, the Lord Chief Justice, and the Attorney-General in 1910. If a Bill on those lines were introduced and proved to be uncontroversial, I think it might be passed.

The Sinking of Hospital Ships.

Mr. Bottomley asked the Prime Minister whether any person connected with the German submarine naval command was to be brought to trial for the issue of orders to submarine commanders to sink hospital ships; and, if not, was the British Government a party to this arrangement.—Sir G. Hewart (Attorney-General) replied: As already stated the trials which have taken place and are to take place immediately are of cases upon the Allies' preliminary list. It is not in the interest of further proceedings to reply specifically to the first part of the question. No such arrangement as suggested has been entered into.

Medical Insurance Benefits.

Mr. Leonard Lyle asked the Minister of Health if he had any statistics showing the number of insured under the National Health Insurance Act who were already in arrears with the maximum total of unpaid subscriptions which, unless met before October, would debar them from medical benefits in 1922.—Sir A. MOND replied: *All insured persons remain entitled to medical benefit so long as they continue in insurance and there is no suspension of the* benefit on account of arrears of contributions.

TUESDAY, JUNE 21ST.

Washington Maternity Convention.

Major HILLS asked the Prime Minister whether the Government was prepared to submit a resolution embodying the hours of labour convention and the maternity convention to the House of Commons before July 27th, in view of the fact that, on that day, expired the time limit allowed under Article 405 in which to bring conventions before the competent authority for the enactment of legislation.—Mr. CHAMBERLAIN (Lord Privy Seal) replied: For details *as to the constitutional* issues involved, I would refer my honourable and gallant friend to the speech made by my right honourable friend the Attorney-General during the debate on Friday, May 27th. We are anxious, however, to give the House the fullest possible opportunity for discussion on these conventions. Such an opportunity was afforded during the recent debate, and, as I explained on Tuesday last, there will be a further opportunity for discussion so soon as the pressure of other business permits.

Milk Deficient in Fat.

Mr. HURD asked the Minister of Agriculture whether, in view of recent proceedings, he would consult the Minister of Health as to the issue of a circular letter to local authorities informing them that the basis of prosecutions for supplying milk deficient in fat should be not one or two tests made in *exceptional circumstances but a series of tests*, so that while detecting adulteration the farmer or dairyman might not be penalised for faults for which neither could be held responsible.—Sir A. BOSCAWEN replied: I am examining into such cases as my honourable friend has put before me of the prosecution of dairymen *in respect of the sale of milk* of poor quality. As I stated in my reply on June 16th, *I shall be prepared, if the body of evidence warrants it, to* consult with my right honourable friend the Minister of Health *with a view to the issue of a circular letter to local* authorities.

The Services.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. E. P. Hewitt retires on ret. pay.

Capt. T. K. Boney relinquishes the actg. rank of Maj.

Capt. H. G. Winter, M.C., relinquishes the actg. rank of Maj.

Temp. Capt. A. C. Profeit relinquishes his commn. and is granted the rank of Maj.

R. W. Harper, late temp. Capt., to be temp. Capt.

ARMY DENTAL CORPS.

Temp. Maj. J. G. Worsley, Dental Surg., from Spec. List, to be Maj.

Temp. Capt. A. V. Milnes, Dental Surg., from Gen. List, to be Capt.

SPECIAL RESERVE OF OFFICERS.

Capt. D. Clyde relinquishes his commn. on appt. to a permanent commn. in the Ind. Med. Service.

Capt. R. Magill relinquishes the actg. rank of Maj.

TERRITORIAL FORCE.

Lt.-Col. (Bt. Col.) T. H. Haydon resigns his commn. and retains his rank.

Maj. J. A. Kendall resigns his commn. and retains the rank of Maj.

Maj. T. Martin (late R.A.M.C.) to be Capt. and relinquishes the rank of Maj.

Capt. J. W. Kemp to be Maj.

Capt. H. E. S. Richards is secd. for service under the Colonial Office.

A. H. Crook (late Surgn. Lt., R.N.V.R.) to be Capt.

Capt. D. C. Graham (late R.A.M.C.) to be Lt. and relinquishes the rank of Capt.

Lt. *L. H. Taylor to* be Capt.

2nd Lond. Sanitary Co.—Lt. S. H. Kemp resigns his commn. and retains the rank of Lt.

DEFENCE FORCE.

To be temp. Majs.: Temp. Capt. O. Teichman (whilst specially empld.) and J. C. S. Burkitt.

Temp. Capt. R. M. Wilson relinquishes his commn.

To be temp. Capts.: A. H. Fullerton and M. H. Barton.

1st (Home Counties) Fd. Amb. (D.F.).—*To be temp.* Lt.-Col.: E. A. Houchin.

2nd (Home Counties) Fd. Amb. (D.F.).—G. A. Blake (Capt. (Bt. Maj.), R.A.M.C.) is granted the rank of temp. Lt.-Col. while *comdg. a Fd. Amb.*

1st (E. Lancs.) Fd. Amb. (D.F.).—R. MacKinnon (Capt., R.A.M.C., Spec. Res.) is granted the rank of temp. Maj.

1st (N. Midland) Fd. Amb. (D.F.).—A. E. Milner (Maj. is granted the rank of temp. Lt.-Col. while comdg. a Fd. Amb.

2nd (N. Midland) Fd. Amb. (D.F.).—To be temp. Lt.-Col.: G. B. *Gill*. To be temp. Maj.: T. C. Clare. To be temp. Capts.: G. R. Jackson and J. Donald. To be temp. Lt.: T. N. C. *Atkinson*.

3rd (N. Midland) Fd. Amb. (D.F.).—To be temp. Lt.-Col.: J. Miller. To be temp. Maj.: G. F. *Haycraft*. To be temp. Capts.: R. B. Lilly and W. W. Hallchurch.

2nd *(E. Ang.) Fd. Amb. (D.F.).—To be temp. Lt.-Col.:* S. J. Fielding.

3rd (E. Ang.) Fd. Amb. (D.F.).—To be temp. Lt.-Col.: C. S. Wink.

2nd (S. Midland) Fd. Amb. (D.F.).—To be temp. Lt.-Col.: R. A. Broderick. To be temp. Capts.: L. G. Parsons and H. W. Featherstone.

The undermentioned relinquish their commissions: Temp. Lt.-Col. R. A. Broderick. Temp. Capts. L. G. Parsons and H. W. Featherstone.

INDIAN MEDICAL SERVICE.

The King has approved the relinquishment of their commissions by the undermentioned:—

Temp. Capts. Gorur Srinivasmurti, Shyam Behari Lal, Vinayak Laxman Sathe, Armand Marcus Duarte, Christian John Prabhakar, Ram Lal Bhumbhwal, Vasadeo Bhanrao Gupte.

ROYAL AIR FORCE.

Squadron Leader *H.* B. Porteous is seconded for duty with the South African Air Force.

THE WAZIRISTAN OPERATIONS.

The following names appear in a long list of awards for services during the Waziristan Operations:—

Companion of the Star of India: Col. C. W. Profeit, C.M.G., D.S.O., A.M.S. (mentioned in despatches).

Companion of the Indian Empire: Col. T. Stodart, I.M.S., and Lt.-Col. (actg. Col.) C. Hudson, D.S.O., I.M.S. (mentioned in despatches).

Officer of the British Empire: Capt. (actg. Lt.-Col.) A. G. Biggam, R.A.M.C. (mentioned in despatches); Maj. T. C. C. Leslie, R.A.M.C. (mentioned in despatches); Capt. and Bt.-Maj. (temp. Maj.) J. A. Sinton, V.C. I.M.S. (mentioned in despatches); and Maj. G. S Wallace, R A.M.C.

To be Brevet Lt.-Col.: Maj. T. S. Dudding, O.B.E., R.A.M.C.

Bar to Military Cross: Capt. W. J. S. Ingram M.C., I.M.S.

Military Cross: Temp. Capt. Banwari Lall Gupta, I.M.S.; Temp. Capt. Kishan Ganesh Mohile, I.M.S.; Capt. (actg. Maj.) D. Reynolds, R.A.M.C.

Mentioned in Despatches: Maj. (actg. Lt.-Col.) J. Anderson, I.M.S.; Maj. D. Coutts, I.M.S.; Capt. Radha Krishna Dewan, I.M.S., T.C.; Maj. C. H. Fielding, I.M.S.; Capt. (actg. Maj.) R. E. Flowerdew, I.M.S.; Capt. C. C. Harrison, R.A.M.C., S.R.; Capt. Enathickal John Koshi, I.M.S., T.C.; Capt. (temp. Maj.) *H. H. Mulholland, R.A.M.C.; Capt. (actg. Lt.-Col.)* D. F. Murphy, I.M.S.; Lt. Attamahomed Tajmahomed Shaikh, I.M.S., T.C.; Capt. (actg. Lt.-Col.) C. H. Smith, O.B.E., I.M.S.; Capt. R. R. Thompson, M.C., R.A.M.C.; Capt. (actg. Maj.) Jagannath Balkrishna Vaidya I.M.S.; Capt. (actg. Lt.-Col.) J. P. Huban I.M.S.; *Temp. Capt. Nitya Nand Joshi, I.M.S.*; Maj. (temp. Lt.-Col.) N. M. Wilson, I.M.S.; Maj. (actg. Lt.-Col.) H. B. Scott, I.M.S.; Maj. (actg. Lt.-Col.) F. B. Shettle, I.M.S.; and Dr. Alice Pennel, Afghan Mission Hospital, Bannu.

The King has granted permission to *Dr. Kenneth Edward* Eckenstein to wear the Cross of Chevalier of the Legion of Honour and the *Cross of Chevalier of the Order of the Crown* respectively conferred upon him by the President of the French Republic *and the* King of the Belgians, in recognition of his services during the late war as medical officer in the *French Army.*

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

Thursday, June 30th.—Papers:—Sir J. J. Dobbie and Dr. J. J. Fox: The Absorption of Light by Elements in a State of Vapour; The Halogens. Prof. W. A. Bone and the late Mr. W. A. Haward: Gaseous Combustion at High Pressures. Part II., The Explosion of Hydrogen-Air and Carbon-Monoxide-Air Mixtures. Prof. A. E. H. Love and Mr. F. B. Pidduck: Lagrange's Ballistic Problem. Mr. J. Proudman: The Principles of Internal Ballistics (communicated by Prof. H. Lamb). Mr. R. H. Fowler: A Simple Extension of Fourier's Integral Theorem and some Physical Applications in particular to the Theory of Quanta (communicated by Sir Ernest Rutherford). Capt. D. Brunt: The Dynamics of Revolving Fluid on a Rotating Earth (communicated by Sir Napier Shaw). And other papers. The following papers will be read in title:—Takeo Shimizu: A Preliminary Note on Branched a Ray Tracks (communicated by Sir E. Rutherford.) Takeo Shimizu: A Reciprocating Expansion Apparatus for Detecting Ionising Rays (communicated by Mr. C. T. R. Wilson). Mr. R. W. Wood: The Time Interval between Absorption and Emission of Light in Fluorescence.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETING OF SECTION.

Monday, June 27th.

SECTION OF ODONTOLOGY: at 8 p.m.

Paper:—Mr. Kelsey Fry: The Dental Treatment of Congenital and other Perforations of the Palate.

RESEARCH DEFENCE SOCIETY: at the House of the Medical Society of London, 11, Chandos-street, Cavendish-square, W.

Wednesday, June 29th.—3.30 p.m., Annual General Meeting. Short Address:—Dr. H. H. Dale: Work of the National Institute for Medical Research. Specimens will be shown.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, June 27th.—12.15 p.m., Dr. Burnford: Pathological Demonstration. 2 p.m., Mr. Baldwin: Demonstration of Cases (Surgical Wards). Mr. MacDonald: Surgical Out-Patients. Dr. Morton: X Ray Department. 5 p.m., Lecture:—Mr. D. Armour: Diseases of the Gall-bladder and Ducts: Treatment.

Tuesday.—10 a.m., Mr. Steadman: Dental Department. 11 a.m., Dr. McDougal: Electrical Department. 2 p.m., Dr. Burnford: Medical Out-Patients. Dr. Pernet: Skin Department. 2.30 p.m., Mr. Addison: Visit to Surgical Wards. 5 p.m., Lecture:—Dr. Simson: Abortion.

Wednesday.—11 a.m., Mr. MacDonald: Demonstration of Cystoscopy. 12 noon, Mr. Sinclair: Surgical Diseases of the Abdomen. 2 p.m., Mr. Gibb: Eye Department. Mr. D. Armour: Visit to Surgical Wards. 5 p.m., Lecture:—Mr. Baldwin: Surgery of the Rectum.

Thursday.—10.30 a.m., Dr. Simson: Gynæcological Demonstration. 12 noon, Dr. S. Pinchin: Diseases of the Heart. 2 p.m., Mr. B. Harman: Eye Department. 2.30 p.m., Dr. Arthur Saunders: Demonstration of Cases (Medical Wards). 5 p.m., Special Lecture:—Sir Thomas Horder: The Investigation and Immediate Treatment of a Case of Acute Pyogenic Infection (open to all medical practitioners).

Friday.—10 a.m., Dr. Robinson: Gynæcological Operations and Visits to Wards. Dr. G. Stewart: Neurological Demonstration. 2 p.m., Mr. Banks Davis: Diseases of the Throat, Nose and Ear. 2.30 p.m., Dr. Pritchard: Visit to Medical Wards. 5 p.m., Lecture:—Mr. T. Gray: The Surgical Physiology of the Alimentary Tract.

Saturday.—10 a.m., Dr. A. Saunders: Medical Diseases of Children. 2 p.m., Dr. Owen: Medical Out-patients. Mr. Sinclair: Surgical Out-patients.

Daily:—10 a.m., Visit of Post-graduates to Wards. 2 p.m., In-patient, Out-patient Clinics and Operations.

LONDON HOSPITAL MEDICAL COLLEGE (University of London) Turner-street, Mile End E.

Courses of Lectures:—

Advanced Lectures in Physiology, to Students of the University and to others interested in the subject.

A Course of Eight Lectures on Reception of Sensory Stimuli, to be given by Prof. H. E. Roaf in the Physiology Theatre.

Thursday, June 30th.—4.30 p.m., Lecture VIII.

SURGICAL UNIT.—A Special Course of Ten Lectures on Advanced Surgery in the Unit Theatre to Post-graduates and Senior Students.

Tuesday, June 28th.—4.15 p.m., Mr. H. Lett: Stricture of the Urethra.

Thursday.—4.15 p.m., Mr. H. Lett: Retention of Urine.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

Thursday, June 30th.—4 p.m., Lecture:—Dr. Poynton: Pericarditis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Monday, June 27th.—10 a.m., Mr. W. E. Tanner: Surgical Out-patients. 2 p.m., Dr. A. J. Whiting: Medical In-patients. 2.30 p.m., Mr. J. B. Banister: Gynæcological.

Tuesday.—9.45 a.m., Lt. Col. R. H. Elliot; Eye Operations and Cases. 2.30 p.m., Dr. J. Metcalfe: X Ray Department. 3 p.m., Lecture Demonstration:—Mr. C. H. Hayton: Anatomy of the Pharynx and Larynx, with Methods of Examination.

Wednesday.—2 p.m., Mr. C. H. Hayton: Throat Operations. 2.30 p.m., Dr. W. J. Oliver: Dermatological. 3 p.m., Lecture Demonstration:—Mr. W. E. Tanner: Some Cases of Acute Bone Disease.

Thursday.—2 p.m., Mr. N. Fleming: Eye Department. 2.30 p.m., Mr. J. B. Banister: Gynæcological Operations. Dr. J. Metcalfe: Radiology.

Friday.—2 p.m., Dr. C. E. Sundell Diseases of Children. 3 p.m., Lecture Demonstration:—Dr. C. E. Sundell: Physiology of Digestion in Infants. 5 p.m., Dr. Provis and Mr. Benians: Venereal Department.

Saturday.—10.30 a.m., Mr. W. E. Tanner: Operations. 3 p.m., Mr. H. W. Carson: Surgical In-patients.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square, W.

Post-Graduate Course on Infant and Child Welfare.

A Course of Twelve Practical Demonstrations on the Management and Feeding of Infants and Young Children by Dr. E. Pritchard to Qualified Practitioners

Tuesday, June 28th.—10.30 a.m., Demonstration V., The Modification of Milk.

Thursday.—3 p.m., Demonstration VI., The Uses of Dried Milk and Patent Foods.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, E.

A Course of Post-graduate Clinical Lectures and Demonstrations in the Board Room of the Hospital, free to Medical Practitioners and Students of Medicine.

Tuesday, June 28th.—4 p.m., Mr. K. A. Lees: Chronic Otitis Media.

Thursday.—Mr. V. Nesfield: The Temporary Treatment of Acute Glaucoma by Paracentesis.

TAVISTOCK CLINIC FOR FUNCTIONAL NERVE CASES, 51, Tavistock-square, W.C.

A Course of Ten Lectures on Elementary Psychotherapy, to be given by Dr. H. C. Miller, at the Kingsway Hall, Kingsway, W.C.

Friday, July 1st.—5.15 p.m., Lecture IX.: Dream Interpretation (II.).

Appointments.

Graham, Lewis, M.S. Lond., F.R.C.S. Eng., has been appointed Honorary Obstetric Officer, Queen's Hospital, Birmingham.

Kidd, E., M.B., B.S. Durh., Certifying Surgeon under the Factory and Workshop Acts for the Washington district of the county of Durham.

Marnoch, J., M.B., C.M. Aberd., a Medical Referee under the Workmen's Compensation Act for the Sheriffdom of Aberdeen, Kincardine, and Banff.

McKendrick, A., F.R.C.S. Edin., D.P.H., a Medical Referee under the Workmen's Compensation Act for the Sheriffdom of the Lothians and Peebles.

Vacancies.

For further information refer to the advertisement columns.

Aberdeen Royal Asylum.—Temp. Jun. Asst. P. £250.

Ashton-under-Lyne District Infirmary.—H.S. £200.

Bedford County Hospital.—H. S. £200. Asst. H.S. £150.

Birmingham Education Committee.—Part-time M.O.

Birmingham and Midland Ear and Throat Hospital.—H.S. £200.

Birmingham General Hospital.—H.P. £100. H.S. to Special Depts. £125. H.S. £100.

Blackburn and East Lancashire Royal Infirmary.—Third H.S. £250.

Blyth Urban District.—M.O.H. and Sch. M.O. £800.

Bournemouth, Royal Victoria and West Hants Hospital.—Hon. Sen. and Jun. M.O.'s.

Bradford Royal Infirmary.—H.S. £200.

Burnley County Borough.—Tuberc. O. and Director of Municipal Laboratory. £650.

Burnley, Victoria Hospital.—H.S. £200.

Cambridge, Adenbrooke's Hospital.—H.S. £130.

Cardiff, King Edward VII. Hospital.—H.S. £200.

Charing Cross Hospital, Agar-street, W.C.—Med. Reg. £150.

Chester, City of.—Asst. M.O.H. £500.

Colchester, Essex County Hospital.—H.S. £200.

East London Hospital for Children and Dispensary for Women, Shadwell.—Cas. O. £120.

Eday, Orkney.—M.O. £9 per week.

Enfield Education Committee.—Sch. M.O. £500.

Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—Asst. H.S. £150.

Great Northern Central Hospital, Holloway-road, N.—Clin. Asst. £1 1s. per session. Dental S.

Halifax, Royal Halifax Infirmary.—Third H.S. £200.

Hospital of St. John and St. Elizabeth, 40, Grove End-road, N.W.—Asst. S.

Huddersfield County Borough.—Asst. M.O.H. £500.

Leeds Public Dispensary.—Sen. Res. M.O £200.

Leeds University (Leeds Maternity Hospital).—Tutor in Obstetrics and Res. M.O. £300.

Leicester Royal Infirmary.—H.S. £200.

London County Council.—Asst. M.O. for Mental Hosp. Service. £300.

London Temperance Hospital, Hampstead-road, N.W.—Asst. Res. M.O. £120. Surg. Registrar. 40 guineas.

Lucknow University, India.—Prof. of Pathology. Rs.1200 a month. Prof. of Physiology. Rs. 1400 a month.

Manchester, Ancoats Hospital.—Res. Surg. O. £250.

Manchester Children's Hospital, Pendlebury.—Res. M.O. £150.

Manchester Ear Hospital.—Hon. Asst. S. Hon. Radiologist.

Manchester Royal Infirmary, Central Branch, Roby-street.—Female Res. M.O. £200.

Margate, Royal Sea-Bathing Hospital for Surgical Tuberculosis.—Female Surg. £200.

Middlesex Hospital.—Cas. M.O. £104.

Mildmay Mission Hospital, Austin-street, Bethnal Green, E.—Res. M.O. £250.

Newcastle-upon-Tyne City Mental Hospital, Gosforth.—Jun. Asst M.O. £400.

Newport, Mon., Royal Gwent Hospital.—H.S. £200.

Nottingham General Hospital.—Res. Cas. O. £250.

Oxford, Radcliffe Infirmary and County Hospital.—Cas. H.S. £200.

Portsmouth, Royal Portsmouth Hospital.—H.S. £150.

Reading, Royal Berkshire Hospital.—Second H.S. £200.

Royal Free Hospital, Gray's Inn-road, W.C.—Two H.P.'s. £50.

Royal Naval Medical Service.—Surg.-Lieuts. 26*s.* 6*d.* per diem.

St. Mary's Hospital, Paddington, W.—Cas. P. £100.

Saint Pancras Dispensary, Oakley-square, N.W.—Res. M.O. £225.

Salford Royal Hospital.—H.S. Cas. H.S. Each £150.

Seamen's Hospital, Albert Dock, Connaught-road, E.—H.S. £150.

Sheffield, East End Branch of the Children's Hospital.—Female H.S. £150.

Southampton Free Eye Hospital.—H.S. £200.

Southampton, Royal South Hants and Southampton Hospital.—Jun. H. S. £150.

Stroud General Hospital.—H.S. £200.

Sydney University, New South Wales, Australia.—Lecturer in Veterinary Anatomy and Surgery (including Obstetrics). £500.

Union of South Africa Government.—Asst. P.'s in Mental Hospital Service. £400.

West London Hospital, Hammersmith-road, W.—P. Neurologist.

Westminster Hospital.—H.P. H.S. Asst. H.P. Asst. H.S. Med. Registrar. £50.

THE Chief Inspector of Factories announces the following vacant appointments: Ruabon (Denbigh), West Drayton (Middlesex).

THE Home Secretary gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, for the Falmouth and Truro, Helston, Newquay, Penzance, Redruth, and St. Austell County Courts, in Circuit No. 59. Applications for the post should be addressed to the Private Secretary, Home Office, and should reach him not later than July 13th, 1921.

Births, Marriages, and Deaths.

BIRTHS.

KEYNES.—*On June 17th, at 10, Boundary-road, N.W. 8, to the* wife of Geoffrey Keynes, *F.R.C.S. Eng.—a son.*

LEATHART.—On June 14th, at Tollemache-road, Birkenhead, the wife of P. W. Leathart, M.B., B.C., of a son.

PLATTS.—On June *13th, at Clifton Lawn,* York, *the wife of* S. Goodman Platts, M.B., of a daughter.

QUICK.—On June 13th, at Varfell, Eaton-crescent, Swansea, the wife of Hamilton E. Quick, M.B., F.R.C.S., *of a daughter.*

RIGGALL.—On June 20th, at 31, Wimpole-street, W. 1, the wife of Robert M. Riggall, L.R.C.P. Lond. and Edin., of a daughter.

MARRIAGES.

ALTON—THIVE.—On June 14th, at Christiania, Edgar Hepworth Alton, L.R.C.P. & S. Edin., of King's Norton, Birmingham, to Ida Thive, eldest daughter of the late Ludovick Riordan, of Porsgrund, Norway.

CLARKE—TYRWHITT DRAKE.—On June 16th, at the Abbey, St. Albans, Sidney H. Clarke, M.D., of Longbutts, St. Albans, to May Gladys, youngest daughter of the late Rev. W. T. Tyrwhitt Drake *and* of Mrs. Tyrwhitt Drake, of Borogate, St. Albans.

CONNOR—LEES.—On June 11th, at the British Embassy Church, Paris, Brevet Lieut.-Colonel Frank Powell Connor, D.S.O., F.R.C.S., I.M.S., to Grace Ellen, daughter of Reginald O. Lees, *late Director,* Indian Government Telegraphs.

KEYMS—BENNETT.—On June 16th, at St. James', *Piccadilly,* J. J. Keyms, L.R.C.P. & S. Irel., to Alice, second daughter of the late Frank Bennett, of Cregane Manor, Rosscarbery, Co. Cork.

NOON—SOUTH.—On June 18th, at St. Peter's, Crawley, Charles Noon, F.R.C.S., to Cicely, eldest *daughter* of F. W. South, of Ifield, Sussex.

TAYLOR—LE MAISTRE.—On June 14th, at the Parish Church, Everingham, Harold Bourne Taylor (late Captain, R.A.M.C., M.R.C.S., L.R.C.P., to Francesca Maria, only daughter of Rev. *Sylvester and* Mrs. le Maistre.

Notes, Short Comments, and Answers to Correspondents.

REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1918.[1]

THE average strength of European troops (Regulars and Territorials) in India during 1918 was 87,982, as compared with 80,825 in the previous year, and 60,110 in the pre-war quinquennium 1910–14. For the whole force the admissions to hospital averaged 1030·2 per 1000, the deaths 16·19, the invalids sent home 22·81, and the average constantly sick, 60·00. All of these ratios are considerably higher than in any of the years immediately preceding; in 1917 the corresponding figures had been 771·7, 4·83, 16·54 and 45·00 respectively; *in the pre-war quinquennium* (1910–14) they had been 567·2, 4·51, 7·03 and 30·13. There has been no such high admission-rate since 1903 (when it was 1035·5); no such high death-rate since that of 1898 (20·31), no such invaliding since 1907 (25·47), and no such constantly sick ratio since that of 1903 (63·17).

Effect of War Conditions on the British Garrison.

The Director of Medical Services in India, in his introductory remarks, points out that, in considering the statistics of 1918, it is necessary to bear in mind the manner in which war conditions had affected the British Garrison; the standard of recruitment was lower, the more fit men had passed on to the Expeditionary Forces, leaving the debilitated behind, and invaliding had been delayed owing to shipping difficulties. *All the principal military* stations had increased ratios for admission to hospital and death, as compared with the previous year, with the one exception of Rangoon; and for average constantly sick, *except Rawal Pindi.*

The main cause of this increase was the epidemic prevalence of influenza, for which there were 19,308 admissions and 775 deaths, the ratios per 1000 strength being 210·5 and 8·81. The disease was introduced into the country *through the port of Bombay, where it appeared first among* the civilian population in the middle of June, and among the military immediately after. This epidemic abated on July 3rd, but a second outbreak started in September, and lasted into November, this being more severe than the first wave. *All the large military stations suffered;* the garrison most severely affected was that of Ahmednagar, where the influenza admissions reached the very high ratio of 459·8 per 1000 strength, the death-rate from this cause being 11·70 per 1000, and the case-mortality 2·51 per cent.; other large garrisons, with an admission-rate over 300 per 1000, were Meerut (392·0), Lahore (392·5), Colaba (376·4), Nowshera (360·5), Rawal Pindi (321·3) and Peshawar (313·0). The highest influenza death-rates were experienced at *Dalhousie* (19·20 per 1000, with a case-mortality of 8·37 per cent.), Nowshera (also 19·20, with a case-mortality of 5·33 per cent.), Peshawar (19·15, case-mortality 6·12 per cent.), Delhi (18·93, case-mortality 7·16), and Lahore (18·55, case-mortality 1·73). *The most* severe type of the disease appears *to have been experienced* at Quetta, where, though the admissions were not in a higher ratio than 152·4 per 1000, the death-rate was 13·67, giving a case-mortality of 8·97 per cent.—higher than that at *Dalhousie. On the other hand* Colaba, with the high admission-rate just mentioned (376·4), had the low death-rate of 4·31, giving a case-mortality of only 1·15 per cent.; Lucknow, with 279·0 admissions per 1000 had a case-mortality of only 1·09 per cent. Rangoon (no doubt, from its *detached situation)* suffered less than any other large station; the influenza admissions were only 72·4 per 1000, and there was only one death (0·98 per 1000). Two points of interest are mentioned in *regard* to this epidemic: (1) the streptococcal element was omitted in the vaccines prepared, as a result of discussion at a conference of bacteriologists, this organism not having been often found to be present; (2) there was no mention of the occurrence of *hæmorrhages,* as had been reported in other countries.

Malaria the Chief Cause of Sickness.

In spite of the prevalence of influenza, malaria retained its position as the *chief* cause of sickness and inefficiency among British troops in 1918. The admissions numbered 23,687 (equal to 26·13 per cent. of the total admissions for all causes), and were in a ratio of 269·2 per 1000 of total strength, as compared with 227·9 in 1917, and 117·2 in the pre-war quinquennium 1910–14.

---

[1] Calcutta: Superintendent of Government Printing. 1920.

It is pointed out, however, that the total admissions for malaria have probably been increased during each year of the war by the inclusion of relapse cases whose infections were contracted overseas, and whose statistics should more correctly be debited against the Expeditionary Forces. Every effort has been made to keep these statistics distinct; but so long as practical means are not *available to distinguish between relapses and fresh infections* a small error must occur, which may be in part or in whole counter-balanced by the cases which contracted their infection in India, but did not exhibit the disease until they were absorbed into the Expeditionary Forces.

Secunderabad had an admission ratio for malaria of 965·2 per 1000, the actual number of cases being 2998; the disease was of a very mild type, and not a single death occurred; at this station No. 8 Reserve Battalion, with a strength of 1451, had 1762 admissions for malaria (1213 per 1000). Various drainage works were carried out, and *it is stated that the "comparative absence of fresh infection* during the latter half of the year is promising," in spite of the increased rainfall. Mosquito-nets are authorised in the plains for all British troops and their families. It is not stated whether or no they are used. The issue of quinine as a prophylactic is left to the discretion of the medical authorities. It is not easy to see what other course could be adopted. As malaria is undoubtedly a preventable disease, the old query—"If preventable, why not prevented?" will continue to be asked; if the sanitary measures required are carried out mosquitoes would cease to be prevalent; if quinine were administered the troops would be rendered immune; if mosquito-nets were used they would be protected. The results that have been obtained in Italy, Panama, and elsewhere have proved beyond question that under the most difficult conditions of environment satisfactory prophylaxis is practicable. Peshawar cantonment is referred to in the Sanitary Commissioner's report in the following words: "The presence of a highly infected civil population and the existence of *kutcha* drains combined with irrigation is sufficient to account for the incidence of malaria." There is no hint at any need for action.

The Enteric Fevers.

For "enteric fevers," or "enterica," there were 663 admissions and 62 deaths, as compared with 276 and 33 respectively in 1917, and 227 and 26 in 1910–14; the ratios per 1000 were 7·5 and 0·70 in 1918, 3·4 and 0·41 in 1917, and 3·3 and 0·37 for 1910–14. Of the total cases in 1918 only 97 (with 23 deaths) were returned as "typhoid"; 209 (with 8 deaths) and 8 (with no deaths) were "paratyphoid" A and B respectively; and 349 (with 31 deaths) are classed in an "enteric group," which now includes cases formerly returned as pyrexia of uncertain origin, "P.U.O.," that is, "cases from which the specific organism could not be recovered, [but which] may be diagnosed on clinical grounds or on a rising Widal reaction." Eliminating this "enteric group," there remain 314 admissions for typhoid and paratyphoid A and B, with 31 deaths, 23 of these being due to typhoid and 8 to paratyphoid A. By far the largest number of admissions occurred at Bangalore (127, or 14·4 per 1000), where there were 71 cases in June, July, and August, an additional 30 in May and September, but only 26 during the remaining seven months of the year. Of the total number 23 (mostly among furlough men) had probably not contracted infection in Bangalore itself. The South Lancashire Regiment, 6th Battalion, suffered most, with 23 cases and 2 deaths. A particular cookhouse appeared to be the source of infection, and on bacteriological investigation a soldier was found to be a carrier of *B. paratyphoid A*, and was transferred to the enteric convalescent depot at Wellington. The disease prevailed throughout the station, and carriers played a considerable part in the spread of infection; flies were also abundant and the disease was present among the civil population. At Peshawar, Kirkee, Poona, and Lahore there was also excessive prevalence, though not a high mortality, except at Lahore, where 11 out of 33 cases were fatal.

Mortality from Other Diseases.—Home Invaliding.

For dysentery, colitis and diarrhœa the combined admission ratio was 49·2 per 1000, compared with 24·3 for the pre-war quinquennium (1910–14); the corresponding death ratios were 0·30 and 0·22. At Secunderabad the dysentery admissions and deaths were 61·7 and 0·32 per 1000, and for diarrhœa 32·2 admissions, with no death. Drinking-water supplies at various railway stations were investigated by local committees. It is regrettable that the incidence of venereal diseases (62·5 admissions per 1000) again shows a marked increase; in 1909 the admission ratio had been 67·8; in 1915 it had fallen to 29·1; in 1917 it was 52·0. Special attention has been given to early detection of the disease by regular inspection of new arrivals, and by surprise inspections, and the men have been encouraged to seek early treatment.

There were only 8 cases of plague (4 fatal). This is a good omen. For cholera there were 91 admissions, with 37 deaths (1·0 and 0·42 per 1000); 32 cases occurred at Poona and 18 at the neighbouring station of Kirkee, with 10 deaths at each station. The Kirkee water-supply at *Pashan lake was reported to be infected; but the water* was chlorinated at the waterworks and again in the British lines, and was not looked upon as the source of infection. A few days later 23 cases were admitted to the Station and King George's Hospitals at Poona. The milk was suspected, but no definite evidence of infection was obtained.

There were 911 admissions for heatstroke among British troops throughout India in 1918, with 97 deaths (10·4 and 1·10 per 1000). Of these cases 373, or 41 per cent., with 2 deaths, occurred at the single station of Nowshera, 114 in the North Staffordshire Regiment, and the remainder *among the R.A. and Machine Gun Corps; one-fifth of the* whole strength of the station appear to have been affected. The cases exhibited all degrees of severity, from simple exhaustion to the major type with cerebral symptoms and hyperpyrexia. No details are furnished as to the circumstances causing, or accompanying, this remarkable visitation, except that during June, July, and August abnormal dry and wet bulb temperatures were recorded. Pulmonary tuberculosis caused 154 admissions to hospital and 18 deaths, the ratios being 1·8 and 0·20 per 1000 respectively, a slight increase on those for the previous year (1·5 and 0·16, and the pre-war quinquennium, 1910–14 (1·1 and 0·16); there was no special prevalence at any one station. Diphtheria caused 90 admissions (of which 41 were at Quetta, from a newly arrived draft); there were only two deaths.

At the Kasauli and Coonoor Institutes 313 men and 45 women and children were treated for dog-bite; there were no deaths. Small-pox caused 117 admissions and 18 *deaths, giving ratios of 1·3 and 0·20 per 1000.*

The total number of men invalided home for all causes was 2007, being in a ratio of 22·8 per 1000, as compared with 16·5 in 1917, and 11·0 for the decennium 1908–17; the chief causes were heart disease (288), diseases of the nervous system (139), epilepsy (55) and insanity (130), malaria (147), and pulmonary tuberculosis (126).

Officers, Women, and Children.

The average strength of officers with British units was 4524, among whom the hospital admission-rate was 1344·6, and the death-rate 15·92; the corresponding ratios for 1917 were 965·5 and 7·03 per 1000, and for the pre-war quinquennium, 1910–14, 567·5 and 5·14. Out of the whole number of 72 deaths among officers 30 were due to influenza and 8 to pneumonia; there were 59 cases of typhoid, giving a ratio of 13·0 per 1000, the corresponding ratio for non-commissioned officers and men being 7·5 per 1000; only one officer died from this disease. Among the women (average strength, 1481) the admission- and death-rates were 603·0 and 24·98; anæmia and debility (129 per 1000), influenza (82·4), and malaria (44·6) were the chief causes of sickness; and pneumonia (4·73), pulmonary tubercle (2·03), and enteric fever (1·35) the chief causes of death. Among the children (average strength, 2624) the chief causes of illness were influenza (53·4 per 1000), malaria (51·4), and bronchitis (48·0); the corresponding death ratios being 1·52, 0·38, and 0·38 respectively. The admission and death ratios for all causes were 432·9 and 20·20 per 1000 respectively; for 1917 these ratios had been 355·6 and 12·17.

INDIAN ARMY.

The average strength of Indian troops in 1918, including those in China, but "excluding those under field-service conditions," was 341,458, as compared with 191,242 in 1917, and 130,261 in the pre-war quinquennium, 1910–14. The admissions to hospital reached the enormous total of 292,393, being in a ratio of 856·3 per 1000; the deaths numbered 9959 (29·17 per 1000); the ratios for invaliding and average constantly sick were respectively 19·2 and 40·7. These ratios (except that for invaliding) are much in excess of those for 1917, when the corresponding figures were 741·4, 11·51, 17·9, and 34·3; and, if compared with the average of the five years (1910–14) before the war, the increase is very great; the admissions to hospital during that period averaged 544·6, the deaths only 4·39, the invalids only 5·4, and the average constantly sick 20·7 per 1000.

Influenza, Malaria, and Pneumonia.

The great increase in admissions and mortality is largely accounted for by a widespread epidemic of influenza, which caused 46,715 admissions and 5200 deaths (136·8 and 15·23 per 1000). At Dera Ismail Khan there were 443·6 influenza admissions per 1000 strength, but the case-mortality ratio was only 1·56 per cent., *giving a death-rate* of 6·92 per 1000. At Risalpur, on the North-West Frontier, with 231·8 influenza admissions per 1000, the case-mortality was 16·43, giving a death-rate of 38·59 per 1000. At Kirkee, with the very moderate admission ratio of 68·5 per 1000, the deaths amounted to 32·58 per 1000, giving a case-mortality of 47·57 per cent. After influenza, malaria was the most frequent cause of admission to hospital (129·7 per 1000), but showed much improvement on the figures for the two years preceding (181·6 in 1917 and 200·7 in 1916), though higher than the ratio for 1910–14, which was 113·3. The mortality was 1·00 per 1000. At Tank and Fort Sandeman the admission ratios were highest (1280·2 and 1127·4); no specially infected area was discovered at either place. Attention is called to the fact that Secunderabad "does not figure among the ten worst stations this year." This is ascribed to the effect of drainage measures which were *commenced in* 1917 and consisted briefly in the drainage of the Picket and other tanks and the substitution of dry for wet cultivation. The admission ratio was 141·4, *compared with 518·4 in 1917*; this mild incidence may also be compared with the excessive prevalence among British troops (965·2) at the same station *already alluded to*.

Pneumonia caused an admission-rate of 19·6, and a death rate of 6·02 per 1000; this, as usual, was the most fatal disease for native troops (influenza excepted, which it so frequently accompanies), and to this cause probably many of the deaths recorded under pneumonia may be attributed, though efforts were made to differentiate between deaths due to primary pneumonia and pneumonia as a complication.

Tuberculosis; Diarrhœal Diseases; Plague.

Pulmonary tuberculosis (2·5 admissions per 1000, as compared with 2·1 in 1910-14) has not much increased, though the death-rate (0·63) is much heavier than that of the former period (0·22). As usual, Gurkha troops suffered the most (5·4 admissions and 1·90 deaths). The group of diarrhœal *diseases (dysentery, colitis, and* diarrhœa) showed a very great increase (as compared with 1910–14) *among Indian* as with British troops; the admissions and deaths for the three affections combined amounted to 68·4 and 0·45 per 1000 *respectively, as compared with 33·5 and* 0·14 in the pre-war period. Venereal diseases caused 18,125 admissions (58·1 per 1000), also a considerable increase over the ratios for 1916 and 1917, which were *40·1 and 45·0; in 1910–14* the ratio had been 14·8. At Deolali the admission ratio was 361·8, and at Bombay 242·4. Plague caused 121 admissions and 62 deaths *(0·4 and 0·18 per 1000), compared* with corresponding ratios of 0·60 and 0·30 in 1917, and 0·30 and 0·15 in the pre-war quinquennium. There was an appreciable reduction in the admissions for *cholera* (85, or 0·2 per 1000) compared with the previous year (0·7), and the death-rate (0·13) was less than *half that of* 1917 (0·29); the case-mortality, however, was high (52·94 per cent.); there was no epidemic prevalence. *Enterica* (0·8 and 0·28 cases and deaths per 1000) also showed a reduction in cases, though the deaths were *more in number* than in 1917.

GENERAL POPULATION.

For British India, as a whole, the birth-rate is recorded as 35·35 per 1000, as compared with 38·05, the average *of the preceding five years*: but it is stated that this fall is due mainly to interference with registration on account of the influenza epidemic. The highest ratios were recorded in Delhi (47·92) and the Central Provinces and Berar (43·21); the lowest in Ajmer-Merwara (26·35) and Madras Presidency (28·9). The general death-rate was 62·16 per 1000, ranging from 38·10 in Bengal and 30·20 in Lower Burma to 102·60 in the Central Provinces and Berar, and 114·78 in Ajmer-Merwara. The infantile mortality (under 12 months) was lowest in Assam (21·6 per *100 births) and* Bengal Presidency (22·8), and highest in Bombay city (59·6); in Madras city it was 35·5, and in Calcutta 28·0.

Much useful work is being carried out in various cities towards the prevention of infant mortality, *by the provision* of trained midwives, the establishment of dispensary centres, and the appointment of municipal nurses and *health visitors*. The total number of births is stated as 8,130,560, and the total deaths 14,895,801 (62·46 per 1000). *Of this latter* total, 11,131,111 (46·69 per 1000) are returned as "fevers," amounting to 74·7 per cent. of the total *mortality*, and of these deaths 7,402,070 were registered during *the last* quarter of the year, when influenza *was prevalent*. *It is* stated that "there is no evidence to show that 1918 was for malaria in any sense an *exceptional* year," and it is suggested that the mortality directly and indirectly due to influenza was near the mean *between* (1) "the excess in the mortality from all causes between June 1st and Dec. 31st over the five years' mean"—6,812,633; (2) an estimate obtained "by subtracting from the total mortality from all causes the deaths registered as due to the chief epidemic diseases—plague, cholera, and small-pox, and comparing this figure with one similarly obtained for the previous quinquennium"; (3) the excess mortality from "fevers" and respiratory diseases over the average for the five years. The respective figures for the two latter estimates are 7,301,178 and 7,151,971; the mean of the three, 7,089,691, is adopted by the Sanitary Commissioner. The heaviest incidence, judging by the excess mortality, was experienced by the Central *Provinces and Berar* (66·1 deaths per 1000), Ajmer-Merwara (59·5), Delhi province (56·6), and Bombay (51·9); in Coorg the excess was only 11·5, and in Bengal *only* 8·5 *per* 1000. Speaking generally, districts on or near the sea coast had a comparatively low mortality (under 20 per 1000). As to the origin of the epidemic, *the Sanitary Commissioner states that* "the case for the introduction of infection by shipping must be left as unproven. *The case for endemic loci is* just as *uncertain* . . . . *Although* it cannot be stated definitely that influenza existed in India before the first official intimation of its existence early in June in Bombay, *yet the possibility* cannot be *excluded*."

Many other matters of interest are dealt with in this exhaustive report, which extends to 322 pages *and is* accompanied by an excellent map of India and very numerous diagrams and tables. The sections dealing with the European and Indian Armies are contributed by the Director of Medical Services; *for the remainder, referring* to the general population, jails, &c., Lieutenant-Colonel F. H. G. Hutchinson, I.M.S., *Sanitary Commissioner* with the Government of India, is responsible.

NATIONAL BABY WEEK.

THE *fifth birthday of National Baby Week, to be celebrated* on July 1st, and for a week thereafter, will again give to the nation an opportunity of considering the needs of its children, and the steps which are—or are not—*being taken* to meet those needs. Birthdays have their uses, *and not least in that* they serve as landmarks, from whence one can survey the progress made, or *the ground lost, in the past* years. In this fifth year of its existence the National Baby Week Council, in common with other societies engaged in child welfare work of one sort or another, is able to rejoice in the decreasing infant mortality rate, the figure for 1920 (80 per 1000 births) being the lowest recorded. Many influences have *contributed to bring about* this satisfactory result, and the National Baby Week Council feels that it may claim a not inconsiderable share of the credit. Since the first Baby Week held in 1917, the Council has worked steadily to make *known* the position of child welfare in this country. Its work is wholly that of education and propaganda: it exists *to draw* attention to the child, its needs, its disabilities, and its possibilities. Each year the Council has *concentrated on some* particular aspects of child welfare, thus focusing attention on one or two important points, not *suggesting that* by so doing it has covered the whole field of child welfare, but rather excluding some important *points in order* that others may for the time being be emphasised. Thus, in its first year, attention was *drawn* to the facts of infant mortality, and the importance of infant life to a nation which was daily *losing the flower* of its manhood in the great war. In 1918, the teaching of mothercraft was the slogan; in 1919, the *creation of new* and better ideals of babyhood and the importance of natural feeding; and in 1920, the necessity for liquor control in the interests of maternity and child welfare, the better care of the unmarried mother and her child, and the urgent need for some scheme of pensions for civilian widows with young children.

This year the Council is emphasising three matters of great importance, two of which have already been *emphasised in* previous years: 1. The importance of natural feeding, in view of the fact that a naturally-fed baby *has twice as* good a chance of surviving as an artificially-fed baby. 2. The urgent need for some scheme *of pensions for* civilian widows with young children, which will enable the children to remain in the care of *their own* mothers, instead of *being entrusted* to the much less efficient and much more expensive care of public *institutions*. 3. The prevention of infantile blindness and the importance of notification and *treatment* of ophthalmia *neonatorum*. This year, too, as last year, the Council is identifying itself with the Children's Era Movement, which *aims* at the closer coöperation of all existing agencies for the betterment *of the* child—religion, health, *recreation*, education, &c. While the Council rejoices with other child welfare societies in the lowered *infant mortality* rate, it realises that in success there is an element of danger. Those who care for the children of the nation must *not* be content with this lowered rate: their aim must be still further to reduce it. It must be rememhered that our daughter countries can point to a still lower rate—for instance, the mortality rate for the whole Commonwealth of Australia in 1919 was only 69·21 per 1000 births for children under one year. The aim of the Baby Week Council is not only to reduce the death-rate, but also to reduce the correspondingly high *damage*-rate among the children who manage to survive. It has been said that every social problem is a problem of child welfare. It is certainly true that every social problem takes its toll of child lives. Bad housing, defective sanitation, alcoholism, venereal disease, industrial employment of mothers, all these must be held responsible to an enormous extent for the heavy damage-rate among little children in this country.

A criticism sometimes heard suggests that the mothers resent the help offered by welfare societies and regard it as interference. In a few isolated cases perhaps they do, but the increase in the number of successful infant welfare centres and similar agencies in the country is evidence of the fact that these centres, schools for mothers, Baby Week, and so forth, supply a felt need.

CHARTERED SOCIETY OF MASSAGE AND MEDICAL GYMNASTICS.

A YEAR ago an amalgamation took place under Royal Charter of the Incorporated Society of Trained Masseuses and the Institute of Massage and Medical Gymnastics with the righteous aim of advancing the profession of massage in the broad sense, and of affording protection to those qualified to practise it. The following list of recognised training centres, with the subjects in which classes are held, has now been drawn up and may be found useful to our readers. Massage=M. Medical Electricity=E. Medical Gymnastics=G.

Hospital Schools: London.

	Subjects taught.
City of Westminster Infirmary	M.
Fulham Infirmary	M.
Guy's Hospital	M. E. G.
King's College Hospital	M. E. G.
Lambeth Infirmary	M.
Maida Vale Hospital	M. E.
Middlesex Hospital	M. E. G.
National and University College Hospitals	M. E. G.
Queen Mary's Hospital for the East End	M.
Royal National Orthopædic Hospital	M. E. G.
St. Thomas's Hospital	M. E. G.
West End Hospital	M. E. G.
Westminster Hospital	M. E. G.

Provinces.

Manchester, Ancoats Hospital	M. E.
York, County Hospital	M.
Buxton, Devonshire Hospital	M. E.
Ipswich, East Suffolk and Ipswich Hospital	M. E.
Birmingham, General Hospital and Orthopædic Hospital	M. E. G.
Bristol, General Hospital	M. E. G.
Nottingham, General Hospital	—*
Worcester, General Infirmary	M.
Cardiff, King Edward VII. Hospital	M. E.
Norwich, Norfolk and Norwich Hospital	M.
Carshalton, Surrey, Queen Mary's Hospital	M. E.
Newport, Mon., Royal Gwent Hospital	M.
Bradford, Royal Infirmary	M. E.
Bristol, Royal Infirmary	M.
Leicester, Royal Infirmary	—*
Liverpool, Royal Infirmary	—*
Manchester, Royal Infirmary	M. E. G.
Bath, Royal Mineral Water Hospital	M. E.
Brighton, Royal Sussex County Hospital	M. E.
Newcastle-on-Tyne, Royal Victoria Infirmary	M. E. G.
Salford, Salford Royal Hospital	M. E.
Shrewsbury, Salop Infirmary	M.
Rochester, St. Bartholomew's Hospital	M. G.
Oswestry, Shropshire Orthopædic Hospital	M. E. G

Ireland.

Dublin, Adelaide Hospital	—*

Scotland.

Glasgow, Western Infirmary	M. E. G.

* Not training at present.

Colleges and Schools: London.

Misses Bear, Queen Alexandra House Gymnasium, Kensington Gore, S.W.	M. G.
Misses Brown and Humble, Training College for Remedial Gymnastics, and Massage, 36, Pembridge Villas, W. 11	M. E. G.
Miss Joyce Buckley, School of Massage and Swedish Remedial Gymnastics, 12, Buckingham-street, Strand, W.C. 2	M. E. G.
Mrs. Manning Carr, 3, Bedford-place, W.C. 1 (Evening Classes)	E. G.
Mrs. Penfold, Hampstead Medical Gymnastic College, 27, Canfield-gardens, N.W. 6	M. E. G.
Miss Rose Morris, 2, Albany-terrace, Regent's Park, N.W.	M. E. G.
National Institute for the Blind (Massage Branch), 221, Great Portland-street, W. 1	M.
Miss Spelman Stanger, Denmark Hill Gymnasium, Sunray-avenue, Herne Hill, S.E. 24	M. G.
Mrs. Hoghton Stewart, London School of Massage and Swedish Remedial Gymnastics, Westminster Medical School, 12, Caxton-street, S.W.	M. E. G
Mr. T. W. Wall, Central London School of Massage for Men, 211, Great Portland-street, W. 1	M. E.
Miss Wilkie, Chelsea School of Physical Training (3 years' course), Manresa-road, S.W.	M. G.
Dr. Justina Wilson, Swedish Institute, 106, Cromwell-road, S.W.7	M. E. G.

Provinces.

Miss Chuck, School of Massage, 18, Falkner-square, Liverpool	M. E. G.
Miss Irene Marsh, Liverpool Physical Training College (2 years' course), Bedford-street, Liverpool	M. G
Miss Masters, Southport School of Massage, 22, Part-street, Southport	M. E.
Miss A. M. Poulter, School of Massage and Medical Gymnastics, 27, Cambridge-road, Hove, Brighton, Sussex	M. E. G.
Miss Weeks, 22, Pinecliffe-avenue, West Southbourne, Bournemouth	M.

Ireland.

Miss Despard, Lincoln Chambers, Dublin	E.
Miss Hogg, School of Massage and Medical Gymnastics, 12, Hume-street, Dublin	M. E. G.
Miss E. Sweeny, 15, Upper Mallow-street, Limerick	M.

Scotland

Misses Hastings and Ewart, School of Massage and Swedish Remedial Gymnastics, 20, Dublin-street, Edinburgh	M. E. G.

THE A.D.R.M.

ACCORDING to *La Presse Médicale* (June 4th), a useful way of fostering amical relations between medi men in France and other allied or friendly countries is contemplation. It has been suggested that the for a time of the children of medical men living in differen countries might conduce to the happiest results. As a pr paratory measure, an invitation has been issued by the Association pour le Développement des Relations Médical (A.D.R.M.) to those French medical men who would to take advantage of such an arrangement to send th names and addresses, and to indicate the town in or Spain to which they would like to send their children. Steps will then be taken to ascertain the names of docto in the countries mentioned who would like to participat in such an exchange. Among other suggestions accept by the Association, the general secretary of which is M Charles Béclard, Faculté de Médecine, 12, rue de l'Ecole d Médecine, Paris, was one by Mr. Desmarets that member travelling abroad should be entitled to receive letter from the committee introducing him to his colleague in foreign countries.

MUZZLING ORDERS.

THE most recent outbreaks of rabies in England at Southampton on June 6th and at Salisbury on June 7th There has been no recent outbreak of rabies in Sco In Wales the last outbreak of rabies occurred on Sept. 8 1920. The Minister of Agriculture states that it is no possible at present to give any indication as to when muzzling orders will be withdrawn from the schedule districts in the case of Southampton and Salisbury. No muzzling orders have been recently applied to Scot As regards Wales the muzzling order was withdrawn May 1st last.

INFANT MORTALITY IN THE WEST INDIES.

FIGURES relating to infant mortality in the parts America under British rule were recently given in the House of Commons by the Secretary for the Colonies follows:—

Colony.	Year.	Infantile mortality.*	Colony.	Year.	Infantile
Barbados	1919	306	Leewards (*cont.*)—		
Bermuda	1919	166	Nevis	1918	26
British Guiana	1919	185	Anguilla	1918	
British Honduras	1919	215	Trinidad	1919	1
Jamaica	1919	161	Windwards—		
Leewards—			Grenada	1920	1
Antigua	1918	177	St. Lucia	1919†	14
Dominica	1920	146	St. Vincent	1919†	11
St. Kitts	1918	255			

* The figure given is the number of deaths of children unde 1 year of age per 1000 living births.

† April-December.
